RP333

INDEX

Abbie, A. A. : Criteria for the Comparison of Skulls, 101
Abbot, A., et *al.* : Behaviour of Active Bacterial Antigens during the Induction of the Immune Response, 1257
Abdel-Latif, A. A., et *al.* : *In vivo* Degradation of Histamine-adenine Dinucleotide Phosphate to Histamine Ribonucleoside, 907
Abdoh, Y., and Nafissi, M. M., Free Amino-acid Content of Tobacco-seeds, 178
Aberdeen Meeting of the British Association for the Advancement of Science (Dr. R. B. Strathdee), 18
Abetti, G. : The Sun, second edition, *review* by J. Heywood, 840
Aborigines : Incidence of Pseudocholinesterase Variants in Australian (W. R. Horsfall *et al.*), 1115
Abraham, E. P., et *al.* : Production of a Cephalosporinase by *Pseudomonas pyocyanea*, 375
Absence of Free Iodotyrosines from the Plasma of the Rat (S. Lissitzky, J. Bismuth and C. Simon), 1002
Absorbing Components separated by Density Gradient Centrifugation : Apparatus for the Automatic Location of (J. G. Edwards and A. P. Mathias), 603
Absorption of Chlorhydroxyquinoline (F. M. Freeman and W. W. Heseltine), 703
Absorption of Chymotrypsin from the Intestinal Tract (B. L. Kabacoff, A. Wohlman, M. Umhey and S. Avakian), 815
21-cm Absorption of the Radiation from 3C273 (B. J. Robinson, K. J. van Damme and J. A. Koehler), 990
Absorption of Vitamin B12–Glutamic Acid Mixture (O. Heinivaara and I. Palva), 289 ; (F. S. Mooney and J. G. Heathcote), 290
Abstracts and Indexes in Science and Technology : Lists issued by the Borough of Lewisham Library, 231
Lists issued by the Manchester Technical Library, 231
Academy of Sciences : Annals of the New York, 101, Article 3 : Conference on Clean Surfaces, 238
Academy of Sciences of the U.S.S.R., re-organization of, 230
Accumulation of Amino-acids in Plant Cell Tissue Cultures (R. L. Wickremasinghe, T. Swain and J. L. Goldstein), 1302
Accumulation of Calcium and Strontium by Brown Trout in Waters in the United Kingdom (W. L. Templeton and V. M. Brown), 198, 199, *erratum*, 122
Accurate Time for Field Astronomy (W. A. Stepec), 135
Acetabularia mediterranea : Effects of Puromycin on Morphogenesis in Amphibian Eggs and (J. Brachet), 714
Acetone Solutes : Penetration of Seeds by (B. V. Milborrow), 716
Acetylcholine by Triethylcholine : Inhibition of Biological Synthesis of (G. Bull and B. A. Hemsworth), 487
Acetylcholinesterase activity of Capillary Blood Vessels in the Central Nervous System of the Rabbit (Lt. Col. J. C. Crook), 41
Acetylphenylhydrazine, Hæmoglobin and Erythrocytes : Oxidation of Reduced Glutathione by (Doris Balinsky and R. E. Bernstein), 187
Acid Hydrolysis of 2-substituted Methyl Glucopyranosides : Rates of (R. D. Marshall), 998
Acid Phosphatase Variants : A New Human Polymorphism : Red Cell (Dr. D. A. Hopkinson *et al.*), 969
Acid Ribonuclease in Liver Cell Sap (E. Reid and J. T. Nodes), 176
Acid Strength : Pertechnic Acid : an Aperiodic Variation in (C. L. Rulfs *et al.*), 66
Acred, P., *et al.* : A New Approach to Studying the Protein-binding Properties of Penicillins, 758
Acrylamid Gels : Micro Method of Haptoglobin Typing using (A. Baumgarten), 490
Actinomycete : 'Refuin' : a Non-cytotoxic Carcinostatic Compound Proliferated by a Thermophilic (M. D. Tendler and S. Korman), 501
Actinomycin and Proflavine : Inhibition of Ribonucleic Acid-Polymerase Reactions by (Dr. I. H. Goldberg *et al.*), 44
Actinomycin *D* and Puromycin : Action of Insulin on the Isolated Rat Diaphragm in the Presence of (D. Eboué-Bonis *et al.*), 1183
Actinomycin *D* and Vaccinia Virus Infection on HeLa Cells (A. J. Shatkin), 357
Action of 5-Bromo-3-*sec*-Butyl-6-Methyluracil as Regards Replacement of Thymine in Mouse DNA (J. W. McGahen and C. E. Hoffmann), 810
Action of Insulin on the Isolated Rat Diaphragm in the Presence of Actinomycin *D* and Puromycin (D. Eboué-Bonis, A. M. Chambaut, P. Volfin and H. Clauser), 1183
Action of Mercuric Chloride on Strained Keratin (J. L. Hoare and J. B. Speakman), 1091
Action Spectrum of Mitotic Ferrous Complex (Dr. J. E. Amoore), 38
Acton Society Trust, 1
Ada, G. L., et *al.* : Behaviour of Active Bacterial Antigens during the Induction of the Immune Response, 1257, 1259
Adams, D. M., et *al.* : Far-infra-red Absorption Spectra of some Complex Halides of Molybdenum and Tungsten, 278
Adenine, Adenine Nucleosides and Nucleotides on the Biosynthesis of Porphyrins by *Rhodopseudomonas spheriodes* : Inhibitory Action of (A. Gajdos and M. Gajdos-Török), 1093
Adenosine Diphosphate and Adenosine Triphosphate Content of Tissues infected by Tobacco Mosaic Virus : Nicotinamide-adenine Dinucleotides, (D. W. Sunderland and M. J. Merrett), 1116
Adenosine Triphosphatase : Evidence of the Mechanism of Ouabain Inhibition of Cation Activated (J. S. Charnock and R. L. Post), 910
Adenosine Triphosphatase Activity and Actin-binding Ability of L-Myosin and Heavy Meromyosin : Effect of Ultrasonics on the (M. Bárány, K. Bárány and H. Oppenheimer), 694
Adenosine Triphosphate : an Inhibitor of Generation of Thromboplastin (L. O. Pilgeram), 708
Adenosine Triphosphate Concentration in *Aerobacter aerogenes* : Effect of Starvation on (R. E. Strange *et al.*), 55
Adenosine Triphosphate Content of Tissues infected by Tobacco Mosaic Virus : Nicotinamide-adenine Dinucleotides, Adenosine Diphosphate and (D. W. Sunderland, M. J. Merrett), 1116
Adenosine Triphosphate in Muscular Contraction : Role of (I. Singh and N. V. Raju), 288
Adenosine Triphosphate under possible Primitive Earth Conditions : Synthesis of (Dr. C. Ponnamperuma *et al.*), 222
Adenovirus Particles and Soluble Antigens produced in the Presence of 5-Bromodeoxyuridine : An Analysis of (L. Kjellén *et al.*), 1210
Adenylsuccinase formed by Interallelic Complementation in *Neurospora crassa* : Sedimentation Behaviour of (C. W. H. Partridge and N. H. Giles), 305
Adinolfi, M., et *al.* : Evidence that 'Normal Incomplete Cold Antibody' is not a Gamma-globulin, 389
Adrenaline on Concentrations of Free Fatty Acids in Rat Heart and Diaphragm Muscles : Effects of Alloxan Diabetes and (P. B. Garland and P. J. Randle), 381
Adrenocorticotrophic Hormone : Total Synthesis of (R. Schwyzer and P. Sieber), 172
Adsorption Chromatography of Direct Azo Dyes (P. Raban), 596
Adsorption *in vitro* of Bovine Enteroviruses by Non-cultured Bovine and Human Tissues (M. La Placa), 1211
Adsorption of Krypton and Xenon on Evaporated Metal Films in Relation to the Determination of Surface Area and the Nature of Adsorbed Carbon Monoxide (D. Brennan, M. J. Graham and F. H. Hayes), 1152
Adsorption of Rabbit Antibody by Rat Tissue Mast Cells and Other Cells *in vitro* (R. Keller and E. Sorkin), 709
Advances in Astronautical Propulsion : Proceedings of a Seminar held in Milan by Instituto Lombardo Accademia di Scienze e Lettere in collaboration with the Advisory Group for Aeronautical Resarch and Development of Nato, 1960 (edited by Corrado Casci), *review* by D. G. King-Hele, 525
Advances in Carbohydrate Chemistry, Vol. 17 (edited by Melville L. Wolfrom), *review* by Dr. W. J. Whelan, 1124
Advances in Catalysis and Related Subjects, Vol. 13 (edited by D. D. Eley, P. W. Selwood and Paul B. Weisz), *review* by D. A. Dowden, 727
Advances in Clinical Chemistry, Vol. 5, (edited by Harry Sobotka and C. P. Stewart), *review* by Prof. J. N. Davidson, 946
"Advances in Experimental Embryology" : International Summer Course on, 540
Advances in Food Research, Vol. 11 (edited by C. O. Chichester, E. M. Mrak and G. F. Stewart), *review* by Dr. Magnus Pyke, 944
Advances in Horticultural Science and Their Applications : Proceedings of the XVth International Horticultural Congress, Nice 1958. Vols. 2 and 3 (edited by Jean-Claude Garnaud), *review* by G. P. Harris, 3
Advances in Ophthalmology, Vol. 13 (edited by E. B. Streiff), *review* by R. A. Weale, 1221
Advisory Council on Scientific Policy : Appointment of new members to the council, 1041
Aerobacter aerogenes : Biological Activity of a Brownish-Yellow Pigment produced from Vitamin B_{12} by (K. Helgeland *et al.*), 604
Effect of Starvation on Adenosine Triphosphate Concentration in (R. E. Strange *et al.*), 55
Aerobacter aerogenes and of Red Blood Cells after Freezing and Thawing : Similar Effects of Various Neutral Solutes on the Survival of (T. Nash *et al.*), 1113
Aeronautical Engineering : Dr. G. J. Hancock appointed reader in, 24
Dr. A. Simpson appointed lecturer in, 434
Aeroplane in the Civil and Military Fields : Future of the (Dr. S. G. Hooker), 886
Aerosol Congress, The fourth International, 962
Africa : Physics in (J. M. A. Lenihan), 749
After-images : Fragmentation of Patterned Targets when viewed as Prolonged (H. C. Bennet-Clark and C. R. Evans), 1215
Age Measurements of Antarctic Rocks (Queen Maud Land), (P. Pasteels and Sarah Deutsch), 996
Age of the Youngest Hydrated Halloysite in Kyushu (S. Aomine and N. Miyauchi), 1311
Ageing in Poikilotherms : Temperature and the Rate of (J. Maynard Smith), 400
Agricultural Research Council : A Blood Typing Service for Cattle, 644
Buildings for Poultry, 334
Prof. C. L. Oakley appointed a member of the Council, 748
Report No. 15, 1962, 854
Ahlert, G., et *al.* : Quantitative Relations between Ferritin and Siderin, 175
Ahmed, Y. Y., and McKenzie, J. : Changes in the Motor Neurones after administering Muscle Relaxant and Convulsant Drugs, 385
Air Catalyst Fluidized Bed : Variation of Bed Height with Bubbling in an (J. F. Richardson and L. Davies), 898
Air, Effects of, on Rabbit during surface cooling down to Cardiac Arrest (Dr. B. Broom), 1155
Air, Ground-level, and Human Lungs during Spring 1962 : Plutonium-239 and other Nuclides in (Dr. R. V. Osborne), 143
Akeson, W. H. : Application of the Arrhenius Equation to Rat Tail Tendon Collagen, 185
Akino, M., et *al.* : Occurrence of Two Different Enzymes in the Silkworm, *Bombyx mori*, to reduce Folate and Sepiapterin, 908
Albert, A., and Serjeant, E. P. : Resolution of a Racemic Pteridine during Paper Chromatography, 1098
Alcoholic Addiction : A Psycho-social Approach to Abnormal Drinking (Howard Jones), *review* by Dr. M. M. Glatt, 1023
Alcohol Mixtures : Equilibria in Water- (A. Johnson *et al.*), 692
Alcohol Preference in *BALB/c* Mice : Development of (R. Kakihana and G. E. McClearn), 511
d,l-Aldosterone, Effects of, on Renal Excretion of Water, Sodium, and Potassium induced by Renin (H. Croxatto, E. Labarca, and G. Cofré), 182
Alexander, D. P., *et al.* : Perfusion of the Viable Sheep Foetus, 183
Alexander, P., et *al.* : Influence of Temperature and Medium on the X-ray Sensitivities of Leukaemia Cells *in vitro*, 193
Alfalfa by Potato Leafhoppers : Amorphous Tumours induced in (D. K. Barnes and R. C. Newton), 95
Alga ; A Common Link between Photosynthesis and Respiration in a Blue-Green (L. W. Jones and J. Myers), 670
Alignment of Cirrus Clouds along the Magnetic Meridian (L. Kellner), 900
Alivisatos, S. G. A., *et al.* : *In vivo* Degradation of Histamine-adenine Dinucleotide Phosphate to Histamine Ribonucleoside, 907
Alkali and Cement Works : Inspection of, 751
Alkali Glasses : Solvated Electrons in (M. J. Blandamer *et al.*), 902

Alkali Metal Atoms : Mass Spectrometric Investigation of Reactions of Electronically Excited Neutral Particles with (Z. Herman and V. Čermák), 588
Alkali Metal Nitrates as Revealed by Differential Thermal Analysis : Physical Transitions of the (E. S. Freeman and D. A. Anderson), 63
Alkali Metal Nitrates by Light Ions of Kilovolt Energy : Decomposition of (S. R. Logan), 369 ; *erratum*, 1238
Alkaline Earth Monofluorides : Dissociation Energies of the (G. D. Blue *et al.*), 804
Alkaloids using Ultrasonic Energy : Isolation of (A. E. DeMaggio *et al.*), 1292
Alkanes : Energetics of Ion Molecule Reactions in (Dr. L. Kevan), 562
n-Alkanes in Mixtures of Saturated Hydrocarbons by Means of Gas Chromatography : Determination of (P. A. Schenck and E. Eisma), 170
Alkyl and Halo Substituents on the Homolytic Dissociation of Dibenzyl Hyponitrites : Effect of (J. B. De Sousa), 64
Alkyl Iodides : Effect of Electron Donors on the Isotopic Exchange between Aluminium (III), Gallium (III) and Indium (III) Iodides and (A. Polaczek and A. Halpern), 1286
Alkyltrimethylammonium Bromides for the Isolation of Ribo- and Deoxyribonucleic Acids : Use of (A. S. Jones), 280
Allan, A. H. : Sudden Changes in Amplitude and Phase of 16 kc/s Very-low-frequency Signal received in New Zealand, 582
Allegretti, N., and Vitale, R. : Influence of Bacillus Calmette-Guérin Infection on the Intensity of Homograft Reaction in Rats, 507
Allen, Dr. C. R., and Wright, Dr. P. G. : Limitations of Electronic Interpretations of Chemical Phenomena, 344
Allen, J., *et al.* : Effect of Diurnal Freeze-Thawing on Survival and Growth of Selected Bacteria, 1078
Allen, Dr. M. Delia : Apicultural Research, 651
Drone Production in Honey-bee Colonies (*Apis mellifera* L.), 789
Allen, Dr. N. L., *et al.* : The Associated Electrical Industries Levitron, 123
Allergology : Proceedings of the IVth International Congress of Allergology, October 1961 (edited by Ethan Allan Brown), *review* by Dr. J. Pepys, 629
Allibone, Dr. T. E. : *Obituary* on Prof. G. M. Petropoulos, 852 ; Programming and Utilization of Research Reactors : Proceedings of a Symposium held in Vienna, October 1961, Vols. 1 and 2, *review*, 208
Allison, A. C., and Nash, T. : Electron-donor or Electron-acceptor Properties and Carcinogenic Activity of Organic Molecules, 469
Allolobophora terrestris (Sav.) forma *longa* (Ude) and *Eisenia foetida* (Sav.) : Heat-death Temperature in (H. B. Miles), 826
Allotypic, Distribution of, Specificities among Rabbit γ-Globulin Molecules Genetically Defined at Two Loci (Dr. S. Dray, G. O. Young and Dr. A. Nisonoff), 52
Allotypy of an Immune Globulin in Rabbit Colostrum : Character and (A. Feinstein), 1197
Alloxan Diabetes and Adrenaline on Concentrations of Free Fatty Acids in Rat Heart and Diaphragm Muscles : Effects of (P. B. Garland and P. J. Randle), 381
Alloy Films : Epitaxial Oxide Growth on Thin Single-crystal Gold-Nickel (I. H. Khan and M. F. Francombe), 800
Alloy Steel and Nickel : Application of Atomic Absorption Spectroscopy to the Determination of Cobalt in Steel (G. L. McPherson *et al.*), 371
Allsopp, Dr. A. : Histogenetische Studien an den Blüten Einiger Phanerogamen, *review*, 733
Modern Methods of Plant Analysis, Vol. 5, *review*, 315
Alper, T., *et al.* : Dose-effect Relationships for Radiation Damage to Organized Tissues, 253
Al'pert, Ya. K. : Radio Wave Propagation and the Ionosphere, *review* by J. A. Ratcliffe, 940
Alsop, M., *et al.* : Formation and Properties of the Black Form of Carbon Disulphide, 756
Alteration of the Biochemical Effects of Ethidium Bromide by Exposure of Cells to Hypotonic Media (T. S. Kandaswamy and J. F. Henderson), 807
Altman, Dr. J. : Differences in the Utilization of Tritiated Leucine by Single Neurones in Normal and Exercised Rats : An Autoradiographic Investigation with Microdensitometry, 777
Altmann, H., *et al.* : *In vivo* Investigation of the Removal of Trace Elements from Nucleic Acids of Yeast by Ionizing Radiation, 823
Aluminium (III), Gallium (III) and Indium (III) Iodides and Alkyl Iodides : Effect of Electron Donors on the Isotopic Exchange between (A. Polaczek and A. Halpern), 1286
Aluminium (III), Gallium (III) and Indium (III) Iodides in Alkyl Iodides : Electrical Conductivity of Solutions of (A. Halpern and A. Polaczek), 1286
Aluminium Alloys : Electron-Probe Microanalysis of Anodic Oxide Films on (Dr. G. C. Wood *et al.*), 239
Aluminium Arsenide by a Vapour Phase Transport Reaction : Preparation of (D. E. Bolger and B. E. Barry), 1287
Alvarenga Prize Awarded for 1963, 540
Amber, George H., and Amber, Paul S. : Anatomy of Automation, *review* by Dr. E. M. Deeley, 520
Amber, Paul S., and Amber, George H. : Anatomy of Automation, *review* by Dr. E. M. Deeley, 520
Ambrose, E. J., *et al.* : Infiltration of Intra-abdominal Organs by Ascites Tumours, 188
American Management Association and the Society for the Advancement of Management, 518
Amino-acid Activating Enzymes of Rat Liver : Effect of Protein Depletion on (A. Mariani *et al.*), 378
Amino-acid, A New, γ-Hydroxyhomoarginine, in *Lathyrus* (E. A. Bell), 70
Amino-acid Pools : Proceedings of a Symposium on Free Amino Acids, 1961 (edited by Joseph T. Holden), *review* by Prof. E. F. Gale, 1124
Amino-acid Content of Tobacco-seeds : Free (Y. Abdoh and M. M. Nafissi), 178
Amino-acid Incorporation by Nuclear Ribonucleic Acid from Normal and Methylcholanthrene-treated Rats : Stimulation of (L. A. Loeb and H. V. Gelboin), 809
Amino-acid into Rat Liver Ribosomes : Stimulation by Rat Liver Ribonucleic Acid of Incorporation of (A. Korner and A. J. Munro), 489
Gamma-Amino-Butyric Acid of Different Regions of the Mauthner Neurone : Variation in the Sensitivity to (Dr. J. Diamond), 773
Amino-acids : Blood Corticosterone-levels in the Rat after Administration of (H. N. Munro *et al.*), 1182
Amino-acids, Amino-acid Polymers, Fatty Acids and Purines from Ammonium Cyanide : Formation of (Prof. C. U. Lowe *et al.*), 219
Amino-acids by Electron Spin Resonance at Very-low-temperature : Examination of Optically Excited (M. Ptak and P. Douzou), 1092
Amino-acids by Gas Chromatography and Electron Affinity Spectrometry : High-sensitivity Detection of (Dr. R. A. Lansdowne and Prof. S. R. Lipsky), 141
Amino-acids in Plant Cell Tissue Cultures : Accumulation of (R. L. Wickremasinghe *et al.*), 1302
Amino-Acids of Avian Liver : Thin-layer Chromatographic Separation and Quantitative Determination of Several Free (R. L. Squibb), 1216
Aminoacyl Transfer to Mammalian Ribosomes : Polyuridylic Acid and (June M. Fessenden and Prof. K. Moldave), 1172
Aminopeptidase Activity in Blood Platelets : Cytochemical Demonstration of (Dr. K. Balogh, jun.), 1196
Amitriptyline : A Fatal Case of Poisoning with (I. Sunshine and J. Bäumler), 1103
Ammonium Cyanide : Formation of Amino-acids, Amino-acid Polymers, Fatty Acids and Purines from (Prof. C. U. Lowe *et al.*), 219
Ammonium Perchlorate : Electrical Conductivity of (P. Zirkind and E. S. Freeman), 1280
Amniotic Fluid : Comparison of Fœtal Pulmonary Fluid with Fœtal Plasma and (B. B. Ross), 1100
Amoore, Dr. J. E. : Action Spectrum of Mitotic Ferrous Complex, 38 ; Stereochemical Theory of Olfaction, 912
Amorphous Tumours Induced in Alfalfa by Potato Leafhoppers (D. K. Barnes and R. C. Newton), 95
Amphetamine and Pentobarbitone on Exploratory Behaviour in Rats : Effects of (Dr. R. Stretch), 787
Amphibian Eggs and *Acetabularia mediterranea* : Effects of Puromycin on Morphogenesis in (J. Brachet), 714
Amphibian Kidney : Purine Catabolism, a Source of Endogenously Formed Urea in Homogenates of (W. A. Brodsky and N. J. Carlisky), 602
Amphibians : Pharmacological Characteristics of Neurohypophysial Hormones in Lungfish and (B. K. Follett and H. Heller), 611
Amphiuma : Karotype and Revised Chromosome Number of (G. M. Donnelly and A. H. Sparrow), 1207
Amplitude and Phase of 16 kc/s Very-low-frequency Signal received in New Zealand : Sudden Changes in (A. H. Allan), 582
Anæmia in Man : Production of Specific Anti-E Autoantibodies in Experimental Iso-immune Hæmolytic (J. F. Mohn *et al.*), 705
Anæsthetic Compound : Benzobutamine, Antitussive Activity of a New Local (G. Maffii *et al.*), 916
L'analyses des silicates (I. A. Voinovitch, J. Debras-Guedon and J. Louvrier), *review* by G. A. Sergeant, 416
Analysis : Official, Standardised and Recommended Methods of (compiled and edited by S. C. Jolly), *review* by Dr. T. S. West, 210
Analysis of Adenovirus Particles and Soluble Antigens produced in the Presence of 5-Bromo-deoxyuridine (L. Kjellén, H. G. Pereira, R. C. Valentine and J. A. Armstrong), 1210
Analysis of Photosynthetic Reactions by the Use of Monochromatic Light (Dr. K. Tagawa, H. Y. Tsujimoto and Prof. D. I. Arnon), 1247
Analysis of Reversibly Interacting Systems of Differential Boundaries in Electrophoretic and Sedimentation Experiments (G. A. Gilbert and R. C. Ll. Jenkins), 688
Analysis of the Life-cycle in Mammalian Cells (W. S. Bullough), 859 ; (V. Defendi and L. A. Manson), 862
Analysis of Tritium-labelled Human Chromosomes and Sex Chromatin (A. Bishop and O. N. Bishop), 930
"Analytical Chemistry in Nuclear Technology", seventh conference on, 962
Anaphylactic Sensitization and Transmission of Passive Immunity : Resemblances between Passive (Prof. F. W. R. Brambell), 1164
Anatomical Meeting : The Second European, September 1963, 232
Anatomy : Dr. M. J. T. Fitzgerald appointed reader in, 1044
Anatomy of Automation (George H. Amber and Paul S. Amber), *review* by Dr. E. M. Deeley, 520
Andersen, P., *et al.* : Identification of Inhibitory Neurones in the Hippocampus, 699 ; Inhibitory Synapses on Somas of Purkinje Cells in the Cerebellum, 655
Andersen, S. B., *et al.* : Intestinal Degradation of Gamma-globulin in the Dog, 1096
Anderson, A. F. H., and Calvin, Prof. M. : Electron Spin Resonance of Crystalline Chlorophyll *A* and Crude Mixtures of Chlorophyll *A* with Normally Associated Pigments, 241
Anderson, C. R., *et al.* : Experimental Transovarial Transmission of Kyasanur Forest Disease Virus in *Haemaphysalis spinigera*, 513
Anderson, D. A., and Freeman, E. S. : Physical Transitions of the Alkali Metal Nitrates as Revealed by Differential Thermal Analysis, 63
Anderson, D. M., and Sposito, G. : Rate of Adsorption of Water Vapour by Degassed Arizone Bentonite, 1085
Anderson, E. C., *et al.* : Cæsium-137 Content of Lambs, 294
Anderson, L., *et al.* : Synthetic Cyclitol Glycoside, 373
Anderson, M. R. : An Attempt to demonstrate *in vivo* Recognition of Ectopically Placed Autologous Tissues, 712
Anderson, Dr. N. G. : Virus Isolation in the Zonal Ultracentrifuge, 1166
Anderson, W., and Soman, P. D. : Degraded Carrageenan and Experimental Acute Gastric Ulceration in the Guinea Pig, 389
Andrews, D. P., *et al.* : Apparent Relative Movement of 'Unsharp' and 'Sharp' Visual Patterns, 161
Andrews, Dr. M. W., and Dr. E. F. Denby : Shrinkproofing Wool, 131
Angerer, L. : Effect of Some Organic Additives on Conduction Current and Breakdown of Insulating Liquids, 62
Angino, E. E., *et al.* : New Isotopic Age Measurements from the McMurdo Sound Area, Antarctica, 685
Angiosperms : Aquatic (K. Subramanyam), *review* by Dr. E. G. Cutter, 523
Angular Size of Radio Stars (V. I. Slish), 682
Anhydrous Complex Cyanide Acids : Infra-red Spectra of some (D. Jones and D. F. Evans), 277
Anhydrous Ruthenium Chlorides (J. M. Fletcher *et al.*), 1089
Animal Cell Strains by Immunofluorescence : Species Identification of (W. F. Simpson and C. S. Stulberg), 616
Animal Ecology : Aims and Methods (A. Macfadyen), second edition, *review* by Prof. G. C. Varley, 313
Animal Health, Vol. 1, No. 1 ; January-March 1963, 121
Animal Species and Evolution (Ernst Mayr), *review* by Sir Julian Huxley, 838
Animal Tissues : Cytochemical Demonstration of Ubiquinones in (J. P. Tranzer and Dr. A. G. E. Pearse), 1063
Animals : Learning and Instinct in (Dr. W. H. Thorpe), second edition, *review* by Prof. F. A. Beach, 313
Anisotropy in Electro-deposited Thin Films : Chemically reduced Nickel Substrates for the Development of Uniaxial (R. D. Fisher and H. E. Haber), 163
Annual Review of Entomology, Vol. 8 (edited by Ray F. Smith), *review* by H. Oldroyd, 108
Annual Review of Microbiology, Vol. 16 (edited by Charles E. Clifton), *review* by Dr. A. Newton, 733
Annual Review of Nuclear Science, Vol. 12 (edited by Emilio Segrè), *review* by Dr. T. E. Cranshaw, 418
Annual Review of Pharmacology. Vol. 2 (edited by Windsor C. Cutting), *review* by Dr. M. J. Rand, 210
Anodic Oxide Films on Aluminium Alloys : Electron-Probe Microanalysis of (Dr. G. C. Wood *et al.*), 239
Anorexic Effect of Intraperitoneal Glucose in the Hypothalamic Hyperphagic Cat (M. Russek and P. J. Morgane), 1004
Anoxia and Cerebral Water Content in the Adult Rat (C. P. Hills and R. G. Spector), 393
Anoxic Perfusion of the Isolated Kidney of a Dog : Production of Erythropoietin by (E. O. Zangheri *et al.*), 572
Anstis, S. M., *et al.* : Influence of Stroboscopic Illumination on the After-effect Seen Movement, 99

Antarctic Earthquakes, A Special Mechanism for some (F. F. Evison and T. Hatherton, *New Zealand Journal of Geology and Geophysics*, 5, No. 5, 1962), 855
Antarctic Expedition : The 1963 Soviet, 959
Antarctic Rocks : Age Measurements of (Queen Maud Land), (P. Pasteels and Sarah Deutsch), 996
Antarctic Sea-Ice : Microbiology of (J. S. Bunt), 1254
Antarctic Snow : Tritium Content of (S. P. Shen *et al.*), 60
Anthocyanins : Effect of Phenolase on (C. Y. Peng and P. Markakis), 597
Anti-E Autoantibodies in Experimental Iso-immune Hæmolytic Anæmia in Man : Production of Specific (J. F. Mohn *et al.*), 705
Antibacterial Activity of Herpes Simplex Virus grown in Tissue Culture (S. S. Schneierson and B. Shore), 721
Antibiotic-like Effect of *Lactobacillus acidophilus* (D. B. Sabine), 811
Antibody, Adsorption of Rabbit, by Rat Tissue Mast Cells and Other Cells *in vitro* (R. Keller and E. Sorkin), 709
Antibody Formation : Persistence of Antigen in Nucleoprotein Fractions of Mouse Spleen Cells during (H. Fiedman), 502
Antibody Response to Soluble Antigen : Duration of (R. V. Gilden and G. L. Rosenquist), 87
Anti-coccidial Activity of Halogenonitrobenzamides (S. J. Ball and E. W. Parnell), 612
Antidepressants and Stimulants : Potentiation of the Anti-reserpine Effects of Dihydroxyphenylalanine by (W. R. McGrath and H. J. Ketteler), 917
Antigen : Duration of Antibody Response to Soluble (R. V. Gilden and G. L. Rosenquist), 87
A New Staphylococcal (M. W. Fisher, H. B. Devlin and A. L. Erlandson), 1074 ; (T. H. Haskell and S. Hanessian), 1075
Antigen–Antibody Precipitates : Demonstration of a Hæmolytically Active 11 S Component of Rabbit, Guinea Pig and Human Serum by means of (J. F. Barbaro), 819
Antigen in Nucleoprotein Fractions of Mouse Spleen Cells during Antibody Formation : Persistence of (H. Friedman), 502
Antigenic Activity of Tryptic Peptides of Tobacco Mosaic Virus Protein (J. D. Young, E. Benjamini, M. Shimizu, C. Y. Leung and B. F. Feingold), 831
Antigens synthesized by *E.coli B/r*s : Effect of 8-Azaguanine on the Specificity of (G. M. Pontieri and O. J. Plescia), 191
Antihæmophilic Globulin in Frozen Plasma (F. Nour-Eldin), 187
Antioxidants in Food : The Detection and Determination of (The Association of Public Analysts), 122
Anti-reserpine Effects of Dihydroxyphenylalanine by Antidepressants and Stimulants : Potentiation of the (W. R. McGrath and H. J. Ketteler), 917
Antiserum Specific to a Spontaneous Mouse Leukæmia after the Induction of Artificial Immunological Tolerance to Normal Mouse Tissue : Preparation of an (E. Levi), 501
Anti-sulphonamide and Streptomycin Effect : A New Metabolic Regulator : its Stimulation of Citric Acid Production and (Dr. Z. Fencl and E. Vintrová), 905
Antitussive Activity of a New Local Anæsthetic Compound : Benzobutamine (G. Maffii, B. Silvestrini and S. Banfi), 916
Anxiety on Real and Ideal Vocational Aspiration among Grammar School Boys : Effect of (L. W. Littig), 1214
Aomine S., and Miyauchi, N. : Age of the Youngest Hydrated Halloysite in Kyushu, 1311
Aortic Wall as a 'Two-phase' Material (S. Glagov and H. Wolinsky), 606
Apartheid and the South African Library Association, 746
Apicultural Research (M. Delia Allen), 651
Apicultural Research, Journal of, Vol. 1, 651
Apis mellifera L. : Drone Production in Honey-bee Colonies (Dr. M. D. Allen), 789
Aplodontia rufa and the Rabbit : Influence of Diet on Urine Concentration in (E. W. House *et al.*), 181
Aplysia depilans L. : Presence of Ribonucleic Acid in the Initial Yolk Globules of Oocytes of (A. Bolognari and A. Donato), 697
Apparatus Drawings Project (30 Drawings), *review* by Dr. A. R. Meetham, 414
Apparatus for the Automatic Location of Absorbing Components separated by Density Gradient Centrifugation (J. G. Edwards and A. P. Mathias), 603
Apparent Relative Movement of 'Unsharp' and 'Sharp' Visual Patterns (F. J. Verheijen), 160 ; (D. P. Andrews, D. M. MacKay and J. P. Wilson), 161
Appearance of Slow α_2-Globulin after Interference with the Liver (W. G. Heim and J. M. Kerrigan), 1100
Apples : Effect of Time of Picking on the Ethylene Production of (B. G. Wilkinson), 715
Application of Atomic Absorption Spectroscopy to the Determination of Cobalt in Steel, Alloy Steel and Nickel (G. L. McPherson, J. W. Price and P. H. Scaife), 371
Application of the Arrhenius Equation to Rat Tail Tendon Collagen (W. H. Akeson), 185
Applied Dynamic Programming (Richard E. Bellman and Stuart E. Dreyfus), *review* by J. J. Florentin, 6
Approaches to Atomic Physics, 1122
Aquatic Angiosperms (K. Subramanyam), *review* by Dr. E. G. Cutter, 523
Aqueous Media : Behaviour of Polarons produced by the Action of Ionizing Radiation in (J. J. Weiss), 589
Aqueous Reprocessing Chemistry for Irradiated Fuels, Symposium held, 542.
Aqueous Solution : Radiation Yield of Citraconic and Mesaconic Acids in (A. L. Fantola *et al.*), 594
Aqueous Solutions irradiated with γ-rays in the Presence of Oxygen : Nature and Reactions of the Reducing Species in (G. Scholes and M. Simic), 276
Arabian Sea : Geology and Geochronology of the Seychelles Islands and Structure of the Floor of the (B. H. Baker and Dr. J. A. Miller), 346
Arcella : Oxygen in the Gas Vacuole of the Rhizopod Protozoan (Anna Cicak *et al.*), 983
Archæology : Matrix Analysis and (D. L. Clarke), 790 ; (J. Matthews), 792
Metallurgy in (Dr. R. F. Tylecote), *review* by Prof. F. C. Thompson, 1223
Archangelsky, S. : A New Mesozoic Flora from Tico, Santa Cruz Province, Argentina (*Bulletin of the British Museum (Natural History) : Geology*, 8, No. 2, *review* by T. M. Harris, 418
Argentaffinoma ? Pinealoma : a Variety of (I. Costero *et al.*), 190
Arginine-Vasopressin : Carbamylation of Oxytocin and (G. W. Bisset *et al.*), 69
Argon and Methane : Temperature of Shocked (C. E. Reynolds and L. B. Seely), 341
Argon Carrier Gas : Total Trapping of Chromatographic Effluents in (Dr. P. A. T. Swoboda), 31
Argon Content of Tektites : Radiogenic and Atmospheric (J. Zähringer and W. Gentner), 583
Argon, Retention of Radiogenic : in Glauconites from Proterozoic Sediments, Northern Territory, Australia (A. W. Webb, I. McDougall and J. A. Cooper), 270
Arithmetical Facts : Sources of Difficulty in Learning (H. B. G. Thomas), 99
Arley, N., and Niskanen, E. E. : A Stochastic Model of Carcinogenesis compared with Mouse Skin Tumour Enhancement after Gastric Instillation of 9,10-Dimethyl-1,2-Benzanthracene with Subsequent Local Continuous Explosure to 'Tween 40', 83
Armstrong, J. A., *et al.* : An Analysis of Adenovirus Particles and Soluble Antigens produced in the Presence of 5-Bromo-deoxyuridine, 1210
Arnason, B. G., *et al.* : Immunoglobulin Abnormalities of the Thymectomized Rat, 1199
Arnold, Dr. G. : *Obituary* by Dr. E. Pinhey, 429
Arnon, Prof. D. I., *et al.* : Analysis of Photosynthetic Reactions by the Use of Monochromatic Light, 1247
Aromatic Acids of Fermented Cacao (V. C. Quesnel and J. B. Roberts), 605
Aromatic Amines : Carcinogenic and Chronic Toxic Hazards of (T. S. Scott), *review* by Prof. E. Boyland, 1026
Aromatic Ring in Insects : Synthesis of an (P. C. J. Brunet), 492
Arrhenius Equation to Rat Tail Tendon Collagen : Application of the (W. H. Akeson), 185
Art Gallery of the Western Australian Museum, Annual Reports for 1960-61, 962 ; 1961-62, 962
Arteries of the Muscular Type : Effect of Different Vasomotor Agents on the Vasco-elastic Behaviour of (H. Kulbertus), 1193
Artman, M., and Bekierkunst, A. : Effect of *Mycobacterium tuberculosis H37Rv* grown *in vivo* (*LH37Rv*) on Ehrlich Carcinoma Ascites Cells, 1308
Arulpragasam, P. V., *et al.* : Oil Spot Disease in Tea, 92
Ascites Tumours : Infiltration of Intra-abdominal Organs by (D. N. Wheatley *et al.*), 188
Ascospores of *Endomycopsis selenospora* (N. J. W. Kreger-van Rij and J. P. van der Walt), 1012
Ashby, Sir Eric : Community of Universities, *review* by Sir James Mountford, 838
Investment in Man, 877
Asia and Oceania Congress of Endocrinology (I. G. Jarrett), 858
Aspidin : The Precursor of Bone (Dr. L. B. H. Tarlo), 46
Associated Electrical Industries Levitron (Dr. N. L. Allen *et al.*), 123
Association for Science Education : *Science in Sixth-form General Education*, 853
Association of Consulting Scientists : Election of Officers, 23
Association of Public Analysts : *The Detection and Determination of Antioxidants in Food*, 122
Association of Universities of the British Commonwealth 1913-1963 : Community of Universities (Sir Eric Ashby), *review* by Sir James Mountford, 838
Assynt Dykes and their Metamorphism (J. Tarney), 672
Astringency of Persimmons (*Diospyros kaki*, L.) (T. O. M. Nakayama and C. O. Chichester), 73
Astrometric Reflector : U.S. Naval Observatory, 1041
Astronautical Congress, The fourteenth International, 645
Astronautical Propulsion : Advances in, Proceedings of a Seminar held in Milan by Instituto Lombardo Accademia di Scienze e Lettere in collaboration with the Advisory Group for Aeronautical Research and Development of Nato, 1960 (edited by Corrando Casci), *review* by D. G. King-Hele, 525
Astronomer : The Sun and the Amateur (W. M. Baxter), *review* by J. Heywood, 840
Astronomical Clock Tower : A Working Model of the Mechanical Escapement in Su Sung's (Prof. A. F. Burstall *et al.*), 1242
Astronomy : Accurate Time for Field (W. A. Stepec), 135
Atiyah, Prof. M. F. : Appointed to the Savilian professorship, 120
Atkinson, E. P., and Tuey, G. A. P. : *In situ* treatment of Kieselguhr for Gas Chromatography, 482
Atmosphere (60-140 km) by Optical Radar : Detection of Scattering Layers in the Upper (G. Fiocco and L. D. Smullin), 1275
Atmospheric Hydrogen Sulphide Concentrations During the London Fog of December 1962 (J. T. Minster), 474
Atmospheric Ozone : A New Instrument for (D. I. Wardle *et al.*), 1177
Atmospherics at 27 kc/s : Solar Flux Fluctuations at 225 Mc/s and Noise-level of (F. G. Drago *et al.*), 363
Atom : Rutherford and the, Poetic Portrayal of a Scientific Discovery (Prof. John Francis), 1028
Atom, June and July 1963, 746
Atomic Absorption Spectroscopy : Determination of Gold and of Silver in Solution by (M. C. Greaves), 552
Atomic Absorption Spectroscopy to the Determination of Cobalt in Steel, Alloy Steel and Nickel : Application of (G. L. McPherson *et al.*), 371
Atomic Energy Review, 645
Atomic Hydrogen in γ-irradiated Ice : Formation of Electrons and of (L. Kevan *et al.*), 689
Atomic Physics : Approaches to, 1122
Atomic Spectroscopy : Operator Techniques in (Prof. Brian R. Judd), *review* by Prof. K. W. H. Stevens, 1222
Atomic Structure : Constant Energy Differences in (E. C. Baughan), 169
Atomic Theory and the Description of Nature : Four Essays, with an Introductory Survey (Prof. Niels Bohr), first printed 1934, *review* by Dr. E. Bretscher, 317
Auerbach, Dr. C. : Effects of Atomic Radiation (198, 343), 539
Aurora : Photometric Observations of the (Dr. S. M. Silverman, 198, 678), *erratum*, 24
Austin, C. M., *et al.* : Behaviour of Active Bacterial Antigens during the Induction of the Immune Response, 1259
Australian Atomic Energy Commission, 544
Australian Defence Standards Laboratories (S. Weintroub), 965
Australian Journal of Soil Research, 1, No. 1, 1963, 1139
Australian Marine Sciences Association : Inaugural Meeting and Election of Council, 332
Australian National University : Appointment, 536
Autoclave caused by Cellulose Nitrate Tubes : Explosion in an (I. H. Silver), 102
Autologous Tissues : An Attempt to demonstrate *in vivo* Recognition of Ectopically Placed (M. R. Anderson), 712
"Automated Chemical Analysis and Automated Analytical Techniques", annual symposium by Technicon Instruments Company, 1238
Automatic Control (A. E. De Barr), *review* by Dr. E. M. Deeley, 520
Automatic Control Handbook (Advisory Editor G. A. T. Burdett), *review* by Dr. E. M. Deeley, 520
Automation : Anatomy of (George H. Amber and Paul S. Amber), *review* by Dr. E. M. Deeley, 520
Autoradiographic Investigation with Microdensitometry : Differences in the Utilization of Tritiated Leucine by Single Neurones in Normal and Exercised Rats : An (Dr. J. Altman), 777
Autoradiographs : Another Variable to be observed in (R. T. Sims), 395
Autoradiography of Chemically Reactive Surfaces : High Resolution (G. T. Rogers and J. D. H. Hughes), 566
Autosome 16 : Trisomy of (F. J. W. Lewis *et al.*), 404
Autoxidation : Some Unusual Observations in a Comparison of Liquid and Solid Phase (A. T. Betts and Dr. N. Uri), 568
Auxins and Auxin Esters on the Survival of Free Cells of the Ehrlich Ascites Carcinoma : Effects of Plant Growth Regulators (Dr. R. D. Schultz and Dr. D. Norman), 260
Avakian, S., *et al.* : Absorption of Chymotrypsin from the Intestinal Tract, 815
Avena : Diploid-like Pairing in a Synthetic Decaploid (H. Thomas), 1209

Avena sativa : Hydroxylation of Phenoxyacetic Acid by Stem Tissue of (E. W. Thomas *et al.*), 73
Avian Liver : Thin-layer Chromatographic Separation and Quantitative Determination of Several Free Amino-Acids of (R. L. Squibb), 1216
Avivi, P., *et al.* : Slow Expansion of a Plasma Column without the Application of a Magnetic Field, 1244
Axelrad, A. A. : Changes in Resistance to the Proliferation of Isotransplanted Gross Virus-induced Lymphoma Cells, as measured with a Spleen Colony Assay, 80
Axelsen, A., *et al.* : Effects of Œstrogen on Fertility in Ewes, 403
Axon, Dr. H. J. : Progress in Materials Science, Vol. 9, *review*, 414
Axonal Reaction of the Nerve Cell : Changes of Coenzyme (TPN) Diaphorase and TPN-linked Dehydrogenase during (G. W. Kreutzberg), 393
Axons of Squid : Micro-injection of Trypsin into (E. Rojas and M. Luxoro), 78
Aymestry Limestone of Shropshire : Occurrence of *Kockelella variabilis* Walliser in the (F. H. T. Rhodes and G. Newall), 166
Ayre, G. L. : Response to Movement by *Formica polyctena* Forst, 405
8-Azaguanine on the Specificity of Antigens synthesized by *E.coli B/r*₂ : Effect of (G. M. Pontieri and O. J. Plescia), 191
Azo Dyes : Adsorption Chromatography of Direct (P. Raban), 596

BACILLUS Calmette-Guérin Infection on the Intensity of Homograft Reaction in Rats : Influence of (R. Vitale and N. Allegretti), 507
Bacillus subtilis Cells of Reproducible Competency : Overnight Incubation Technique for obtaining Transformable (D. Bobb), 828
Backhouse, J. K. : The Mathematical Association Annual Conference, 27
Back-scatter of Radio Waves from the Equatorial *F* Region (B. R. Clemesha), 797
Bacteria : Effect of Diurnal Freeze-Thawing on Survival and Growth of Selected (R. S. Young *et al.*), 1078
Membrane Stability and Salt Tolerance in Gram-negative (A. D. Brown and H. P. Turner), 301
Resistance to Copper of some Oxidizing and Reducing (G. H. Booth and S. J. Mercer), 622
Bacteria, The, a Treatise on Structure and Function (edited by I. C. Gunsalus and Roger Y. Stanier), Vol. 3, *review* by Dr. L. B. Quesnel, 4
Bacterial Antigens during the Induction of the Immune Response : Behaviour of Active (G. L. Ada *et al.*), 1257 ; (G. J. V. Nossal *et al.*), 1259
Bacterial Cultures : Single-cell Isolation and Preservation of (Prof. J. E. DeVay and W. C. Schnathorst), 775
Bacterial Flagellation : Trace Metal Control of (E. D. Weinberg and J. I. Brooks), 717
Bacterial Mutants in the Replica Plating Technique : A Photographic Method for the Detection of Rare (J. H. van de Pol *et al.*), 198
Bacterial Wall and Cell Contents : Partition of Divalent Cations between (Prof. J. M. Vincent and Beverley A. Humphrey), 149
Bacteriochlorophyll by *Rhodopseudomonas spheroides* : Influence of Light on the Biosynthesis of (G. Drews and K. Jaeger), 1112
Bacteriology : Dr. J. M. Dunbar appointed lecturer in, 434
Bacteriophages : Host-range of *Proteus morganii* (J. N. Coetzee), 827
Baden-Powell, D. F. W. : Isostatic Recovery in Scotland, 546, 1278
Bailey, R. W. : Maltose in Red Clover (*Trifolium pratense*) Leaves, 1291
Bailey, R. W., and Clarke, R. T. J. : Carbohydrases of the Rumen Oligotrich *Eremoplastron bovis*, 1291
Bailey, Prof. V. A. : The Interplanetary Magnetic Field, 1029
Baines, Dr. H. : *Obituary*, 21
Baker, B. H., and Miller, Dr. J. A. : Geology and Geochronology of the Seychelles Islands and Structure of the Floor of the Arabian Sea, 346
Baker, E. A., and Martin, Dr. J. T. : Cutin of Plant Cuticles, 1268
Bakhle, Y. S., *et al.* : Incorporation of 5-Iodo-2′-deoxyuridine into the Deoxyribonucleic Acid of Vaccina Virus, 1310
Balachowsky, Prof. A. S., Traité publié sous la direction de : Entomologie Appliquée à l'Agriculture, Vols. 1 and 2, *review* by Dr. K. Mellanby, 842
Balaenoptera borealis Lesson : Functional Polyovuly in the Sei Whale (P. B. Best and J. L. Bannister), 89
Balasubramaniam, S., *et al.* : Transpiration Phenomena in Detached Leaves, 265
Baldwin, R. W., *et al.* : Carcinogenic Action of *N*-hydroxy-4-acetylaminostilbene, 613
Baldwin, W. F., *et al.* : Effects of X-rays on Electrical Activity in the Eye of the Cockroach *Blaberus giganteus*, 616
Balfour, Dr. D., *et al.* : The Associated Electrical Industries Levitron, 123
Balinsky, Doris and Bernstein, R. E. : Oxidation of Reduced Glutathione by Acetylphenylhydrazine, Hæmoglobin and Erythrocytes, 187
Ball, Prof. J. G., *et al.* : Education in Materials Science, 233
Ball, J. N., *et al.* : Secretion of Thyrotrophic Hormone by Pituitary Transplants in a Teleost Fish, 618
Ball, S. J., and Parnell, E. W. : Anti-coccidial Activity of Halogenonitrobenzamides, 612
Ball Lightning (E. R. Wooding), 272
Balogh, jun., Dr. K. : Cytochemical Demonstration of Aminopeptidase Activity in Blood Platelets, 1196
Banfi, S., *et al.* : Antitussive Activity of a New Local Anæsthetic Compound : Benzobutamine, 916
Bannister, J. L., and Best, P. B. : Functional Polyovuly in the Sei Whale *Balaenoptera borealis* Lesson, 89
Bárány, K., *et al.* : Effect of Ultrasonics on the Adenosine Triphosphatase Activity and Actin-binding Ability of L-Myosin and Heavy Meromyosin, 694
Bárány, M., *et al.* : Effect of Ultrasonics on the Adenosine Triphosphatase Activity and Actin-binding Ability of L-Myosin and Heavy Meromyosin, 694
Barbaro, J. F. : Demonstration of a Hæmolytically Active 11 *S* Component of Rabbit, Guinea Pig and Human Serum by means of Antigen-Antibody Precipitates, 819
Barber, Prof. H. N. : Appointed to the chair of Botany, 643
Barbiturates in Blood in Emergency Cases : Quantitative Estimation and Identification of (Dr. H. V. Street and C. McMartin), 456
Barbiturates (Pseudo) in Post-mortem Material : Occurrence of (J. V. Jackson and B. S. Finkle), 1061
Barbu, Dr. Z. : Appointed lecturer in Social Studies, 1044
Barium Content of Different Parts of the Choroid of the Bovine Eye (K. Kostial-Simonovic and A. Pirie), 1007
Barker, S. A., *et al.* : Characterization of the Products of the Action of Bee Venom Hyaluronidase, 693
Barker, W. G., and Lawrence, C. H. : Pathogenicity of *Streptomyces scabies* on Potato Tubers cultured *in vitro*, 509
Barkley, W. K., and Gunning, Dr. B. E. S. : Kinin-induced Directed Transport and Senescence in Detached Oat Leaves, 262
Barley : Male Sterility for Increased Outbreeding in Populations of (S. K. Jain and C. A. Suneson), 407
Barley Endosperm Bioassay for Gibberellins (P. B. Nicholls and L. G. Paleg), 823
Barley with Ultra-violet Radiation : Induction of Mutations in (A. T. Natarajan and S. Nirula), 822
Barltrop, Dr. J. A., *et al.* : Mechanisms for Oxidative Phosphorylation at the Pyridine Nucleotide/Flavoprotein Level, 759
Barnes, D. E., *et al.* (Advisory Editors) : Newnes Concise Encyclopædia of Nuclear Energy, *review* by Dr. J. Thewlis, 1025
Barnes, D. K., and Newton, R. C. : Amorphous Tumours induced in Alfalfa by Potato Leafhoppers, 95
Barnett, S. A. : A Study in Behaviour : Principles of Ethology and Behavioural Physiology, Displayed mainly in the Rat, *review* by Dr. W. H. Thorpe, 943
Bar-Or, A., *et al.* : Growth and Nucleation of the $\beta \rightarrow \alpha$ Transformation in Uranium 0.45 per cent Chromium Alloy, 585
Barr, G. C., and Butler, Prof. J. A. V. : Histones and Gene Function, 1170
Barrer, R. M., and Coen, P. J. : Dielectric Loss and Hydration of Sodium Chabazite, 587
Barrett, J. F., and Ryan, A. J. : Thin-layer Chromatography of Some Food Colours on Silica Gel, 372
Barroso-Moguel, R., *et al.* : Pinealoma : a Variety of Argentaffinoma ? 190
Barry, B. E., and Bolger, D. E. : Preparation of Aluminium Arsenide by a Vapour Phase Transport Reaction, 1287
Bartley, Dr. W. : Appointed to the chair of Biochemistry, 232, 331
Basalts : Implications of Similarity in Rare-earth Fractionation of Nakhlitic Meteorites and Terrestrial (Dr. R. A. Schmitt and R. H. Smith), 550
Basic Concepts of Measurement and the Michelson-Morley Experiment (L. Essen), 684
Bat : Biomicroscopic Observations on Vasoconstrictive and Thrombogenic Effects produced by Long-chain Saturated Fatty Acids within the Vasculature of the Wing of an Unanæsthetized (L. A. Soloff and M. P. Wiedman), 495
Battelle Memorial Institute : International Symposium to be held, 645 ; *A Practical Plan for the Effective Use of Outside Research Facilities*, 1237
Baughan, E. C. : Constant Energy Differences in Atomic Structure, 169

Cæsium–Choline Interaction on Muscle Membrane (A. Portela, J. C. Perez and P. Stewart), 815
Cæsium-137 Content of Lambs (A. H. Kirton, A. M. Pearson and E. C. Anderson), 294
Cæsium-137 in Air and Precipitation in Norway during October 1957 (T. Hvinden and A. Lillegraven), 366
Calabresi, P., and Rosenberg, S. : Enhanced Suppression of the Secondary Immune Response by Combination of 6-Mercaptopurine 'Duazomycin A', 1101
Calcification in the Intervertebral Disk (T. K. F. Taylor and K. Little), 612
Calcium and Strontium by Brown Trout in Waters in the United Kingdom : The Accumulation of (W. L. Templeton and V. M. Brown), 198, 199, *erratum*, 122
Calcium Compounds on the Survival of X-irradiated Rats : Effect of Multiple Injections of (R. H. Rixon and J. F. Whitfield), 821
Calcium Deficiency : Mechanism of the Antagonism by Tetraethylammonium of Neuromuscular Block due to *d*-Tubocurarine or (B. Collier and K. A. Exley), 702
Calcium-Dependent Contractions with Hydrogen Bond Formation Plus ATP-Dependent Extensions of Part of the Myosin-Actin Cross-Bridges (Prof. R. E. Davies), 1068
Calcium in Parotid Saliva of Sheep : Secretion of Magnesium and (A. D. Care), 818
Calcium-ITP-Contraction of Glycerol-Extracted Muscle : Partial Reversibility of the (W. Kuhn et *al.*), 1154
Calcium Phosphate on the Absorption of Radioactive Strontium : Influence of (R. S. Bruce), 1107
Calculation of Valence State Energies from Thermochemical Data (B. Siegel and S. Siegel), 591
Caldwell, K. A., et *al.* : Synthetic Cyclitol Glycoside, 373
Caledonian Origin : Norwegian Minerals and Rocks of Possible (I. Hernes), 686
Calf Muscles of Normal Human Subjects : Tonic Stretch Reflexes in the (R. F. Mark), 50

Cali, J. P., *et al.* : Non-destructive Radioanalytical Method for the Determination of Gallium in Substituted Yttrium Iron Garnets, 1081
Callow, W. J. : British Standard of Radioactive Iodine-131, 898
Calne, R. Y. : Thymectomy in Dogs with Renal Homografts treated with Drugs, 388
Calorimetry Conference, The Eighteenth, 1044
Calvin, Prof. M. : Elected foreign member, The Royal Society, Edinburgh, 119
Calvin, Prof. M., and Anderson, A. F. H. : Electron Spin Resonance of Crystalline Chlorophyll *A* and Crude Mixtures of Chlorophyll *A* with Normally Associated Pigments, 241
Campaign for Education : *Finance of Education*, 1137
Campana, H., *et al.* : Production of Erythropoietin by Anoxic Perfusion of the Isolated Kidney of a Dog, 572
Campbell, D., *et al.* : Electron Spin Resonance in Polymer Carbons : Effect of Halogens and Interhalogen Compounds, 1090
Canadian Arctic Geology, 1043
Canadian Biochemical Society : Election of Officers, 435
Cancer Cells in Culture by *Bis*(Thioinosine)-5′, 5‴-Phosphate : Inhibition of 6-Mercaptopurine-resistant (J. A. Montgomery *et al.*), 769
Canterbury, The Archbishop, *et al.* : *The Case for Advance*, 628
Capacitation of Ram Spermatozoa and Penetration of the Ovine Egg (P. E. Mattner), 772
Capillary Blood Vessels in the Central Nervous System of the Rabbit : Acetylcholinesterase Activity of (Lt. Col. J. C. Crook), 41
Capillary Permeability of Extract of Various Parts of Human Brain : Substance *P* Content and Effect on (F. Lembeck and K. Starke), 1295
Capillary Plexuses in Gastropods stained by the Novikoff Reaction for Thiamine Pyrophosphatase (O. L. Thomas), 89
Capraro, V., *et al.* : Influence of 2,4-Dinitrophenol on Anion Transport by an Intestinal *in vitro* Preparation, 1099
Capsella : Intermittent Germination of (Sir Edward Salisbury), 1303
Carbamylation of Oxytocin and Arginine-Vasopressin (G. W. Bisset, A. M. Poisner and D. G. Smyth), 69
Carbide : Polymorphism in Silicon (E. Dow Whitney), 278
Carbohydrases of the Rumen Oligotrich *Eremoplastron bovis* (R. W. Bailey and R. T. J. Clarke), 1291
Carbohydrate Chemistry : Advances in, Vol. 17 (edited by Melville L. Wolfrom), *review* by Dr. W. J. Whelan, 1124
Carbon-14 : Stability of Thymidine Labelled with Tritium or (Dr. E. A. Evans and F. G. Stanford), 762
Carbon-14 in Plant Material by Wafter Counting : Determination of (J. R. Corbett and C. S. Miller), 1106
Carbon-14 into Susceptible and Pyrethroid Resistant Houseflies : Penetration of Pyrethrin I labelled with (B. C. Fine *et al.*), 927
Carbon Dioxide : A Factor Influencing Cell Division (Dr. C. L. Mer and D. R. Causton), 360
Carbon Dioxide on Evaporation of Water : Effect of (F. Sechrist), 899
Carbon Dioxide on the Rabbit During Surface Cooling down to Cardiac Arrest : Effects of Air, Oxygen and 20 per cent (Dr. B. Broom), 1155
Carbon Disulphide : Formation and Properties of the Black Form of (E. G. Butcher *et al.*), 756
Carbon Electrode Emerging from an Electrolyte : Reduction of Oxygen at a (S. R. Faris), 754
Carbon Monoxide : Adsorption of Krypton and Xenon on Evaporated Metal Films in Relation to the Determination of Surface Area and the Nature of Adsorbed (D. Brennan *et al.*), 1152
Carbonatites : Experimental Data bearing on the Role of Liquid Immiscibility in the Genesis of (A. F. Koster van Groos and P. J. Wyllie), 801
Carbonic Anhydrase and Formation of the Hen's Egg Shell (D. S. Robinson and N. R. King), 497
Carcinogenesis compared with Mouse Skin Tumour Enhancement after Gastric Instillation of 9,10-Dimethyl-1,2-Benzanthracene with Subsequent Local Continuous Exposure to 'Tween 40' : A Stochastic Model of (E. E. Niskanen and N. Arley), 83
Carcinogenic Action of *N*-hydroxy-4-acetylaminostilbene (R. W. Baldwin, W. R. D. Smith and S. J. Surtees), 613
Carcinogenic Activity of Organic Molecules : Electron-donor or Electron-acceptor Properties and (B. Pullman and A. Pullman), 467 ; (A. C. Allison and T. Nash), 469
Carcinogenic and Chronic Toxic Hazards of Aromatic Amines (T. S. Scott), *review* by Prof. E. Boyland, 1026
Carcinoma : Effects of Plant Growth Regulators (Auxins and Auxin Esters) on the Survival of Free Cells of the Ehrlich Ascites (Dr. R. D. Schutlz and Dr. D. Norman), 260
Carcinogenicity of Preheated Fats (R. S. d. Zaldívar), 1300
Carcinostatic Compound Proliferated by a Thermophilic Actinomycete : 'Refuin' : a Non-cytotoxic (M. D. Tendler and S. Korman), 501
Cardiac Arrest : Effects of Air, Oxygen and 20 per cent Carbon Dioxide on the Rabbit during Surface Cooling Down to (Dr. B. Broom), 1155
Cardio-vascular Diseases : Blood Rheology in (L. Dintenfass), 813
Cardozo, R. L., and Dejonghe, P. : Decontamination of Synthetic Effluent by Flotation, 687
Care, A. D. : Secretion of Magnesium and Calcium in Parotid Saliva of Sheep, 818
Carlisky, N. J., and Brodsky, W. A. : Purine Catabolism, a Source of Endogenously Formed Urea in Homogenates of Amphibian Kidney, 602
Carlisle, S. S. : Appointed director of the British Scientific Instrument Research Association, 745
Carmichael, Prof. C. M. : A Magnetized Artificial Meteorite, 426
Carnegie Institution : Brochure on the Observatories and Geophysical Laboratory, 333
Transfer of two laboratories, 120
Caro, Prof. D. E., *et al.* : Modern Physics : An Introduction to Atomic and Nuclear Physics, *review* by K. E. B. Jay, 6
Carpenter, L. G., *et al.* : Measurement of Thermal Accommodation of Gases on Heated Solids, 164
Carr, A. J., and Hendry, N. G. C. : Glycosidase Abnormality in Synovial Membrane in Joint Disease, 392
Carr, T. D., *et al.* : Occultation Theory of Jovian Radio Outbursts, 167
Carrageenan, Degraded, and Experimental Acute Gastric Ulceration in the Guinea Pig (W. Anderson and P. D. Soman), 389
Carte des Sols et de la Vegetation du Congo, du Rwanda et du Burundi, 1043
Carter, L. J. (edited by) : Communications Satellites : Proceedings of a Symposium, London, 1961, *review* by T. W. G. Dawson, 939
Cartwright, B., and Brown, Dr. F. : Purification of Radioactive Foot-and-Mouth Disease Virus, 1168
Casci, Corrado (edited by) : Advances in Astronautical Propulsion : Proceedings of a Seminar held in Milan by Instituto Lombardo Accademia di Scienze e Lettere in collaboration with the Advisory Group for Aeronautical Research and Development of Nato, 1960, *review* by D. G. King-Hele, 525
Case for Advance (Archbishop of Canterbury *et al.*), 628
Case of Somatic Polyploidy (H. Wallace), 1115
Caskey, jun., J. E., and Wexler, H. (edited by) : Meteorology : Proceedings of the First International Symposium on Rocket and Satellite, 1962, *review* by Dr. R. Firth, 729
Caspersson, Dr. O., and Révész, L. : Cytochemical Measurement of Protein Sulphydryls in Cell Lines of Different Radiosensitivity, 153
Cass, Sir John, College, London : Courses for 1963-64, 855
Cat : Anorexic Effect of Intraperitoneal Glucose in the Hypothalamic Hyperphagic (M. Russek and P. J. Morgane), 1004
Functional Coupling between Cells in the Visual Cortex of the Unrestrained (J. S. Griffith and G. Horn), 876
Cat Serum : Localization and Fractional Determination of Neutral Deoxyribonuclease Activity in (G. Riou and C. Paoletti), 697
Catalase and Peroxidase in the Metabolism of Leucocytes : Role of (M. Rechcigl, jun., and W. H. Evans), 1001
Catalysis : Dislocations and (J. W. Hall and H. F. Rase), 585
Catalysis and Related Subjects : Advances in, Vol. 13 (edited by D. D. Eley, P. W. Selwood and Paul B. Weisz), *review* by D. A. Dowden, 727
Cataract in Frogs : Two Components in the Development of Ray (V. V. Popov *et al.*), 1109
Catchside, Prof. D. G. : Appointed to the chair of Genetics, 536
Catling, W. S., and Hayes, J. D. : Physiological Specialization in *Erysiphe graminis* DC. in Oats, 1111
Cattle : Blood typing of Indian Water Buffaloes with Reagents for Antigenic Factors of (S. P. Datta and W. H. Stone), 1208
A Blood typing Service for, 644
Cattle Transferrins and Blood Groups : Tests for Linkage of the Genes controlling (S. P. Datta and W. H. Stone), 1209
Causton, D. R., and Mer, Dr. C. L. : Carbon Dioxide : A Factor Influencing Cell Division, 360
Cedar, Eastern Red (*Juniperis virginiana* L.) : Stimulation by Citric Acid of Germination of (C. Cotrufo), 92
Celery Seedlings by Viable Spores of *Septora* spp. : Infection of (J. E. Sheridan), 508
Cell Contents : Partition of Divalent Cations between Bacterial Wall and (Prof. J. M. Vincent and Beverley A. Humphrey), 149
Cell Culture : Skin Biopsy for (R. G. Davidson *et al.*), 296
Cell Division : Carbon Dioxide : A Factor Influencing (Dr. C. L. Mer and D. R. Causton), 360
Cell Lines of Different Radiosensitivity : Cytochemical Measurement of Protein Sulphydryls in (Dr. O. Caspersson and L. Révész), 153
Cell Mitosis : Effect of Electrostatic Fields on (L. Bozóky *et al.*), 1306
Cell Reactions : Integration of (Dr. A. C. R. Dean and Sir Cyril Hinshelwood), 7
Cells : Differences in the Disposition of Endogenous and Exogenous Substances by (A. V. Furano and J. P. Green), 380
Cells in the Visual Cortex of the Unrestrained Cat : Functional Coupling Between (J. S. Griffith and G. Horn), 876
Cells which retain Activity after Freeze-drying : Homograft Antigens : Isolation of Fractions of Normal (L. T. Mann, jun., *et al.*), 499
"Cellular Control Mechanisms and Cancer" conference on, 435
Cellular Potassium ? Muscle Biopsy in Man : An Index of (Dr. C. T. G. Flear and Irené Florence), 156
Cellular Uptake of Chloramphenicol as revealed by Fluorescence Microscopy (L. Diamond), 90
Cellulose Nitrate Tubes : Explosion in an Autoclave caused by (I. H. Silver), 102
Cellulose occurring in Preserved Cabbage Tissue : A Non-enzymatic Oxidative Degradation of (J. C. Dakin), 383
Cement and Concrete Association : New Materials Testing Laboratory (H. B. Milner), 546
Cement, Portland : Importance of Mixing Sequence when using Set-retarding Agents with (G. M. Bruere), 32
Cements : Evidence for New Phase occurring in Portland (A. E. Moore), 480
Centifanto, Y. M., *et al.* : Nitrogen Fixation by the Leaf-nodule Endophyte of *Psychotria bacteriophila*, 396
Central Food Technological Research Institute, Mysore, Annual Report 1961-62, 651
Central Nervous Control of the Mechanical Properties of the Cuticle in *Rhodnius prolixus* (J. A. Nunez), 621
Central Nervous System : Minute Structure of the Inner Surface of an Embryonic (R. Jelínek and E. Klika), 394
Central Nervous System Disease after Intracutaneous Administration of Myelin Preparations derived from Human Brain : Skin Reaction in Children and Adults with (D. Böhme *et al.*), 84
Central Nervous System of the Rabbit : Acetylcholinesterase Activity of Capillary Blood Vessels in the (Lt. Col. J. C. Crook), 41
Central Organization for Defence (Cmnd. 2097), 1021
Centralizing Britain's Defence Organization, 1021
Centre National de la Recherche Scientifique, Colloques Internationaux du, No. 104, Paris 1961, *review* by Dr. R. J. G. Savage, 107
Rapport d'Activité, 1961/62, 959
Centrifugal Fibres in the Lateral Olfactory Tract (T. P. S. Powell and W. M. Cowan), 1296
Cephalosporin *C.* : Microbial Degradation of (A. L. Demain *et al.*), 909
Cephalosporinase by *Pseudomonas pyocyanea* : Production of a (M. Jago *et al.*), 375
Cerebellum : Inhibitory Synapses on Somas of Purkinje Cells in the (Dr. P. Andersen *et al.*), 655
Cerebral Localization of Psychological Function (Prof. O. L. Zangwill), 887
Cerebral Microsomal Adenosine-triphosphatase : Phosphoprotein as an Intermediate in (S. P. R. Rose), 375
Cerebral Water Content in the Adult Rat : Anoxia and (C. P. Hills and R. G. Spector), 393
Čermák, V., and Herman, Z. : Mass Spectrometric Investigation of Reactions of Electronically Excited Neutral Particles with Alkali Metal Atoms, 588
Cervoni, P., *et al.* : Medullary Vagal Effects of *d*-Lysergic Acid Diethylamide in the Decerebrate Cat, 700
Chain Structure of the *Cyclo*pentadienils of Monovalent Indium and Thallium (E. Frasson, F. Menegus and C. Panattoni), 1087
Chalk Lime and Allied Industries Research Association Open Days, 1044
Chalmers, Dr. Buce (edited by) : Progress in Materials Science, Vol. 9, *review* by Dr. H. J. Axon, 414
Chaloner, Dr. W. C. : Appointed reader in Botany, 1044
Chambaut, A. M., *et al.* : Action of Insulin on the Isolated Rat Diaphragm in the Presence of Actinomycin D and Puromycin, 1183
Champion, K. P., and Whittem, R. N. : Utilization of Increased Sensitivity of X-ray Fluorescence Spectrometry due to Polarization of the Background Radiation, 1082
Chang, Prof. C. C. : *Obituary* of Prof. J. F. Piccard, 229
Change in Rotation Period of Jupiter's Decameter Radio Sources (J. N. Douglas and H. J. Smith), 1080
Changes in the Motor Neurones after administering Muscle Relaxant and Convulsant Drugs (Y. Y. Ahmed and J. McKenzie), 385
Changes in Resistance to the Proliferation of Isotransplanted Gross Virus-induced Lymphoma Cells, as measured with a Spleen Colony Assay (A. A. Axelrad), 80

Changes occurring in the Excretion of Radiorubidium by Saliva in Rats after Whole-body Irradiation (M. Rakovič, J. Ondráčková and V. Gregora), 1008
Changes in Coenzyme (TPN) Diaphorase and TPN-linked Dehydrogenase during Axonal Reaction of the Nerve Cell (G. W. Kreutzberg), 393
"Changing Food Habits", symposium on, 540
Chapman, C. J., et *al.* : Electronically Scanned Sonar in the Investigation of Fish Behaviour, 980
Chapman, R. A. : Crab Axons showing a Prolonged Repolarization Phase, 701
Chapple, P. J., and Westwood, J. C. N. : Electron Microscopy of Myxoma Virus, 199
Charache, P., et *al.* : A Crystalline Fragment from Human Gamma-globulin, 284
Character and Allotypy of an Immune Globulin in Rabbit Colostrum (A. Feinstein), 1197
Characteristics of Benzylic Carbanions (T. J. Wallace, J. E. Hofmann and A. Schriesheim), 1287
Characterization of the Products of the Action of Bee Venom Hyaluronidase (S. A. Barker, S. I. Bayyuk, J. S. Brimacombe and D. J. Palmer), 693
Charcoal : Further Separation of Iodine, Monoiodotyrosine and Diiodotyrosine by means of Modified (I. Posner and E. Pimentel), 177
Charlesworth, Prof. J. K. : Historical Geology of Ireland, *review* by J. C. Brindley, 941
Charnock, J. S., and Post, R. L. : Evidence of the Mechanism of Ouabain Inhibition of Cation Activated Adenosine Triphosphatase, 910
Chatterjea, J. B., *et al.* : Sedimentation Characteristics of the Human Hæmoglobins, A, F and E, 919
Chayen, J., et *al.* : Behaviour of Lysomes in Hæmorrhagic Shock, 493
Chemical Alteration of Urine (Prof. R. B. Grieves and Prof. J. E. Quon), 114
Chemical Analysis : Symposia and Courses to be held at Loughborough College of Technology, 748
Chemical Engineering : S. B. Watkins appointed Professor of, 24
Chemical Etching Studies and Transmission Electron Microscopy of Silicon Carbide (T. Gabor and R. Stickler), 1054
Chemical Phenomena : Limitations of Electronic Interpretations of (Dr. C. R. Allen and Dr. P. G. Wright), 344
Chemical Radiation Damage : Influence of Crystal Defects on the Annealing of (S. R. Mohanty and S. R. Upadhyay), 169
Chemical Structure : A Physical Approach to (Prof. J. M. Robertson), 883
Chemically Reactive Surfaces : High Resolution Autoradiography of (G. T. Rogers and J. D. H. Hughes), 566
Chemically Reduced Nickel Substrates for the Development of Uniaxial Anisotropy in Electro-deposited Thin Films (R. D. Fisher and H. E. Haber), 163
Chemicals : Periodic (Liesegang) Precipitation of (A. J. Crowle et *al.*), 623
Chemiluminescent Radical Indicator : Light Emission during the Neutralization Reaction in Presence of a (H. Behrens et *al.*), 595
Chemistry : Dr. L. Crombie appointed to the chair of, 434
Dr. M. A. Leonard appointed lecturer in, 434
Prof. A. Maccoll appointed to the chair of, 430
Dr. J. MacMillan appointed lecturer in, 434
Dr. G. L. Pratt appointed lecturer in, 1044
Dr. F. G. A. Stone appointed to the chair of, 434
Dr. I. O. Sutherland appointed lecturer in, 232
Cheronis, Nicholas D. (edited by) : Proceedings of the International Symposium on Microchemical Techniques, *review* by Dr. D. T. Lewis, 945
Chester, Dr. P. F., and Bradhurst, D. H. : Electrolytically induced Conductivity in Rutile, 1056
Chesters, Prof. C. G. C. : *Obituary* of Dr. H. S. Holden, 331
Chichester, C. O., et *al.* (edited by) : Advances in Food Research, Vol. 11, *review* by Dr. Magnus Pyke, 944
Chichester, C. O., and Nakayama, T. O. M. : Astringency of Persimmons (*Diospyros kaki*, L.), 73
Chick : Effect of Orotic Acid on the Synthesis of Citrovorum Factor and of Methionine in Liver of the (G. Moruzzi et *al.*), 695
Chicken : Effect of Raw Wheat Germ on Nutrition of the (J. A. Parrish and R. J. Bolt), 398
Chickens in Graft Versus Host Reactions : Immunological Reactivity of Bursaless (N. L. Warner and A. Szenberg), 43
Chieco-Bianchi, L., et *al.* : Influence of Urethane on Susceptibility to Leukæmia Induction by Graffi Virus in Adult Mice, 292
Mast Cell Reaction and 5-Hydroxytryptamine Content in the Skin of Syrian Golden Hamsters painted with 9:10-Dimethyl-1:2-benzanthracene, 293
Chimæra in Tea : A Periclinal (I. St. E. Samarawira), 824
Chloramphenicol as revealed by Fluorescence Microscopy : Cellular Uptake of (L. Diamond), 90
Chlorella pyrenoidosa : Gigantism-inducing Factors in (M. Rodríguez-López), 506
Chlorhydroxyquinoline : Absorption of (F. M. Freeman and W. W. Heseltine), 703
Chloride : Molecular Geometry of 7a-Bromocholesteryl (J. M. Ohrt et *al.*), 1180
Chlorine Atoms : Recombination of (J. W. Linnett and M. H. Booth), 1181
Chlorine by Neutron Activation : Rapid Non-destructive Analysis of (M. Okada and Y. Kamemoto), 276
Chlorodifluoromethyl Radicals : Formation of Metastable Radicals : Isomerization of 1,2-dichloroethylene induced by (H. Derbyshire and C. R. Patrick), 68
Chlorophyll *A* : A Low-temperature Emission Band from Dilute Solutions of Pure (S. S. Brody and S. B. Broyde), 1097
Chlorophyll *A* and Crude Mixtures of Chlorophyll *A* with Normally Associated Pigments : Electron Spin Resonance of Crystalline (A. F. H. Anderson and Prof. M. Calvin), 241
Chloroplasts : Pathway of Reduction of Metmyoglobin and Nicotinamide Adenine Dinucleotide Phosphate by Illuminated (Dr. H. E. Davenport), 151
Chlorpromazine of Pylorus-ligation Ulcers in the Rat : Reduction by (R. N. Tiede et *al.*), 1296
Cholic Acid : Microbiological Dehydroxylation of (S. Hayakawa and the late K. Kurokawa), 490
Choline–Cæsium Interaction on Muscle Membrane (A. Portela et *al.*), 815
Cholinesterase : The Possible Biological Function of Pseudo- (J. W. Clitherow et *al.*), 1000
Cholinesterase Activity of Embryonic Chick Intestine in Organ Culture : Effect of Puromycin on (A. Burkhalter), 598
Cholinesterase-containing Systems of the Brain of the Rat (Dr. C. C. D. Shute and Dr. P. R. Lewis), 1160
Choroid of the Bovine Eye : Barium Content of Different Parts of the (K. Kostial-Simonovic and A. Pirie), 1007
Chromaffin Tissue of the Rat : Effect of Cortisone on Extra-adrenal (M. Lempinen), 74
Chromatid Breaks induced by Three Different Radiomimetic Compounds : Interaction of (A. Michaelis and R. Rieger), 1014
Chromatin : Analysis of Tritium-labelled Human Chromosomes and Sex (A. Bishop and O. N. Bishop), 930
Chromatographic Effluents in Argon Carrier Gas : Total Trapping of (Dr. P. A. T. Swoboda), 31
Chromatographic Techniques : Trace Analysis by Combined (C. G. Scott and C. S. G. Phillips), 66
Chromium Alloy : Growth and Nucleation of the $\beta \rightarrow \alpha$ Transformation in Uranium 0.45 per cent (A. Bar-Or et *al.*), 585
Chromosome Marker (K. R. Lewis and B. John), *review* by Dr. D. Lewis, 518
Chromosome Number of *Amphiuma* : Karotype and Revised (G. M. Donnelly and A. H. Sparrow), 1207
Chromosome Numbers for *Spartina X* townsendii and its Parent Species : Corrected (C. J. Marchant), 929
Chromosomes : Preparation of Bovine (F. Ulbrich et *al.*), 719
Chromosomes and Sex Chromatin : Analysis of Tritium-labelled Human (A. Bishop and O. N. Bishop), 930
Chromosomes from Cultures of White Blood Cells with Special Reference to the Ox : A Simple Method for the Display of (J. D. Biggers and R. A. McFeely), 718
Chymotrypsin from the Intestinal Tract : Absorption of (B. L. Kabacoff et *al.*), 815
Cicak, Anna, et *al.* : Oxygen in the Gas Vacuole of the Rhizopod Protozoan, *Arcella*, 983
Cigarette Smoke : Naphthalenes in (R. A. W. Johnstone and P. M. Quan), 1184
Ciliary Comb Plates of the Ctenophores *Beroe* and *Pleurobrachia* : Movements and Co-ordination of the (M. A. Sleigh), 620
Cirriformia tentaculata (Montagu) from Drake's Island (Plymouth Sound) and from Southampton Water : Behavioural Differences between the Larval Stages of (J. D. George), 195
Cirrus Clouds along the Magnetic Meridian : Alignment of (L. Kellner), 900
Citraconic and Mesaconic Acids in Aqueous Solution : Radiation Yield of (A. L. Fantola et *al.*), 594
Citric Acid of Germination of Eastern Red Cedar (*Juniperis virginiana* L.) : Stimulation by (C. Cotrufo), 92
Citric Acid Production and Anti-sulphonamide and Streptomycin Effect : A New Metabolic Regulator : Its Stimulation of (Dr. Z. Fencl and E. Vintrová), 905
Citrovorum Factor and of Methionine in Liver of the Chick : Effect of Orotic Acid on the Synthesis of (G. Moruzzi et *al.*), 695
Civil Research Policy : a Report of an F.B.I. Working Party, 725
Clabby, Brigadier J. : The History of The Royal Army Veterinary Corps, 1919-1961, *review* by W. A. Pool, 524

Collins, W. E., and Posner, J. B. : Electroencephalogram Alpha-activity during Mild Vestibular Stimulation, 933
Colonial Development Corporation : Annual Report 1962, 746
Colonial Research, 937
Colostrum Character and Allotypy of an Immune Globulin in Rabbit (A. Feinstein), 1197
Comet Tails : Interplanetary Magnetic Fields as a Cause of (D. B. Beard and M. P. Nakada), 580
Comitato Nazionale Energia Nucleare : Competitivity of Nuclear Energy at 1 January, 1963, 1121
Common Lands of England and Wales (Dr. W. G. Hoskins and Prof. L. Dudley Stamp), *review* by R. Hughes, 629
Common Link between Photosynthesis and Respiration in a Blue-Green Alga (L. W. Jones and J. Myers), 670
Commonwealth Bureau of Soils, Technical No. 53 : (Dr. H. L. Penman Vegetation and Hydrology), *review* by Prof. W. H. Pearsall, 316
Commonwealth Countries : Scientific and Technical Aid for, 937
Commonwealth Development Bill, 23
Commonwealth Education Scheme, 432
Commonwealth of Australia : Tenth Annual Report of the Australian Atomic Energy Commission, 544
Commonwealth Scientific and Industrial Research Organization : *Animal Research Laboratories*. Annual Report 1961-1962, 335
Annual Report of the Division of Tribophysics for 1962, 237
Colloquium on Shrinkproofing Wool (Dr. E. F. Denby and Dr. M. W. Andrews), 131
Retirement of J. K. Taylor, 1237
Appointment of Prof. E. G. Hallsworth, 1237
Commonwealth Universities Congress, 1963 (Sir James Cook, J. S. Fulton and Dr. D. G. James), 1127
Commonwealth Universities Yearbook 1963 (edited by J. F. Foster and T. Craig), *review*, 316
Communications Satellites : Proceedings of a Symposium, London, 1961 (edited by L. J. Carter), *review* by T. W. G. Dawson, 939
Community of Universities (Sir Eric Ashby), *review* by Sir James Mountford, 838
Comparative Administration Trust : Four week course in "Administration and Management of Research and Development", 232
"Comparative Biochemistry of the Leguminosae", symposium to be held, 435
Comparison of Fœtal Pulmonary Fluid with Fœtal Plasma and Amniotic Fluid (B. B. Ross), 1100
Comparison of the Disaccharides obtained from Human Blood-group A, B, H and Le^a Substances by Partial Acid Hydrolysis (Dr. T. J. Painter, Mrs. V. P. Rege and Prof. W. T. J. Morgan), 569
Comparison of Terrestrial and Universal Expansion (J. MacDougall, R. Butler, P. Kronberg and A. Sandqvist), 1080
Composition of Montan Wax (V. A. Edwards, P. J. Kipping and P. G. Jeffery), 172
Compound Semiconductors (edited by Robert K. Willardson and Harvey L. Goering), Vol. 1, *review* by Dr. A. A. Shepherd, 946
Compounds : Effect of Halogens and Interhalogen (D. Campbell *et al.*), 1090
Comprehensive Biochemistry (edited by Prof. Marcel Florkin and Prof. Elmer H. Stotz.) Vols. 1, 3 and 4, *review* by Dr. D. T. Elmore, 311
Comptonia peregrina : Fixation of Atmospheric Nitrogen by Root Nodules of (H. Ziegler and R. Hüser), 508
Computing Science : Dr. R. A. Buckingham appointed professor of, 1044
Conalbumin by Starch-gel Electrophoresis : Boric Acid-induced Heterogeneity of (W. C. Parker and A. G. Bearn), 1184
Concentrating Ejaculated Sperm for Electron Microscopy (A. Birch-Andersen and E. Blom), 201
Concentration of Nightglow H_α-emission to the Ecliptic and the Radial Velocities of this Line (Prof. P. V. Sheglov), 990
Concrete : Tobermorite Gel in (H. B. Milner), 30
Condon Loci of Molecular Spectra : Primary and Subsidiary (R. W. Nicholls), 794
Conduction Currents in Transformer Oil : Influence of Electrode Coatings on (M. C. Cullingford *et al.*), 1082
Conduction Processes in Dielectric Liquids (P. K. Watson), 646
Conference of the Universities of the United Kingdom 1962 : Report of Proceedings–Alternatives to University Education ; Relations Between the Universities and Industry, 236
Connolly, K., and Moray, Dr. N. : A Possible Case of Genetic Assimilation of Behaviour, 358
Conrad, R., and Leonard, J. A. : Maintenance of High Accuracy without Augmented Feedback, 512
Constancy Scaling : Distortion of Visual Space as Inappropriate (R. L. Gregory), 678
Constant Energy Differences in Atomic Structure (E. C. Baughan), 169
Contribution of Clinical Medicine to Physiology (Prof. J. McMichael), 887
"Contributions of Science to the Resolution of International Conflict", study conference held in Windsor, 121
"Contributions to Analytical Chemistry by Younger Members of the Profession", meeting arranged by the Society for Analytical Chemistry, 855
Conversion of Dopamine to 3,4-Dimethyoxyphenylacetic Acid in Schizophrenic Patients (Prof. A. J. Friedhoff and E. van Winkle), 1271
Convulsant Drugs : Changes in the Motor Neurones after administering Muscle Relaxant and (Y. Y. Ahmed and J. McKenzie), 385
Convulsion Therapy : Parameters of Electric Shock relevant to Electro- (R. T. Green), 307
Conway, R. G. : Measurement of Radio Sources at Centimetre Wavelengths, 1177
Cook, A. H. : European Brewery Convention : Report of the Barley Committee : Trials 1961, *review*, 525
Cook, A. M., *et al.* : Freeze-drying and Radiation Protection, 194
Cook, Sir James, *et al.* : Commonwealth Universities Congress, 1963, 1127
Cooper, J. A., *et al.* : Retention of Radiogenic Argon in Glauconites from Proterozoic Sediments, Northern Territory, Australia, 270
Cooper, J. R., *et al.* : Biochemical and Physiological Function of Thiamine in Nervous Tissue, 609
Co-ordinate Color Identifications for Industry (The National Bureau of Standards, Technical Note No. 152), 960
Copper(II) : Crystal Structure of *Bis*-(Salicyladehydato)-copper(II) and *Bis*-(8-Hydroxyquinolinato)- (J. A. Bevan *et al.*), 373
Copper by Chemisorbed Hydrogen : Equilibrium Coverage of (D. R. Rossington and S. J. Holden), 589
Copper of some Oxidizing and Reducing Bacteria : Resistance to (G. H. Booth and S. J. Mercer), 622
Corbett, J. R., and Miller, C. S. : Determination of Carbon-14 in Plant Material by Wafer Counting, 1106
Corday-Morgan Memorial Fund Executive, 1044
Cordoba, F., *et al.* : A Crystalline Fragment from Human Gamma-globulin, 284
Cormack, The Robert, Bequest Committee, a Fellowship Awarded, 540
Corner, E. J. H. : The Tropical Botanist, 888
Corona : Frequency Drift and Time Profile of 200 Mc/s Bursts of Type III and the Electron Temperature of the (O. Elgarøy and H. Rødberg), 268
Corrected Chromosome Numbers for *Spartina* X *townsendii* and its Parent Species (C. J. Marchant), 929
Correlation of Widely Spaced Magnetic Profiles in Oceanic Areas (Dr. D. H. Griffiths and R. P. Riddihough), 251
Corson, J. M., *et al.* : Homograft Antigens : Isolation of Fractions of Normal Cells which retain Activity after Freeze-drying, 499
Cortex of the Unrestrained Cat : Functional Coupling Between Cells in the Visual (J. S. Griffith and G. Horn), 876
Cortical Recruiting Responses observed during Wakefulness and Natural Sleep: Differences between (N. Yamaguchi *et al.*), 186
Cortisone on Extra-adrenal Chromaffin Tissue of the Rat : Effect of (M. Lempinen), 74
Cosmic Radiation at Different Altitudes : Simultaneous Sampling of (V. D. Hopper *et al.*), 271
Cossins, E. A., and Sinha, S. K. : Utilization of Radiosulphate by Higher Plant Tissues, 1109
Costero, I., *et al.* : Pinealoma : a Variety of Argentaffinoma ? 190
Cotrufo, C. : Stimulation by Citric Acid of Germination of Eastern Red Cedar (*Juniperis virginiana* L.), 92
Cottam, L., and Sheldon, R. P. : A Secondary Process in the Liquid-induced Crystallization of Polyethylene Terephthalate, 902
Cotton, F. Albert (edited by) : Progress in Inorganic Chemistry, Vol. 4, *review* by Dr. I. R. Beattie, 734
Coulson, C. A., and Eisenberg, D. : Energy of Formation of D-Defects in Ice, 368
Coulson, Prof. C. B. : Appointed to the chair of Biochemistry, 1237
Councils for Training of Health Visitors and Social Workers : Sir Charles Morris appointed chairman, 22
Court, Dr. M. N.: Appointed lecturer in Soil Science, 24
Cowan, W. M., *et al.* : Olfactory Relationships of the Diencephalon, 710
Cowan, W. M., and Powell, T. P. S. : Centrifugal Fibres in the Lateral Olfactory Tract, 1296
Coy, N., *et al.* : Experimental Production by 2-ethyl-2-phenyl Butyramide of Intrahepatic Cholestasis with Bile Plugs in Dogs, 498
Crab Axons showing a Prolonged Repolarization Phase (R. A. Chapman), 701
Craig, Christine : The Employment of Cambridge Graduates, 1146
Craig, G. B., and Krausz, A. S. : Technique for Producing Regular Patterns on Single Crystals, 1178
Craig, T., and Foster, J. F. (edited by) : Commonwealth Universities Yearbook 1963, *review*, 316
Cranshaw, Dr. T. E. : Annual Review of Nuclear Science, Vol. 12, *review*, 418
"Creep and Fracture" : International conference on, 122
Crispens, jun., C. G. : A Lactic Dehydrogenase Elevating Agent in Association with Human Neoplasms, 1202
Criteria for the Comparison of Skulls (A. A. Abbie), 101
Critical Testing of Substances against *Fasciola hepatica* in Sheep (J. Vodrázka), 96
Crocker, T. T., *et al.* : X-ray Inhibition of Urethan-stimulated Proliferation of Lung Cells of the Mouse as Estimated by Incorporation of Tritiated Thymidine, 1267
Crombie, Dr. L. : Appointed to the chair of Organic Chemistry, 434
Crook, Lt. Col. J. C. : Acetylcholinesterase Activity of Capillary Blood Vessels in the Central Nervous System of the Rabbit, 41
Crooks, J., *et al.* : Inhibition of Thyroid Function by a Dithiocarbamoylhydrazine, 288
Crosby, W. H., *et al.* : Reducing Agents and Absorption of Iron, 384
Cross-Stratification and Palæogeography of the Lower Greensand of South-east England and Bas-Boulonnais, France (J. Narayan), 1246
Crowe, P. F., *et al.* : Flavour of Beef and Whale Meat, 1252
Crowle, A. J., *et al.* : Periodic (Liesegang) Precipitation of Chemicals, 623
Croxatto, H., *et al.* : Effects of d,l-Aldosterone on Renal Excretion of Water, Sodium, and Potassium induced by Renin, 182
Croxson Memorial Lecture, 855
Crude Oils and their Implications to Origin of Petroleum : Distributions of *n*-Paraffins in (R. L. Martin *et al.*), 110
Cryptococcus neoformans by Capsular Polysaccharide : Immunization against (H. H. Gadebusch), 710
Crystal Defects on the Annealing of Chemical Radiation Damage : Influence of (S. R. Mohanty and S. R. Upadhyay), 169
Crystal Growth of Titanium (S. Takeuchi, H. Suzuki and O. Watanabe), 1283
Crystal Structures of *Bis*-(Salicyladehydato)-copper(II) and *Bis*-(8-Hydroxyquinolinato)-copper(II), (J. A. Bevan, D. P. Graddon and J. F. McConnell), 373
Crystalline Fragment from Human Gamma-globulin (E. J. Hershgold, F. Cordoba, P. Charache and D. Gitlin), 284
Crystallization of ω-Dicarboxylic Acids in Polymer Films (Dr. H. A. Lanceley, Dr. G. N. Richards and Dr. L. Roldan-Gozalez), 975
Crystals : Regular Inclusion Pattern in (K. G. Denbigh and E. T. White), 799
Technique for producing Regular Patterns on Single (G. B. Craig and A. S. Krausz), 1178
Ctenophores *Beroe* and *Pleurobrachia* : Movements and Co-ordination of the Ciliary Comb Plates of the (M. A. Sleigh), 620
Cucumber Viruses 3 and 4 are Strains of the same Virus; Interference Experiments relating to whether Tobacco Mosaic Virus and (Jia-Hsi Wu and S. G. Wildman), 1015
Cullingford, M. C., *et al.* : Influence of Electrode Coatings on Conduction Currents in Transformer Oil, 1082
Cultivation of Mouse Embryos *in vitro* (D. A. T. New and K. F. Stein), 297
Culture of Single Mammalian Cells (I. Yamane and Y. Matsuya), 296
Cunningham, G. J., *et al.* : Behaviour of Lysomes in Hæmorrhagic Shock, 493
Curie Point : Electrochemical Properties at the (J. K. Prall and P. R. Doidge), 800
Curran, Dr. S. C. : New Developments at Glasgow's Royal College, 843
Curtis, D. R., and Ryall, R. W. : Central Actions of Psychotomimetics, 1003
Cuticle in *Rhodnius prolixus* : Central Nervous Control of the Mechanical Properties of the (J. A. Núñez), 621
Cutin of Plant Cuticles (E. A. Baker and Dr. J. T. Martin), 1268
Cutter, Dr. E. G. : Aquatic Angiosperms, *review*, 523
Cutter, Dr. E. G., and Wardlaw, Prof. C. W. : Induction of Buds on Older Leaf Primordia in Ferns, 985

Cutting, Windsor C. (edited by) : Annual Review of Pharmacology, *review* by Dr. M. J. Rand, 210
Cyanide Acids : Infra-red Spectra of some Anhydrous Complex (D. Jones and D. F. Evans), 277
Cycadeoid Plant, A New, from the Permo-Carboniferous Coal Measures of the Transvaal (S. F. Le Roux), 1010
Cyclol Chemistry : Recent Advances in (Dr. D. Wrinch), 564
*Cyclo*pentadienils of Monovalent Indium and Thallium : Chain Structure of the (E. Frasson *et al.*), 1087
Cytochemical Demonstration of Aminopeptidase Activity in Blood Platelets (Dr. K. Balogh, jun.), 1196
Cytochemical Demonstration of Ubiquinones in Animal Tissues (J. P. Tranzer and Dr. A. G. E. Pearse), 1063
Cytochemical Measurement of Protein Sulphydryls in Cell Lines of Different Radiosensitivity (Dr. O. Caspersson and L. Révész), 153
Cytochrome *c* by *Pseudomonas fluorescens* : An Inverse Relationship of the Effects of Oxygen and Iron on the Production of Fluorescin and (H. Lenhoff), 601
Cytoplasmic Membranes : A New Repeat Structural Element of Mitochondrial and Certain (Prof. F. S. Sjöstrand), 1262
Cytotoxic Groups : Syntheses of Poly-DL-Serine Derivatives containing (M. Szekerke), 280

Development : A Selected List of United States Readings on, 23
Development of Alcohol Preference in *BALB/c* Mice (R. Kakihana and G. E. McClearn), 511
Development of British Heathlands and Their Soils (G. W. Dimbleby), *review* by Dr. R. B. Ivimey-Cook, 315
Devlin, H. B., et *al.* : A New Staphylococcal Antigen, 1074
Dewey, Dr. W. C., et *al.* : Low-voltage Electron Beam Irradiation of Normal and 5-Bromouridine Deoxyriboside-treated *L-P*$_{59}$ Mouse Fibroblast Cells *in vitro*, 780
Diagenesis : Some Aspects of (Prof. J. H. Taylor), 884
Diagnosis : Multiple Molecular Forms of Enzymes and their use in Clinical (Prof. R. J. Wieme), 437
Diamond, Dr. J. : Variation in the Sensitivity to Gamma-Amino-Butyric Acid of Different Regions of Mauthner Neurone, 773
Diamond, L. : Cellular Uptake of Chloramphenicol as revealed by Fluorescence Microscopy, 90
"Diamond Abrasives and Tools" conference sponsored by De Beers Consolidated Mines Ltd., 855
Diamonds–Anomalous X-ray Spikes Along < 111 >: Doped Synthetic (H. O. A. Meyer and H. J. Milledge), 167
Diaphragm in the Presence of Actinomycin *D* and Puromycin : Action of Insulin on the Isolated Rat (D. Eboué-Bonis et *al.*), 1183
Diaphragm Muscles : Effects of Alloxan Diabetes and Adrenaline on Concentrations of Free Fatty Acids in Rat Heart and (P. B. Garland and P. J. Randle), 381
Diazomethane : Mercuration of (A. N. Wright et *al.*), 903
Dibenzyl Hyponitrites : Effect of Alkyl and Halo Substituents on the Homolytic Dissociation of (J. B. De Sousa), 64
ω-Dicarboxylic Acids in Polymer Films : Crystallization of (Dr. H. A. Lanceley et *al.*), 975
1,2-dichloroethylene induced by Chlorodifluoromethyl Radicals : Formation of Metastable Radicals : Isomerization of (H. Derbyshire and C. R. Patrick), 68
Dickinson, Carola I. : British Seaweeds, *review* by Prof. L. Newton, 417
Dielectric Liquids : Conduction Processes in (P. K. Watson), 646
Dielectric Loss and Hydration of Sodium Chabazite (R. M. Barrer and P. J. Coen), 587

Dielectric Properties of Cross-linked Polystyrene Film formed in the Glow Discharge (M. Stuart), 59
Diencephalon : Olfactory Relationships of the (T. P. S. Powell *et al.*), 710
Diepoxybutane : Differential Mutagenic Activity of *l*(+) and *d*(—) (J. Moutschen-Dahmen *et al.*), 406
Diesel Engine Maintenance : Spectrographic Analysis as an Aid to (H. B. Milner), 652
Diet, Influence of, on Urine Concentration in *Aplodontia rufa* and the Rabbit (E. W. House, E. W. Pfeiffer and H. A. Braun), 181
Differences between Cortical Recruiting Responses observed during Wakefulness and Natural Sleep (N. Yamaguchi, G. M. Ling and T. J. Marczynski), 186
Differences in the Disposition of Endogenous and Exogenous Substances by Cells (A. V. Furano and J. P. Green), 380
Different 'Spectra' of Mutant Types of Extra-cellular Treatment of Phage Kappa with Differing Mutagens (R. W. Kaplan, H. Beckmann and W. Rüger), 932
Differential Behaviour of Transplanted Mouse Lymphoma Lines in Genetically Compatible Homozygous and F_1 Hybrid Mice (K. E. Hellström), 614
Differential Mutagenic Activity of *l*(+) and *d*(—) Diepoxybutane (J. Moutschen-Dahmen, M. Moutschen-Dahmen and R. Loppes), 406
Dihydroxyphenylalanine by Antidepressants and Stimulants : Potentiation of the Anti-reserpine Effects of (W. R. McGrath and H. J. Ketteler), 917
Diidroquinidine on Isolated Hearts of Mammals : Photodynamic Effect of (G. Pace and W. Pierpaoli), 915
Diiodotyrosine by means of Modified Charcoal : Further Separation of Iodine, Monoiodotyrosine and (I. Posner and E. Pimentel), 177
Di-isobutyl Aluminium Hydride with Stannic Chloride : Reaction of (T. D. Smith), 374
Dimbleby, G. W. : The Development of British Heathlands and Their Soils, *review* by Dr. R. B. Ivimey-Cook, 315
3-Dimensional Shapes, Use of, for Investigation of Learning Sets in the Rat (H. Kay and H. Oldfield-Box), 1018
3,4-Dimethoxyphenylacetic Acid in Schizophrenic Patients : Conversion of Dopamine to (Prof. A. J. Friedhoff and E. van Winkle), 1271
3,4-Dimethoxyphenylethylamine and Other Amines in the Urine of Schizophrenic Patients (M. Takesada, Y. Kakimoto, I. Sano and Z. Kaneko), 203 ; (A. J. Friedhoff and E. Van Winkle), 204
9:10-Dimethyl-1:2-Benzanthracene : Mast Cell Reaction and 5-Hydroxytryptamine Content in the Skin of Syrian Golden Hamsters painted with (L. Chieco-Bianchi *et al.*), 293
9,10-Dimethyl-1,2-Benzanthracene with Subsequent Local Continuous Exposure to 'Tween 40' : A Stochastic Model of Carcinogenesis compared with Mouse Skin Tumour Enhancement after Gastric Instillation of (E. E. Niskanen and W. Arley), 83
2,4-Dinitrophenol on Anion Transport by an Intestinal *in vitro* Preparation : Influence of (V. Capraro *et al.*), 1099
Dinoflagellates from Upper Triassic Sediments : Fossil (Dr. W. A. S. Sarjeant), 353
Dintenfass, L. : Blood Rheology in Cardio-vascular Diseases, 813
Dionne, R. D., *et al.* : An Indication of Underwater Sound Production by Squid, 250
Diospyros kaki, L. : Astringency of Persimmons (T. O. M. Nakayama and C. O. Chichester), 73
Diploid-like Pairing in a Synthetic Decaploid *Avena* (H. Thomas), 1209
Dipole Time : Ready Method for finding Eccentric (K. D. Cole and G. V. Simonow), 1279
Diquat and Paraquat : A Sensitive Method for Determination of Low Concentrations of (H. H. Funderburk, jun., and J. M. Lawrence), 1011
Direct Electron-optical Resolution of Anti-phase Domains in a Silicate (J. D. C. McConnell and S. G. Fleet), 586
Directorate of Overseas Surveys, 1230
Disaccharides obtained from Human Blood-group A, B, H and Le^a Substances by Partial Acid Hydrolysis : A Comparison of the (Dr. T. J. Painter *et al.*), 569
Disarmament and Arms Control, (I, No. 1 ; Summer 1963), 746
Discharge-flow Experiments : Some Reactions of Ozone in (Dr. M. A. A. Clyne *et al.*), 1057
Diseases of Free-living Wild Animals (FAO Agricultural Studies No. 57), 121
Diseases of Porphyrin Metabolism (A. Goldberg and Prof. C. Rimington), *review* by Prof. C. H. Gray, 1222
Dislocations and Catalysis (J. W. Hall and H. F. Rase), 585
Dissociation Energies of the Alkaline Earth Monofluorides (G. D. Blue, J. W. Green, T. C. Ehlert and J. L. Margrave), 804
Dissolution of Glass at Elevated Temperatures (G. Butler and H. C. K. Ison), 998
Distantiella theobroma (Dist.) : Insecticide Resistance in the Cocoa Capsid (J. A Dunn), 1207
Distinguishing between the Solar, the Interplanetary and Geomagnetic Fields (K. D. Cole), 897
Distortion of Visual Space as Inappropriate Constancy Scaling (R. L. Gregory), 678
Distributions of *n*-Paraffins in Crude Oils and their Implications to Origin of Petroleum (R. L. Martin, J. C. Winters and J. A. Williams), 110
Disulphide Bond : Preparation of an Insulin A Chain Derivative with an Intact Intra-chain (J. Meienhofer and O. Brinkhof), 1095
Disulphide Bonds of Pepsinogen : Reduction and Reoxidation of the (V. Frattali *et al.*), 1186
Disulphides : Interchange Reactions of (E. R. Cole, 198, 1083), *erratum*, 855
Ditchburn, Prof. R. W. : Light, second edition, *review*, 734
Dithiocarbamoylhydrazine : Inhibition of Thyroid Function by a (M. I. Tulloch *et al.*), 288
Diurnal Fluctuations in the Numbers of DNA Synthesizing Nuclei in Various Mouse Tissues (C. Pilgrim, W. Erb and W. Maurer), 863
Diurnal Rhythms of Electrolyte Excretion in Depressive Illness (M. Lobban, B. Tredre, Dr. A. Elithorn and Dr. P. Bridges), 667
Divers : A Theoretical Model for the Computation of Decompression Tables for (A. Göransson *et al.*), 384
Division Cycle of Partially Synchronized Chinese Hamster Cells in Culture : Variations in X-ray Response during the (Dr. W. K. Sinclair and R. A. Morton), 1158
Dixon, G. J., *et al.* : Inhibition of 6-Mercaptopurine-resistant Cancer Cells in Culture by *Bis*(Thioinosine)-5′, 5‴-Phosphate, 769
Dobelle, W. H., and Witt, R. K. : Preparation of Sieves with Microscopic Pore Diameters, 1288
"Documentation of Science Organization as an Emerging New Branch of Scientific Information" (G. Rózsa, *Bibliographical Publications of the Scientific Academy of Hungary*,) No. 32, 747
Dobbs, C. G., and Griffiths, D. A. : Relationships between Mycostasis and Free Monosaccharides in Soils, 408
Dodd, J. M., and Dent, J. N. : Thyroid Gland and Temperature Tolerance Relationships in Cold-blooded Vertebrates, 299
Dodds, Dr. K. S. : An Introduction to Genetics, *review*, 734
Dodgson, J. : Use of Interference Microscopy for the Mineralogical Analysis of Samples of Airborne Dust obtained with the Thermal Precipitator, 245
Dog : Intestinal Degradation of Gamma-globulin in the (S. B. Andersen *et al.*), 1096
Dogs : Experimental Production by 2-ethyl-2-phenyl Butyramide of Intrahepatic Cholestasis with Bile Plugs in (C. H. Keysser *et al.*), 498
Doidge, P. R., and Prall, J. K. : Electrochemical Properties at the Curie Point, 800
Dolerite Dykes : Significance of Differences in Magnetization Along Certain (Dr. D. W. Powell), 674
Dolphin, D. H., *et al.* : Sulphitocobalamin, 170
Domestic Animals : The Behaviour of (edited by Prof. E. S. E. Hafez), *review* by Dr. W. H. Thorpe, 522
Donato, A., and Bolognari, A. : Presence of Ribonucleic Acid in the Initial Yolk Globules of Oocytes of *Aplysia depilans* L., 697
Donnelly, G. M., and Sparrow, A. H. : Karotype and Revised Chromosome Number of *Amphiuma*, 1207
Dopamine to 3,4-Dimethoxyphenylacetic Acid in Schizophrenic Patients : Conversion of (Prof. A. J. Friedhoff and E. van Winkle), 1271
Doped Synthetic Diamonds–Anomalous X-ray Spikes Along $<111>$ (H. O. A. Meyer and H. J. Milledge), 167
Dormancy Regulators in Woody Plants (C. F. Eagles and P. F. Wareing), 874 ; (P. M. Robinson, P. F. Wareing and T. H. Thomas), 875
Dormer, Dr. K. J. : Plant Hairs (Handbuch der Pflanzenanatomie, Band IV, Teil 5), *review*, 525
Dose-effect Relationships for Radiation Damage to Organized Tissues (J. F. Fowler, D. K. Bewley, R. L. Morgan, J. A. Silvester, T. Alper and S. Hornsey), 253
Douglas, J. N., and Smith, H. J. : Change in Rotation Period of Jupiter's Decameter Radio Sources, 1080
Douzou, P., and Ptak, M. : Examination of Optically Excited Amino-Acids by Electron Spin Resonance at Very Low Temperature, 1092
Dowden, D. A. : Advances in Catalysis and Related Subjects, Vol. 13, *review*, 727
Dowling, J. E., and Hubbard, R. : Effect of Instantaneous Flashes on Adaptation of the Eye, 972
Downes, A. M., *et al.* : Separate Synthesis of Fibrillar and Matrix Proteins in the Formation of Keratin, 1059
Drago, F. G., *et al.* : Solar Flux Fluctuations at 225 Mc/s and Noise-level of Atmospherics at 27 Kc/s, 363
Drake's Island (Plymouth Sound) and from Southampton Water : Behavioural Differences between the Larval Stages of *Cirriformia tentaculata* (Montagu) from (J. D. George), 195
Dravnieks, A. : Hydrogen–Air Fuel Cell with Homogeneous Oxidation Catalyst Redox Cycle, 1182
Dray, Dr. S., *et al.* : Distribution of Allotypic Specificites among Rabbit γ-Globulin Molecules Genetically Defined at Two Loci, 52
'Dream Time' in Hallucinating and Non-hallucinating Schizophrenic Patients (R. L. Koresko, F. Snyder, and I. Feinberg); 1118
Drew, D. H. : A Nutrient Requirement for Optimum Water Absorption by Intact Root Systems, 93
Drews, G., and Jaeger, K. : Influence of Light on the Biosynthesis of Bacteriochlorophyll by *Rhodopseudomonas spheroides*, 1112
Dreyfus, Stuart E., and Bellman, Richard E. : Applied Dynamic Programming, *review* by J. J. Florentin, 6
Drone Production in Honey-Bee Colonies (*Apis mellifera* L.) (Dr. M. E. Allen), 789
Drosophila : Induction of Mutations and Killing of Cells in Irradiated Spermatogonia of (P. Oftedal), 1301
Drug Action : Enzymes and (edited by Dr. J. L. Mongar and A. V. S. de Reuck) Ciba Foundation Symposium, jointly with the Co-ordinating Committee for Symposia on Drug Action, *review* by Dr. G. A. Snow, 418
Drugs : Thymectomy in Dogs with Renal Homografts treated with (R. Y. Calne), 388
Dryden, Hugh L. : *Obituary* of Dr. T. von Kármán, 10
'Duazomycin A' : Enhanced Suppression of the Secondary Immune Response by Combination of 6-Mercaptopurine (S. Rosenberg and P. Calabresi), 1101
Duke, D. I., *et al.* : Assessment of Functional Competence in Isolated Muscular Tissues, 494
Dulmage, E. A., *et al.* : Inhibition of 6-Mercaptopurine-resistant Cancer Cells in Culture by *Bis*(Thioinosine)-5′, 5‴-Phosphate, 769
Dumont, A. E., and Sohn, N. : Effect of 5-Fluorouracil on Regeneration in Tadpoles, 617
Dunbar, Dr. J. M. : Appointed lecturer in Bacteriology, 434
Dunn, J. A. : Insecticide Resistance to the Cocoa Capsid, *Distantiella theobroma* (Dist.), 1207
Duplex Origin of Petroleum (Sir Robert Robinson), 113
Duration of Antibody Response to Soluble Antigen (R. V. Gilden and G. L. Rosenquist), 87
Dust : Suppression of (Dr. R. G. Burdon), 994
Dust obtained with the Thermal Precipitator : Use of Interference Microscopy for the Mineralogical Analysis of Samples of Airborne (J. Dodgson), 245
Dust, Radioactivity of Air, Rain Water and Turf Grass in Bandung, Java (A. Suszkin), 584
Dyes : Electron Spin Resonance in Photodynamic (L. P. Simpson *et al.*), 243
Dykes : Significance of Differences in Magnetization Along Certain Dolerite (Dr. D. W. Powell), 674
Dykes, Assynt, and their Metamorphism (J. Tarney), 672
Dyster-Aas, K., and Krakau, C. E. T. : Effect of Melanocyte-stimulating Hormone on the Eye of the Rabbit, 76

EAGLES, C. F., and Wareing, P. F. : Dormancy Regulators in Woody Plants, 874
Ear Chamber, Use of, with Uterine Muscle Transplant to differentiate Myometrial and Vascular Activity (W. J. Cliff, J. D. Martin and C. A. Michael), 399
Eardley, Prof. E. J. : Structural Geology of North America, *review*, 6
Earle, K. M., *et al.* : Pinealoma : a Variety of Argentaffinoma? 190
Earnshaw, Dr. A., *et al.* : Five Co-ordinate Compounds of Cobalt, 483
Earth, A New Calculation for the Age of the, from Abundances of Lead Isotopes (Dr. R. G. Ostic *et al.*), 1150
Earth Conditions : Synthesis of Adenosine Triphosphate under possible Primitive (Dr. C. Ponnamperuma *et al.*), 222
Earthquake in Jugoslavia, 431
Earthquakes : The Zone of Fracture, and the Wave Spectrum of (Dr. Hans Berckhemer), 747
Earth's Orbital Position : Ionospheric Effects Due to the (Dr. G. Noci), 968
Earthworms : The Physiology of (M. S. Laverack), *review* by Dr. R. Phillips Dales, 314
East African Academy : First Symposium and Inaugural Annual General Meeting (T. R. Odhiambo), 439
Eastern Red Cedar (*Juniperis virginiana* L.) : Stimulation by Citric Acid of Germination of (C. Cotrufo), 92
Easty, D. M., and Easty, G. C. : Organ Culture System for the Examination of Tumour Invasion, 1104
Easty, G. C., and Easty, D. M. : Organ Culture System for the Examination of Tumour Invasion, 1104
Easty, G. C., *et al.* : Infiltration of Intra-abdominal Organs by Ascites Tumours, 188
Eboué-Bonis, D., *et al.* : Action of Insulin on the Isolated Rat Diaphragm in the Presence of Actinomycin D and Puromycin, 1183

Eccles, Sir John, et *al.* : Identification of Inhibitory Neurones in the Hippocampus, 699
Inhibitory Synapses on Somas of Purkinje Cells in the Cerebellum, 655
Echinococcus granulosus in vitro : Secretory Activity by the Scolex of (J. D. Smyth), 402
Ecology : Unity of (Dr. F. F. Darling), 885
Ectopically Placed Autologous Tissues : An Attempt to demonstrate *in vivo* Recognition of (M. R. Anderson), 712
Edelhoch, H., et *al.* : Reduction and Reoxidation of the Disulphide Bonds of Pepsinogen, 1186
Eden, Dr. A. : Nutrition of Pigs and Poultry : Proceedings of the University of Nottingham Eighth Easter School in Agricultural Sciences, 1961, *review*, 521
Edinburgh, Duke of : The Handley Page Memorial Lecture, 627
Education : Field Studies in, 311
Managerial and Commercial (Dr. J. Rose), 953
Personal Values in (Sir Charles Morris), 889
Technology in Higher, 627
Transition from Primary to Secondary, 23
Education in Britain : Primary and Secondary, 745
Research into, 856
Education in Materials Science (L. Holliday, Prof. J. G. Ball, Dr. P. E. Evans and Dr. J. B. Brennan), 233
Educational Policy in Britain, 1045
Edwards, Dr. E. G. : Colleges of Advanced Technology in Britain, 1131
Edwards, J. G., and Mathias, A. P. : Apparatus for the Automatic Location of Absorbing Components separated by Density Gradient Centrifugation, 603
Edwards, J. H., and Guli, E. : Meiotic Investigations in Man, 1114
Edwards, Prof. S. F. : Appointed to the chair of Physics, 643
Edwards, V. A., et *al.* : Composition of Montan Wax, 171
Effect of Alkyl and Halo Substituents on the Homolytic Dissociation of Dibenzyl Hyponitrites (J. B. De Sousa), 64
Effect of Anxiety on Real and Ideal Vocational Aspiration among Grammar School Boys (L. W. Littig), 1214
Effect of 8-Azaguanine on the Specificity of Antigens synthesized by *E.coli B/r*s (G. M. Pontieri and O. J. Plescia), 191
Effect of Benzquinamide on Blood Pressure (J. de Palol), 1102
Effect of Carbon Dioxide on Evaporation of Water (Frank Sechrist), 899
Effect of Certain Soil Organisms on the Eggs of Parasitic Roundworms (H. Lýsek), 925
Effect of Cortisone on Extra-adrenal Chromaffin Tissue of the Rat (M. Lempinen), 74
Effect of 3,4-Dehydro-DL-Proline on Growth and Protein Synthesis (Dr. L. Fowden, S. Neale and H. Tristram), 35
Effect of Different Vasomotor Agents on the Vasco-elastic Behaviour of Arteries of the Muscular Type (H. Kulbertus), 1193
Effect of Diurnal Freeze-Thawing on Survival and Growth of Selected Bacteria (R. S. Young, P. Deal, J. Bell and J. Allen), 1078
Effect of Electron Donors on the Isotopic Exchange between Aluminium (III), Gallium (III) and Indium (III) Iodides and Alkyl Iodides (A. Polaczek and A. Halpern), 1286
Effect of Electrostatic Fields on Cell Mitosis (L. Bozóky, Gy. Kiszely, T. A. Hoffmann and J. Ladik), 1306
Effect of 5-Fluorouracil on Regeneration in Tadpoles (A. E. Dumont and N. Sohn), 617
Effect of Gibberellin on Varietal Identity in Red Clover (Trifolium pratense L.), (Dr. J. L. Stoddart), 1270
Effect of Instantaneous Flashes on Adaptation of the Eye (W. A. H. Rushton), 971 ; (J. E. Dowling and R. Hubbard), 972
Effect of Liver Regeneration following Partial Hepatectomy on the Uptake of Tritiated Thymidine in the Pituitary Gland of the Rat (R. M. Nakamura, D. S. Miyada and D. L. Moyer), 707
Effect of Low Temperature on the Induction of Imaginal Differentiation of Dauer Pupa of the Silkworm (M. Kobayashi and W. J. Burdette), 826
Effect of Melanocyte-stimulating Hormone on the Eye of the Rabbit (K. Dyster-Aas and C. E. T. Krakau), 76
Effect of *Mycobacterium tuberculosis H37Rv* grown *in vivo* (*LH37Rv*) on Ehrlich Carcinoma Ascites Cells (M. Artman and A. Bekierkunst), 1308
Effect of Phenolase on Anthocyanins (C. Y. Peng and P. Markakis), 597
Effect of Protein Depletion on Amino-acid Activating Enzymes of Rat Liver (A. Mariani, M. A. Spadoni and G. Tomassi), 378
Effect of Puromycin on Cholinesterase Activity of Embryonic Chick Intestine in Organ Culture (A. Burkhalter), 598
Effect of Raw Wheat Germ on Nutrition of the Chicken (J. A. Parrish and R. J. Bolt), 398
Effect of Scabs on the Rate of Epidermal Regeneration in the Skin Wounds of Guinea Pigs (M. Zahir), 1013
Effect of Some Organic Additives on Conduction Current and Breakdown of Insulating Liquids (L. Angerer), 62
Effect of Starvation on Adenosine Triphosphate Concentration in *Aerobacter aerogenes* (R. E. Strange, H. E. Wade and F. A. Dark), 55
Effect of Thalidomide on the Development of the Chick Embryo (C. A. De Bock and A. Peters), 1204
Effect of Thymectomy on the Induction of Skin Tumours by 3,4-Benzopyrene (J. F. A. P. Miller, G. A. Grant and F. J. C. Roe), 920
Effect of Thyroxin on the Fine Structure of the Rat Liver Cell (G. E. Paget and J. M. Thorp), 1307
Effect of Thyrotropin on Nucleic Acids and Protein Contents of the Thyroid (R. Ekholm and V. Pantić), 1203
Effect of Ultra-violet Light on Skin Collagen (Eva Bottoms and S. Shuster), 192
Effects of Air, Oxygen and 20 per cent Carbon Dioxide on the Rabbit during Surface Cooling Down to Cardiac Arrest (Dr. B. Broom), 1155
Effects of Alloxan Diabetes and Adrenaline on Concentrations of Free Fatty Acids in Rat Heart and Diaphragm Muscles (P. B. Garland and P. J. Randle), 381
Effects of Amphetamine and Pentobarbitone on Exploratory Behaviour in Rats (Dr. R. Stretch), 787
Effects of Atomic Radiation (C. Auerbach) (198, 343), 539
Effects of Federal Programs on Higher Education (Harold Orlans), *review* by Sir Harry Melville, 837
Effects of Lysergic Acid Diethylamide on the Total Leukocytes and Eosinophils of the Female Rat (A. M. Sackler, A. S. Weltman and S. B. Sparber), 1194
Effects of Magnetic Fields on Tomato Ripening (A. A. Boe and D. K. Salunkhe), 91
Effects of Plant Growth Regulators (Auxins and Auxin Esters) on the Survival of Free Cells of the Ehrlich Ascites Carcinoma (Dr. R. D. Schultz and Dr. D. Norman), 260
Effects of Radiation on Transistors in the First *Telstar* Satellite (D. S. Peck and E. R. Schmid), 741
Effects of X-rays on Electrical Activity in the Eye of the Cockroach *Blaberus giganteus* (W. F. Baldwin, J. B. Sutherland and J. E. J. Habowsky), 616
Effluent by Flotation : Decontamination of Synthetic (R. L. Cardozo and P. Dejonghe), 687
Egg Shell : Carbonic Anhydrase and Formation of the Hen's (D. S. Robinson and N. R. King), 497
Egg Yolk of Plasmalogenic Triglycerides : Occurrence in (M. Proštenik and M. Popović), 1285
Eggs of Parasitic Roundworms : Effect of Certain Soil Organisms on the (H. Lýsek), 925
Eggers, H. J., and Tamm, I. : Synergistic Effect of 2-(α-Hydroxybenzyl)-benzimidazole and Guanidine on Picornavirus Reproduction, 513
Ehlert, T. C., et *al.* : Dissociation Energies of the Alkaline Earth Monofluorides, 804
Ehricke, Krafft A. : Space Flight, Vol. 2, *review* by D. G. King-Hele, 1125
Ehrlich Ascites Carcinoma : Effects of Plant Growth Regulators (Auxins and Auxin Esters) on the Survival of Free Cells of the (Dr. R. D. Schultz and Dr. D. Norman), 260
Ehrlich Carcinoma Ascites Cells : Effect of *Mycobacterium tuberculosis H37Rv* grown *in vivo* (*LH37Rv*) on (M. Artman and A. Bekierkunst), 1308
Eifert, A., and Eifert, J. : Maximum of Starch during Spring in the Woody Plants (*Vitis riparia* Michx.), 825
Eifert, J., and Eifert, A. : Maximum of Starch during Spring in the Woody Plants (*Vitis riparia* Michx.), 825
Eight Co-ordination in the Early Transition Series (Dr. R. J. H. Clark, D. L. Kepert, Prof. R. S. Nyholm and Prof. J. Lewis), 559
Einstein's Diffusion–Mobility Relationship : A Fundamental Extention of (E. R. Pike), 994
Eisenberg, D., and Coulson, C. A. : Energy of Formation of D-Defects in Ice, 368
Eisenia foetida (Sav.) : Heat-death Temperature in *Allolobophora terrestris* (Sav.) forma *longa* (Ude) and (H. B. Miles), 826
Eisma, E., and Schenck, P. A. : Determination of *n*-Alkanes in Mixtures of Saturated Hydrocarbons by Means of Gas Chromatography, 170
Ekholm, R., and Pantić, V. : Effect of Thyrotropin on Nucleic Acids and Protein Contents of the Thyroid, 1203
Ekman, V. W. : "On the Influence of the Earth's Rotation on Ocean Currents", reprint of paper published 1905, 645
Elasticity or Heat Conduction : Inhomogeneous Problems in (Prof. H. S. Heaps), 477
Eldine, M. E. Z., et *al.* : Influence of Electrode Coatings on Conduction Currents in Transformer Oil, 1082
Electric Field : Liquid Crystals in an (R. Williams), 273
Polymerization of a Thermosetting Polymer in an (R. W. Warfield and M. C. Petree), 67
Electric Power in Scotland, 431
Electric Receptors in a Non-electric Fish (*Clarias*), (H. W. Lissmann and K. E. Machin), 88
Electric Shock relevant to Electro-convulsion Therapy : Parameters of (R. T. Green), 307
Electrical Activity in the Eye of the Cockroach *Blaberus giganteus* : Effects of X-rays on (W. F. Baldwin et *al.*), 616
Electrical Breakdown in Vaccum : Possible Transition in the Initiating Mechanism Leading to (Dr. R. Hawley), 978
Electrical Conductivity of Ammonium Perchlorate (Dr. P. Zirkind and Dr. E. S. Freeman), 1280
Electrical Conductivity of Solutions of Aluminium (III), Gallium (III) and Indium (III) Iodides in Alkyl Iodides (A. Halpern and A. Polaczek), 1286
Electrical Engineering : Prof. H. A. Prime appointed to the chair of, 430
Electrical Stimulation of Pain and Touch Systems (R. H. Gibson), 307
Electricity Supply Industry : Technical Developments in the (Dr. H. Taylor). Substance of the Fifteenth W. M. Thornton Lecture delivered during the Convention of the Association Mining Electrical and Mechanical Engineers, 419
Electrochemical Method : Extensive Reduction of Coal by a New (R. E. Markby et *al.*), 997
Electrochemical Properties at the Curie Point (J. K. Prall and P. R. Doidge), 800
Electrode Coatings on Conduction Currents in Transformer Oil : Influence of (M. C. Cullingford et *al.*), 1082
Electroencephalogram Alpha-activity during Mild Vestibular Stimulation (W. E. Collins and J. B. Posner), 933
Electro-Heat, International Congress on, 540
Electrolyte : Reduction of Oxygen at a Carbon Electrode Emerging from an (S. R. Faris), 754
Electrolyte Excretion in Depressive Illness : Diurnal Rhythms of (M. Lobban et *al.*), 667
Electrolytically induced Conductivity in Rutile (Dr. P. F. Chester and D. H. Bradhurst), 1056
Electron-acceptor Properties and Carcinogenic Activity of Organic Molecules : Electron-donor or (B. Pullman and A. Pullman), 467 ; (A. C. Allison and T. Nash), 469
Electron Affinity of Tetracyanoethylene (F. M. Page and J. Kay), 483
Electron Affinity Spectrometry : High-sensitivity Detection of Amino-acids by Gas Chromatography and (Prof. R. A. Lansdowne and Prof. S. R. Lipsky), 141
Electron-donor or Electron-acceptor Properties and Carcinogenic Activity of Organic Molecules (B. Pullman and A. Pullman), 467 ; (A. C. Allison and T. Nash), 469
Electron-donors on the Isotopic Exchange between Aluminium (III), Gallium (III) and Indium (III) Iodides and Alkyl Iodides : Effect of (A. Polaczek and A. Halpern), 1286
Electron Irradiation on the Young's Modulus of Graphite : Some Effects of (P. R. Goggin), 367
Electron Linear Accelerator : High-current Cathode for (J. Haimson and I. Brodie), 795
Electron Microscope Examination of Myoglobin (K. Deutsch), 180
Electron Microscopy : Concentrating Ejaculated Sperm for (A. Birch-Andersen and E. Blom), 201
Electron Microscopy of Myxoma Virus (P. J. Chapple and J. C. N. Westwood), 199
Electron Microscopy of Silicon Carbide : Chemical Etching Studies and Transmission (T. Gabor and R. Stickler), 1054
Electron Paramagnetic Resonance in Non-irradiated Bone (R. O. Becker), 1304
Electron-Probe Microanalysis of Anodic Oxide Films on Aluminium Alloys (Dr. G. C. Wood, V. J. J. Marron and B. W. Lambert), 239
"Electron Probe X-ray Microanalysis" postgraduate course to be held at Bristol College of Science and Technology, 748
Electron Spin Resonance at Very Low Temperature : Examination of Optically Excited Amino-acids by (M. Ptak and P. Douzou), 1092
Electron Spin Resonance in Photodynamic Dyes (L. P. Simpson, J. S. Kirby-Smith and M. L. Randolph), 243
Electron Spin Resonance in Polymer Carbons : Effect of Halogens and Interhalogen Compounds (D. Campbell, C. Jackson and W. F. K. Wynne-Jones), 1090
Electron Spin Resonance of Crystalline Chlorophyll *A* and Crude Mixtures of Chlorophyll *A* with Normally Associated Pigments (A. F. H. Anderson and Prof. M. Calvin), 241
Electron Spin Resonance Spectra in Various Clay Minerals (H. Z. Friedlander, J. Saldick and C. R. Frink), 61
Electron Spin Resonance Spectrometer : Use of Long Cavities for Aqueous Samples in an (Dr. T. H. Wilmshurst), 477

Electronic Interpretations of Chemical Phenomena : Limitations of (Dr. C. R. Allen and Dr. P. G. Wright), 344
Electronically Excited Neutral Particles with Alkali Metal Atoms : Mass Spectrometric Investigation of Reactions of (Z. Herman and V. Čermák), 588
Electronically Scanned Sonar in the Investigation of Fish Behaviour (Dr. V. G. Welsby et *al.*), 986
"Electronics Research and Development for Civil Aviation", programme of displays and lectures on, 540
Electrons : Splitting of Uracil Dimer by High-energy (B. Schmidt et *al.*), 504
Electrons and of Atomic Hydrogen in γ-irradiated Ice : Formation of (L. Kevan et *al.*), 689
Electrons by Standing Waves of Light : Stimulated Compton Scattering of (A. C. Hall), 683
Electrophoresis : A Rapid Method of Disk (J. Broome), 179
Electrophoretic and Sedimentation Experiments : Analysis of Reversibly Interacting Systems by Differential Boundaries in (G. A. Gilbert and R. C. Ll. Jenkins), 688
Electrostatic Fields on Cell Mitosis : Effect of (L. Bozóky et *al.*), 1306
Elementary Particles : a Short History of some Discoveries in Atomic Physics (The Vanuxem Lectures, 1959) by Chen Ning Yang, 1122
"Elementary Particles", international conference on, 540
Elephant Shrews : Hæmoglobins of Two (J. Buettner-Janusch and V. Buettner-Janusch), 918
Eley, D. D., et *al.* (edited by) : Advances in Catalysis and Related Subjects, Vol. 13, *review* by D. A. Dowden, 727
Eigarøy, O., and Rødberg, H. : Frequency Drift and Time Profile of 200 Mc/s Bursts of Type III and the Electron Temperature of the Corona, 268
Elithorn, Dr. A., et *al.* : Diurnal Rhythms of Electrolyte Excretion in Depressive Illness, 667 ; A Mathematical Model of a Perceptual Maze Test, 676
Elliott, P., et *al.* : Working Model of the Mechanical Escapement in Su Sung's Astronomical Clock Tower, 1242
Elliott, R. B., and Evans, W. D. : Beacon Sandstone : its Petrology and Hydrocarbon Content, 686
"Ellipsometer and its Use in the Measurement of Surfaces and Thin Films", symposium on, 435
Ellis, John, and Engel, Charles (edited by) : *Television in the Medical School*, 854
Elmore, Dr. D. T. : Comprehensive Biochemistry Vols. 1, 3 and 4, *review*, 311
Elution Procedure for the Demonstration of Methæmoglobin in Red Cells of Human Blood Smears (E. Kleihauer and K. Betke), 1196
Embryo, Chick : Effect of Thalidomide on the Development of the (C. A. De Bock and A. Peters), 1204
Embryonic Central Nervous System : Minute Structure of the Inner Surface of an (R. Jelínek and E. Klika), 394
Embryonic Chick Intestine in Organ Culture : Effect of Puromycin on Cholinesterase Activity of (A. Burkhalter), 598
Embryonic Tissue by Trypsin : Inhibition by Trypsin Inhibitors of Dissociation of (A. A. Moscona), 379
Embryos *in vitro* : Cultivation of Mouse (D. A. T. New and K. F. Stein), 297
Embryos, Sheep, and the Simulation of Intra-uterine Life : Resuscitation of (A. W. Marrable), 97
Emmons, H. W., and Lick, W. J. : Thermodynamic Properties of Helium to 50,000°K, *review* by Dr. I. R. Hurle, 525
Employment of Cambridge Graduates (Christine Craig), 1146
Enamel Matrix : Mineralization of Keratin and its Comparison with the (Dr. F. G. E. Pautard), 531
Encephalomyocarditis Virus Ribonucleic Acid : Replicative Form of (Dr. L. Montagnier and Dr. F. K. Sanders), 664
Encouragement of Scientific Research in Britain, 725
Endocrinology : Asia and Oceania Congress of (I. G. Jarrett), 858
Endogenous and Exogenous Substances by Cells : Differences in the Disposition of (A. V. Furano and J. P. Green), 380
Endomycopsis selenospora : Ascospores of (N. J. W. Kreger-van Rij and J. P. van der Walt), 1012
Energetics of Ion Molecule Reactions in Alkanes (Dr. L. Kevan), 562
Energy and the European Economic Community, 132
Energy of Formation of D-Defects in Ice (D. Eisenberg and C. A. Coulson), 368
Engel, Charles, and Ellis, John (edited by) : *Television in the Medical School*, 854
Engelhardt, Dr. V. A. : Elected foreign member, The Royal Society, Edinburgh, 119
English : Literacy of Scientists and Teachers of (A. E. Darbyshire), 737
Enhanced Photoreactivity of Riboflavin in Aqueous Solution in the Presence of Macromolecules (H. B. Kostenbauder and P. P. DeLuca), 999
Enhanced Suppression of the Secondary Immune Response by Combination of 6-Mercaptopurine 'Duazomycin A' (S. Rosenberg and P. Calabresi), 1101
Enteroviruses by Non-cultured Bovine and Human Tissues : Adsorption *in vitro* of Bovine (M. La Placa), 1211
Entomologie Appliquée à l'Agriculture Traité publié sous la direction de Prof. A. S. Balachowsky, Tome I, Vol. 1 and 2, *review* by Dr. K. Mellanby, 842
Entomology : Annual Review of, Vol. 8 (edited by Ray F. Smith), *review* by H. Oldroyd, 108
Entomology : Radioisotopes and Ionizing Radiations in (International Atomic Energy Agency,) 333
Entomology in Canada : The Centennial of, 232
Entwisle, Dr. A. R. : Appointed lecturer in Metallurgy, 232
"Environmental Monitoring", symposium on, 540
Environmental Temperature preferred by the Young Pig (L. E. Mount), 1212
Enzymes and Drug Action (edited by Dr. J. L. Mongar and A. V. S. de Reuck), Ciba Foundation Symposium, jointly with the Co-ordinating Committee for Symposia on Drug Action, *review* by Dr. G. A. Snow, 418
Enzymes and Structural Genes : Repressors, Cryptic (C. C. Lindegren), 720
Enzymes and their use in Clinical Diagnosis : Multiple Molecular Forms of (Prof. R. J. Wieme), 437
Enzymes in the Silkworm, *Bombyx mori*, to reduce Folate and Sepiapterin : Occurrence of Two Different (M. Matsubara et *al.*), 908
Enzymology, Milstead Laboratory of Chemical, Shell Research, Ltd. (H. Harvey), 427
Eosinophils of the Female Rat : Effects of Lysergic Acid Diethylamide on the Total Leukocytes and (A. M. Sackler et *al.*), 1194
Epidermal Regeneration in the Skin Wounds of Guinea Pigs : Effect of Scabs on the Rate of (M. Zahir), 1013
Epitaxial Oxide Growth on Thin Single-crystal Gold–Nickel Alloy Films (I. H. Khan and M. F. Francombe), 800
Epps, F. J. : The South-Eastern Union of Scientific Societies, Annual Congress, 25
Equatorial F Region : Back-scatter of Radio Waves from the (B. R. Clemesha), 797
Equilibria in Water–Alcohol Mixtures (A. Johnson, B. B. Nilawar and R. H. Peters), 692
Equilibrium Coverage of Copper by Chemisorbed Hydrogen (D. R. Rossington and S. J. Holden), 589
Erb, W., et *al.* : Diurnal Fluctuations in the Numbers of DNA Synthesizing Nuclei in Various Mouse Tissues, 863
Eremoplastron bovis : Carbohydrases of the Rumen Oligotrich (R. W. Bailey and R. T. J. Clarke), 1291
Erlandson, A. L., et *al.* : A New Staphylococcal Antigen, 1074
Ernst, Prof. E. : Biophysics of the Striated Muscle, second edition, *review* by Dr. D. Noble, 1224
Erysiphe graminis DC. in Oats : Physiological Specialization in (J. D. Hayes and W. S. Catling), 1111
Erythrocyte : Hexokinase Activity as a Function of Age of the Human (G. J. Brewer and R. D. Powell), 704
Erythrocytes : Oxidation of Reduced Glutathione by Acetylphenylhydrazine, Hæmoglobin and (Doris Balinsky and R. E. Bernstein), 187
Erythrocytes in Histoincompatible Recipients : Survival of Mouse (G. Möller), 573
Erythrocytes *in vitro* in Various Species : Uptake of Iodothyronines by (A. Slebodziński), 75
Erythropoiesis : Quantitation of (D. Lockner), 390
Erythropoietin by Anoxic Perfusion of the Isolated Kidney of a Dog : Production of (E. O. Zangheri et *al.*), 572
E. coli B/r : Effect of 8-Azaguanine on the Specificity of Antigens synthesized by (G. M. Pontieri and O. J. Plescia), 191
E. coli Ergosomes : Structure and Function of (Dr. T. Staehelin et *al.*), 865
Essen, L. : Basic Concepts of Measurement and the Michelson-Morley Experiment, 684
Esso Magazine, 133
Esterase Activity of *Musca* Homogenates : *In vitro* Effect of Lowering Surface Energy on (H. H. Shatoury), 1192
Estimation of Ruby Laser Oscillation Loss (J. I. Masters), 442
Ethidium Bromide by Exposure of Cells to Hypotonic Media : Alteration of the Biochemical Effects of (T. S. Kandaswamy and J. F. Henderson), 807
2-ethyl-2-phenyl Butyramide of Intrahepatic Cholestasis with Bile Plugs in Dogs : Experimental Production by (C. H. Keysser et *al.*), 498
Ethylene and its Halogeno-derivatives : Ionization Potentials and the Structures of the Photo-ionization Yield Curves of (J. Momigny), 1179
Ethylene by Sub-cellular Particles from Tomatoes as Influenced by Components of the System : Evolution of (Dr. G. Ram chandra et *al.*), 767
Ethylene Production by a Sub-cellular Fraction from Tomatoes : Influence of Temperature and Ageing on (Prof. Mary Spencer and M. Meheriuk), 1077
Ethylene Production of Apples : Effect of Time of Picking on the (B. G. Wilkinson), 715
Euglena gracilis : Linear Relationship between Temperature and Uptake of Oxygen in (D. E. Buetow), 196
Euratom-Information, Vol. 1, No. 1 (May 1963), 857
European Brewery Convention : Report of the Barley Committee : Trials 1961, *review* by A. H. Cook, 525
Evans, C. R., and Bennet-Clark, H. C. : Fragmentation of Patterned Targets when viewed as Prolonged After-images, 1215
Evans, D. E., et *al.* : Spectra of Giant Pulses from a Ruby Laser, 1281
Evans, D. F., and Jones, D. : Infra-red Spectra of some Anhydrous Complex Cyanide Acids, 277
Evans, E., and Delihas, N. : Nucleotide Sequence Investigations in Microsomal Ribonucleic Acids of Normal and Rous Sarcoma Virus-infected Tissues, 488
Evans, Dr. E. A., and Stanford, F. G. : Stability of Thymidine Labelled with Tritium or Carbon-14, 762
Evans, N. T. S., and Naylor, P. F. D. : Polystyrene Membranes for Covering Oxygen Electrodes for Use in Tissue, 911
Evans, Dr. P. E., et *al.* : Education in Materials Science, 233
Evans, W. D., and Elliott, R. B. : Beacon Sandstone : its Petrology and Hydrocarbon Content, 686
Evans, W. H., and Rechcigl, jun., M. : Role of Catalase and Peroxidase in the Metabolism of Leucocytes, 1001
Events associated with Development of Lipid Plaques on Plasma Agar (J. T. Weld and W. M. O'Leary), 510
Evidence for a Humoral Thymus Factor Responsible for the Maturation of Immunological Faculty (Dr. D. Osoba and Dr. J. F. A. P. Miller), 653
Evidence for New Phase occurring in Portland Cements (A. E. Moore), 480
Evidence of the Mechanism of Ouabain Inhibition of Cation Activated Adenosine Triphosphatase (J. S. Charnock and R. L. Post), 910
Evidence that 'Normal Incomplete Cold Antibody' is not a Gamma-globulin (M. Adinolfi, C. Daniels and P. L. Mollison), 389
Evolution : Animal Species and (Ernst Mayr), *review* by Sir Julian Huxley, 838
Evolution of Ethylene by Sub-cellular Particles from Tomatoes as Influenced by Components of the System (Dr. G. Ram chandra, Prof. M. Spencer and M. Meheriuk), 767
Ewes : Effects of Œstrogen on Fertility in (F. H. W. Morley et *al.*), 403
Ewing, M., and Mueller, S. : Synthesis of Normally Dispersed Wave Trains by means of Linear System Theory, 539
Examination of Optically Excited Amino-acids by Electron Spin Resonance at Very Low Temperature (M. Ptak and P. Douzou), 1092
Examination of the Structure of Soil Humic Acids by Pyrolysis–Gas Chromatography (B. R. Nagar), 1213
Excretion of Radiorubidium by Saliva in Rats after Whole-body Irradiation : Changes occurring in the (M. Raković et *al.*), 1008
Exercise : Hæmostatic Changes Associated with (E. Ikkala et *al.*), 459
Exley, K. A., and Collier, B. : Mechanism of the Antagonism by Tetraethylammonium of Neuromuscular Block due to d-Tubocurarine or Calcium Deficiency, 702
Exogenous Substances by Cells : Differences in the Disposition of Endogenous and (A. V. Furano and J. P. Green), 380
Experimental Data bearing on the Role of Liquid Immiscibility in the Genesis of Carbonatites (A. F. Koster van Groos and P. J. Wyllie), 801
Experimental Production of 2-ethyl-2-phenyl Butyramide of Intrahepatic Cholestasis with Bile Plugs in Dogs (C. H. Keysser, J. A. Williams, L. E. Van Petten and N. Coy), 498
Experimental Transovarial Transmission of Kyasanur Forest Disease Virus in *Haemaphysalis spinigera* (K. R. P. Singh, K. Pavri and C. R. Anderson), 513
Explosion in an Autoclave caused by Cellulose Nitrate Tubes (I. H. Silver), 102
Explosives, Liquid, with Transparent Detonation Products (H. D. Mallory and R. A. Plauson), 58
Extremely Low-frequency Radio Propagation in an Inhomogeneous Ionosphere (R. Burman and R. N. Gould), 581
Eye : Barium Content of Different Parts of the Choroid of the Bovine (K. Kostial-Simonovic and A. Pirie), 1007
Effect of Instantaneous Flashes on Adaptation of the (W. A. H. Rushton), 971 ; (J. E. Dowling and R. Hubbard), 972
Physiology of the (Hugh Davson), second edition, *review* by R. A. Weale, 1221
Eye of the Cockroach *Blaberus giganteus* : Effects of X-rays on Electrical Activity in the (W. F. Baldwin et *al.*), 616
Eye of the Rabbit : Effect of Melanocyte-stimulating Hormone on the (K. Dyster-Aas and C. E. T. Krakau), 76
Eyre, Dr. S. R. : Vegetation and Soils, *review* by W. S. Wilson, 631
Eysenck, Prof. H. J. : Biological Basis of Personality. Substance of the Thomas Young Lecture delivered at St. George's Hospital Medical School, June 1963, 1031

FAARVANG, H. J., and Lauritsen, O. S. : Increase of Trypsin Inhibitor in Serum during Pregnancy, 290
Fachini, G., et *al.* : Nemasperm and Pituitary Inhibition, 195
Facilitated Diffusion of Oxygen through Hæmerythrin Solutions (J. B. Wittenberg), 816
Factors Determining the Behaviour of Plant Pathogens in Soil (Dr. N. T. Flentje), 327
Fänge, R., and Krog, J. : Inability of the Kidney of the Hagfish to secrete Phenol Red, 713
Fantola, A. L., et *al.* : Radiation Yield of Citraconic and Mesaconic Acids in Aqueous Solution, 594
Far-infra-red Absorption Spectra of some Complex Halides of Molybdenum and Tungsten (D. M. Adams, H. A. Gebbie and R. D. Peacock), 278
Farberov, A. I., et *al.* : Two Components in the Development of Ray Cataract in Frogs, 1109
Fargie, B., et *al.* : Unlinked Loci affecting Related Biosynthetic Steps in *Pseudomonas aeruginosa*, 926
Faris, S. R. : Reduction of Oxygen at a Carbon Electrode Emerging from an Electrolyte, 754
Farmer, Dr. R. H. : Wood Extractives and Their Significance to the Pulp and Paper Industries, *review*, 732
Fasciola hepatica in Sheep : Critical Testing of Substances against (J. Vodrážka), 96
Fatal Case of Poisoning with Amitriptyline (I. Sunshine and J. Bäumler), 1103
Fats : Carcinogenicity of Preheated (R. S. d. Zaldívar), 1300
Fatty Acid, Branched-chain, of the Preen Gland of the Goose : Incorporation of Propionic Acid into a (R. E. Noble et *al.*), 600
Fatty Acids in Rat Heart and Diaphragm Muscles : Effects of Alloxan Diabetes and Adrenaline on Concentrations of Free (P. B. Garland and P. J. Randle), 381
Fatty Acids within the Vasculature of the Wing of an Unanæsthetized Bat : Biomicroscopic Observations on Vasoconstrictive and Thrombogenic Effects produced by Long-chain Saturated (L. A. Soloff and Mary P. Wiedeman), 495
Fausch, H., et *al.* : Ferulic Acid as a Component of a Glycoprotein from Wheat Flour, 287
Federation of British Industries : *Civil Research Policy : a Report of an F.B.I. Working Party*, 725
Management Education and Training Needs of Industry : a Report by an F.B.I. Working Party, 628, 964
Feedback : Maintenance of High Accuracy without Augmented (J. A. Leonard and R. Conrad), 512
Feeding Behaviour : Foraging and (O. Lowenstein), 966
Feeding Mechanism in the American Wood Stork : The Billsnap Reflex (M. P. Kahl, jun., and L. J. Peacock), 505
Feet : Ipsilateral Confusion in 2-Choice and 4-Choice Responses with the Hands and (K. W. Blyth), 1312
Feinberg, I., et *al.* : 'Dream Time' in Hallucinating and Non-hallucinating Schizophrenic Patients, 1118
Feingold, B. F., et *al.* : Antigenic Activity of Tryptic Peptides of Tobacco Mosaic Virus Protein, 831
Feinstein, A. : Character and Allotypy of an Immune Globulin in Rabbit Colostrum, 1197
Fencl, Dr. Z., and Vintrová, E. : A New Metabolic Regulator : its Stimulation of Citric Acid Production and Anti-sulphonamide and Streptomycin Effect, 905
Ferembach, D. : Frequency of Spina Bifida Occulta in Prehistoric Human Skeletons, 100
Fernández, F. O., et *al.* : Production of Erythropoietin by Anoxic Perfusion of the Isolated Kidney of a Dog, 572
Ferns : Induction of Buds on Older Leaf Primordia in (Dr. Elizabeth G. Cutter and Prof. C. W. Wardlaw), 985
Ferrimagnetics : Microwave Ferrities and (Dr. Benjamin Lax and Kenneth J. Button), *review* by Dr. E. W. Lee, 5
Ferritin and Siderin : Quantitative Relations between (W. Meier-Ruge et *al.*), 175
Ferromagnetismus mit einen Beitrag (Dr. Eckart Kneller, Prof. Dr. Alfred Seeger and Dr. Helmut Kronmüller), *review* by Dr. E. W. Lee, 5
Ferrous Complex : Action Spectrum of Mitotic (Dr. J. E. Amoore), 38
Fertility in Ewes : Effects of Œstrogen on (F. H. W. Morley et *al.*), 403
Ferulic Acid as a Component of a Glycoprotein from Wheat Flour (H. Fausch, W. Kündig and H. Neukom), 287
Fessenden, June M., and Moldave, Prof. K. : Polyuridylic Acid and Aminoacyl Transfer to Mammalian Ribosomes, 1172
Festenstein, H. : Micro-culture of HeLa Cells and Human Embryo Liver on Polythene Disks, 981
Feulgen–Schiff's Technique for Examination of the Distribution of the Intracellular *Rickettsia*-like Micro-organisms in Whole Mounts of Ticks, or their Tissues (M. A. Roshdy), 827
Fibres of Guanine Nucleosides and Nucleotides (J. Iball, C. H. Morgan and H. R. Wilson), 688
Fibrillar and Matrix Proteins in the Formation of Keratin : Separate Synthesis of (A. M. Downes et *al.*), 1059
Fibroblast Cells *in vitro* : Low-voltage Electron Beam Irradiation of Normal and 5-Bromouridine Deoxyriboside-treated *L-P*$_{59}$ Mouse (Dr. A. Cole et *al.*), 780
Field Studies in Education, 311
Field Survey Association Annual Prize, 1963, 1044
Fielder, G. : Terrestrial Oceanic Ridges and Lunar Mare Ridges, 473
Finance of Education (Campaign for Education), 1137
Fincham, Dr. J. R. S., and Day, Dr. P. R. : Fungal Genetics, *review* by Prof. G. Pontecorvo, 417
Fine, B. C., et *al.* : Penetration of Pyrethrin I labelled with Carbon-14 into Susceptible and Pyrethroid Resistant Houseflies, 927
Fine, J., et *al.* : Behaviour of Lysomes in Hæmorrhagic Shock, 493
Finkle, B. S., and Jackson, J. V. : Occurrence of Pseudo-Barbiturates in Post-mortem Material, 1061
Fiocco, G., and Smullin, L. D. : Detection of Scattering Layers in the Upper Atmosphere (60-140 km) by Optical Radar, 1275
Fiore-Donati, L., et *al.* : Influence of Urethane on Susceptibility to Leukæmia Induction by Graffi Virus in Adult Mice, 292
Mast Cell Reaction and 5-Hydroxytryptamine Content in the Skin of Syrian Golden Hamsters painted with 9:10-Dimethyl-1:2-benzanthracene, 293
Fish as Food (edited by G. Borgstrom), Vol. 2, *review* by Dr. G. R. Wadsworth, 731
Fish Behaviour : Electronically Scanned Sonar in the Investigation of (Dr. V. G. Welsby et *al.*), 980
Fish (*Clarias*) : Electric Receptors in a Non-electric (H. W. Lissmann and K. E. Machin), 88
Fisher, M. W., et *al.* : A New Staphylococcal Antigen, 1074
Fisher, R. D., and Haber, H. E. : Chemically Reduced Nickel Substrates for the Development of Uniaxial Anisotropy in Electro-deposited Thin Films, 163
Fishes : A History of (J. R. Norman. Second edition revised by P. H. Greenwood), *review* by Q. Bone, 522
Fitch, F. J., et *al.* : Geochronological Investigations on Rocks from North Wales, 449
Fitzgerald, Dr. M. J. T. : Appointed reader in Anatomy, 1044
Five Co-ordinate Compounds of Cobalt (Dr. A. Earnshaw, P. C. Hewlett and Dr. L. F. Larkworthy), 483
Fixation of Atmospheric Nitrogen by Root Nodules of *Comptonia peregrina* (H. Ziegler and R. Höser), 508
Flavour of Beef and Whale Meat (I. Hornstein, P. F. Crowe and W. L. Sulzbacher), 1252
Flear, Dr. C. T. G., and Florence, Irené : Muscle Biopsy in Man : An Index of Cellular Potassium? 156
Fleet, S. G., and McConnell, J. D. C. : Direct Electron-optical Resolution of Anti-phase Domains in a Silicate, 586
Fleming, J. A. C., and Wiernik, G. : Influence of Fractionation on Clinical Response and Dosage in Radiotherapy, 924
Flentje, Dr. N. T. : Factors Determining the Behaviour of Plant Pathogens in Soil, 327

Flint : Strength and Structure of (R. K. Iler), 1278
Flint, Prof. Richard F., and Longwell, Prof. Chester R. : Introduction to Physical Geology, second edition, *review*, 1125
Flocks, M., et *al.* : Retinal Photocoagulation by Lasers, 146
Florence, Irené, and Flear, Dr. C. T. G. : Muscle Biopsy in Man : An Index of Cellular Potassium? 156
Florentin, J. J. : Applied Dynamic Programming, *review*, 6
Florkin, Prof. Marcel, and Stotz, Prof. Elmer H. (edited by) : Comprehensive Biochemistry, Vols. 1, 3 and 4, *review* by Dr. D. T. Elmore, 311
Florry, Dr. J. S. : Appointed "Glass Manufacturers' Federation" Senior Research Fellow, 748
Flotation : Decontamination of Synthetic Effluent by (R. L. Cardozo and P. Dejonghe), 687
Flour : Ferulic Acid as a Component of a Glycoprotein from Wheat (H. Fausch et *al.*), 287
Flow of Uterine Blood and the Œstrous Cycle (I. J. Kopin and R. J. Wurtman), 386
Flow Study of Polymer Melts using the Instron Rheometer (E. Mary Nicholas), 543
Fluidized Bed : Variation of Bed Height with Bubbling in an Air/Catalyst (J. F. Richardson and L. Davies), 898
Fluorescence Microscopy : Cellular Uptake of Chloramphenicol as revealed by (L. Diamond), 90
Fluorescin and Cytochrome *c* by *Pseudomonas fluorescens* : An Inverse Relationship of the Effects of Oxygen and Iron on the Production of (H. Lenhoff), 601
Fluorocarbons (H. B. Milner), 753
5-Fluorouracil on Regeneration in Tadpoles : Effect of (A. E. Dumont and N. Sohn), 617
Flysch Deposits : Sedimentology of some (Dr. A. H. Bouma), *review* by Dr. J. E. Prentice, 519
Fœtal Myoglobin in the Urine of an Adult (F. L. Benoit, G. B. Theil and R. H. Watten), 387
Fœtal Pulmonary Fluid with Fœtal Plasma and Amniotic Fluid : Comparison of (B. B. Ross), 1100
Fœtus : Perfusion of the Viable Sheep (D. A. Nixon et *al.*), 183
Fog of December 1962 : Atmospheric Hydrogen Sulphide Concentrations During the London (J. T. Minster), 474
Folate and Sepiapterin : Occurrence of Two Different Enzymes in the Silkworm *Bombyx mori*, to reduce (M. Matsubara et *al.*), 908
Foley, W. A., et *al.* : X-ray Inhibition of Urethan-stimulated Proliferation of Lung Cells of the Mouse as Estimated by Incorporation of Tritiated Thymidine, 1267
Follett, B. K., and Heller, H. : Pharmacological Characteristics of Neurohypophysial Hormones in Lungfish and Amphibians, 611
Fonds National de la Recherche Scientifique, Thirty-fifth Annual Report, 960
Fonnum, F., and Haavaldsen, R. : Weever Venom, 286
Food : Fish as (edited by G. Borgstrom), Vol. 2, *review* by Dr. G. R. Wadsworth, 731
Man and his (Sir William Slater. Substance of the Sanderson-Wells lecture, given at the University of London), 1225
Food and Agriculture Organization : *Diseases of Free-Living Wild Animals* (FAO Agricultural Studies No. 57), 121
Freedom from Hunger Campaign–Basic Study No. 11 : Third World Food Survey, 651
Food Colours on Silica Gel : Thin-layer Chromatography of Some (J. F. Barrett and A. J. Ryan), 372
Food for Man and Beast : Providing (Prof. M. Jones), 890
Food Research : Advances in, Vol. 11 (edited by C. O. Chichester, E. M. Mrak and G. F. Stewart), *review* by Dr. Magnus Pyke, 944
Food Science at the University of Leeds (Prof. A. G. Ward), 25
"Food Supply and Nature Conservation", one-day symposium, 1238
Foot-and-Mouth Disease Virus : Purification of Radioactive (Dr. F. Brown and B. Cartwright), 1168
Foraging and Feeding Behaviour (O. Lowenstein), 966
Forearm : A Metabolic Regulating Device based on the Actions of Human Growth Hormone and of Insulin, Singly and Together, on the Human (D. Rabinowitz and K. L. Zierler), 913
Forensic Science Laboratories : World List of (edited by Dr. D. Patterson), *review* by R. A. Outteridge, 317
Forestry in Britain, 644
Formation and Properties of the Black Form of Carbon Disulphide (E. G. Butcher, M. Alsop, J. A. Weston and H. A. Gebbie), 756
Formation of Electrons and of Atomic Hydrogen in γ-irradiated Ice (L. Kevan, P. N. Moorthy and J. J. Weiss), 689
Formation of Extra Nerve-muscle Junctions in Innervated Muscle (R. Miledi), 1191
Formation of Histamine in Ruminal Fluid (J. Sanford), 829
Formation of Stable Shells from Protein Sub-units as a Mode of Virus Synthesis (Prof. G. Belyavin and Dr. E. Rowatt), 949
Formica Polyctena Forst. : Response to Movement by (G. L. Ayre), 405
Forrest, Dr. J. S. : High-voltage Insulation, 883
Forrest, M. J., et *al.* : Spectra of Giant Pulses from a Ruby Laser, 1281
Fossil Dinoflagellates from Upper Triassic Sediments (Dr. W. A. S. Sarjeant), 353
Foster, J. F., and Craig, T. (edited by) : Commonwealth Universities Yearbook 1963, *review*, 316
Foundations of Statistical Inference : A Discussion Opened by Prof. L. J. Savage, *review* by M. C. Pike, 630
Fourdeux, Mlle. A., and Wronski, A. : Twinning at 77° K of 'Flash-annealed' Niobium, 1284
Fowden, Dr. L., et *al.* : Effect of 3,4-Dehydro-DL-Proline on Growth and Protein Synthesis, 35
Fowler, J. F. : A Fast-neutron Source for Radiotherapy, 923
Fowler, J. F., et *al.* : Dose-effect Relationships for Radiation Damage to Organized Tissues, 253
Fragmentation of Patterned Targets when viewed a Prolonged After-images (H. C. Bennet-Clark and C. R. Evans), 1215

Francis, Prof. John : Rutherford and the Atom : Poetic Portrayal of a Scientific Discovery, 1028
Veterinary Science at Brisbane, 964
Francombe, M. F., and Khan, I. H. : Epitaxial Oxide Growth on Thin Single-crystal Gold-Nickel Alloy Films, 800
Frasson, E., *et al.* : Binding of the Thiocyanate Ion in Complexes with a Palladium-(II)-containing Tertiary Phosphines, 803
Chain Structure of the *Cyclo*pentadienils of Monovalent Indium and Thallium, 1087
Frattali, V., *et al.* : Reduction and Reoxidation of the Disulphide Bonds of Pepsinogen, 1186
Free Radicals (Dr. B. A. Thrush), 750
Free Radicals : The sixth International Symposium held in July 1963, 750
Freedom from Hunger Campaign : Combating Deficiencies of Protein, 651
Freeman, E. S., and Anderson, D. A. : Physical Transitions of the Alkali Metal Nitrates as Revealed by Differential Thermal Analysis, 63
Freeman, E. S., and Zirkind, P. : Electrical Conductivity of Ammonium Perchlorate, 1280
Freeman, F. M., and Heseltine, W. W. : Absorption of Chlorhydroxyquinoline, 703
Freeze-drying : Homograft Antigens : Isolation of Fractions of Normal Cells which retain Activity after (L. T. Mann, jun., *et al.*), 499
Freeze-drying and Radiation Protection (A. M. Cook, T. A. Roberts and Jean P. Widdowson), 194
Frequency Drift and Time Profile of 200 Mc/s Bursts of Type III and the Electron Temperature of the Corona (O. Elgarøy and H. Rødberg), 268
Frequency of Spina Bifida Occulta in Prehistoric Human Skeletons (Denise Ferembach), 100
Frey-Wyssling, Prof. A. : Elected foreign member The Royal Society, Edinburgh, 119
Friedhoff, Prof. A. J., and van Winkle, E. : Conversion of Dopamine to 3,4-Dimethoxyphenylacetic Acid in Schizophrenic Patients, 1271
3,4-Dimethoxyphenylethylamine and Other Amines in the Urine of Schizophrenic Patients, 204
Friedlander, H. Z., *et al.* : Electron Spin Resonance Spectra in Various Clay Minerals, 61
Friedman, H. : Persistence of Antigen in Nucleoprotein Fractions of Mouse Spleen Cells during Antibody Formation, 502
Frink, C. R., *et al.* : Electron Spin Resonance Spectra in Various Clay Minerals, 61
Frith, Dr. R. : Proceedings of the First International Symposium on Rocket and Satellite Meteorology, 1962, *review*, 729
Frogs : Two Components in the Development of Ray Cataract in (V. V. Popov *et al.*), 1109
Frölén, H., *et al.* : Genetic Effects of Strontium-90 on Immature Germ-cells in Mice, 303
Fruit : Use of Paper Impregnated with Esters of *O*-phenylphenol to Reduce the Rotting of Stored (Dr. R. G. Tomkins), 669
Fruit Juices : Sub-commission formed for the Standardization of the Chemical Analysis of Fruit Juices by the International Federation of Fruit Juice Producers, 434
Frydman, R. B., and Hassid, W. Z. : Biosynthesis of Sucrose with Sugar Cane Leaf Preparations, 382
Fuel Technology : Dr. E. Rothwell appointed lecturer in, 232
Fuels : Reprocessing for Irradiated (J. M. Fletcher), 542
Fukuta, N. : Ice Nucleation by Metaldehyde, 475
Fullman, B. : Stereochemical Theory of Olfaction, 912
Fulton, J. S., *et al.* : Commonwealth Universities Congress, 1963, 1127
Functional Coupling Between Cells in the Visual Cortex of the Unrestrained Cat (J. S. Griffith and G. Horn), 876
Functional Polyovuly in the Sei Whale *Balaenoptera borealis* Lesson (P. B. Best and J. L. Bannister), 89
Functional Vascular Fields in the Pituitary Stalk of the Mouse (Dr. W. C. Worthington, jun.), 461
Fundamental Extension of Einstein's Diffusion–Mobility Relationship (E. R. Pike), 994
"Fundamental Processes in Radiation Chemistry", general discussion on, 334
Fundamentals of Semiconductor and Tube Electronics (Prof. H. Alex Romanowitz), *review* by Dr. A. A. Shepherd, 734
Funderburk, jun., H. H., and Lawrence, J. M. : Sensitive Method for Determination of Low Concentrations of Diquat and Paraquat, 1011
Fungal Genetics (Dr. J. R. S. Fincham and Dr. P. R. Day), *review* by Prof. G. Pontecorvo, 417
Fungistatic Effect of Streptomycin : Mode of Action of Selective (J. Vörös), 1110
Furano, A. V., and Green, J. P. : Differences in the Disposition of Endogenous and Exogenous Substances by Cells, 380
Further Education for School Leavers, booklet, 538
Further Separation of Iodine, Monolodotyrosine and Diiodotyrosine by means of Modified Charcoal (I. Posner and E. Pimentel), 177
Future of the Aeroplane in the Civil and Military Fields (Dr. S. G. Hooker), 886

GABOR, T., and Stickler, R. : Chemical Etching Studies and Transmission Electron Microscopy of Silicon Carbide, 1054
Gaby, Prof. W. L., and McCurley, Eleanor H. : Nitrogenous Components of Phospholipids extracted from *Penicillium chrysogenum*, 1187
Gadebusch, H. H. : Immunization against *Cryptococcus neoformans* by Capsular Polysaccharide, 710
Gahne, Bo : Genetic Variation of Phosphatase in Cattle Serum, 305
Gajdos, A., and Gajdos-Török, M. : Inhibitory Action of Adenine, Adenine Nucleosides and Nucleotides on the Biosynthesis of Porphyrins by *Rhodopseudomonas spheriodes*, 1093
Gajdos-Török, M., and Gajdos, A. : Inhibitory Action of Adenine, Adenine Nucleosides and Nucleotides on the Biosynthesis of Porphyrins by *Rhodopseudomonas spheriodes*, 1093
D-galactoside 6-bromhydrin : Structure of α-methyl (B. Sheldrick and J. M. Robertson), 1086
Galaxy and the Magellanic Clouds (B. J. Robinson), 322
Gale, Prof. E. F. : Amino Acid Pools : Proceedings of a Symposium on Free Amino Acids, *review*, 1124
Gallium (III) and Indium (III) Iodides and Alkyl Iodides : Effect of Electron Donors on the Isotopic Exchange between Aluminium (III) (A. Polaczek and A. Halpern), 1286
Electrical Conductivity of Solutions of Aluminium (III) (A. Halpern and A. Polaczek), 1286
Gallium Antimony System : Pressure Temperature Projection of the Three-phase Line of the (J. C. Brice and M. J. King), 897
Gallium Arsenide Lasers : Time Characteristics of Light Pulses from (J. Lytollis *et al.*), 1083
Gallium as Negative Electrode in Galvanic Cells : Possible Use of (D. Jahn and H. G. Plust), 806
Gallium in Substituted Yttrium Iron Garnets : A Non-Destructive Radioanalytical Method for the Determination of (J. P. Cali *et al.*), 1081
Galvanic Cells : Possible Use of Gallium as Negative Electrode in (D. Jahn and H. G. Plust), 806
Ganguly, P., *et al.* : Sedimentation Characteristics of the Human Hæmoglobins A, F and E, 919
Garden Flowers (R. D. Meikle), *review* by B. L. Burtt, 314
Gardner, F. F., *et al.* : A Radio Source with a Very Unusual Spectrum, 682
Gardner, W. E., *et al.* : Anhydrous Ruthenium Chlorides, 1089
Garland, P. B., and Randle, P. J. : Effects of Alloxan Diabetes and Adrenaline on Concentrations of Free Fatty Acids in Rat Heart and Diaphragm Muscles, 381
Garnaud, Jean-Claude (edited by): Advances in Horticultural Science and Their Applications : Proceedings of the XVth International Horticultural Congress, Nice 1958. Vols. 2 and 3, *review* by G. P. Harris, 3
Garriock, W. : Modification of the Weather, 1241
Gas : Total Trapping of Chromatographic Effluents in Argon Carrier (Dr. P. A. T. Swoboda), 31
Gas Chromatographic Columns lined with a Porous Layer : Height Equivalent to a Theoretical Plate of Tubular (M. J. E. Golay), 370
Gas Chromatography (Dr. Howard Purnell), *review* by Dr. C. S. G. Phillips, 210
Gas Chromatography : Determination of *n*-Alkanes in Mixtures of Saturated Hydrocarbons by Means of (P. A. Schenck and E. Elsma), 170
Examination of the Structure of Soil Humic Acids by Pyrolysis– (B. R. Nagar), 1213
In situ treatment of Kieselguhr for (E. P. Atkinson and G. A. P. Tuey), 482
Gas Chromatography and Electron Affinity Spectrometry : High-sensitivity Detection of Amino-Acids by (Dr. R. A. Lansdowne and Prof. S. R. Lipsky), 141
Gas Vacuole of the Rhizopod Protozoan, *Arcella* : Oxygen in the (Anna Cicak *et al.*), 983
Gaseous Phase : Reaction of Phenoxy Radicals with Methyl Radicals in the (M. F. R. Mulcahy and D. J. Williams), 761
Gases by Glow under Pressure through Porous Membranes : Separation of (S. Sourirajan), 590
Gases on Heated Solids : Measurement of Thermal Accommodation of (L. G. Carpenter *et al.*), 164
Gaskill, jun., H. S., *et al.* : Periodic (Liesegang) Precipitation of Chemicals, 623
Gass, G. H., *et al.* : Reduction by Chlorpromazine of Pylorus-ligation Ulcers in the Rat, 1296
Gastric Instillation of 9,10-Dimethyl-1,2-Benzanthracene with Subsequent Local Continuous Exposure to 'Tween 40' : A Stochastic Model of Carcinogenesis compared with Mouse Skin Tumour, Enhancement after (E. E. Niskanen and N. Arley), 83
Gastric Ulceration in the Guinea Pig : Degraded Garrageenan and Experimental Acute (W. Anderson and P. D. Soman), 389
Gastropods stained by the Novikoff Reaction for Thiamine Pyrophosphatase : Capillary Plexuses in (O. L. Thomas), 89
Gattani, M. L. : Systemic or Semi-systemic Infection of Wheat and *Puccinia graminis tritici*, 398
Gaudiano, A., *et al.* : Nemasperm and Pituitary Inhibition, 195
Gawron, O. : A Hypothesis linking the Succinic Dehydrogenase System to an Intermediate of Oxidative Phosphorylation, 377
Gebbie, H. A., *et al.* : Far-infra-red Absorption Spectra of some Complex Halides of Molybdenum and Tungsten, 278
Formation and Properties of the Black Form of Carbon Disulphide, 756
Gebbie, K. B., and Seaton, M. J. : Model Atmospheres for Central Stars of Planetary Nebulæ, 580
Geiger, L. E., *et al.* : Medullary Vagal Effects of *d*-Lysergic Acid Diethylamide in the Decerebrate Cat, 700
Gelboin, H. V., and Loeb, L. A. : Stimulation of Amino-acid Incorporation by Nuclear Ribonucleic Acid from Normal and Methylcholanthrene-treated Rats, 809
Gene Frequencies in Yugoslav Population : Study of Several (P. Grünwald and C. Herman), 830
Gene Function : Histones and (G. C. Barr and Prof. J. A. V. Butler), 1170
"General Theory of Electrical Machines" vacation course on, 435
Generalization of the Phase-law of Lunar Geomagnetic Tides (Dr. O. Schneider), 548
"Generation, Detection and Properties of Coherent Radiation of Wave-length Less than One Millimetre" conference on, 748
Genes : Repressors, Cryptic Enzymes and Structural (C. C. Lindegren), 720
Genetic and Developmental Studies of a Quantitative Character (S. G. Spickett), 870
Genetic Assimilation of Behaviour : A Possible Case of (Dr. N. Moray and K. Connolly), 358
Genetic Basis of Stem Rust Resistance in Wheat (F. X. Laubscher), 719
Genetic Effects of Strontium-90 on Immature Germ-cells in Mice (K. G. Lüning, H. Frölén, A. Nelson and C. Rönnbäck), 303
Genetic Variation of Phosphatase in Cattle Serum (Bo Gahne), 305
Genetics : An Introduction to (Prof. A. H. Sturtevant and Prof. G. W. Beadle), *review* by Dr. K. S. Dodds, 734
Prof. D. G. Catcheside appointed to the chair of, 536
Outline of Human (Prof. L. S. Penrose), *review* by Dr. C. A. Clarke, 730
"Genetics and Physiology of Bacterial Viruses", Course on, 435
Gentner, W., and Zähringer, J. : Radiogenic and Atmospheric Argon Content of Tektites, 583
Genus of Brackish-water Oligochæta New to Britain (R. O. Brinkhurst), 1206
Geochronological Investigations on Rocks from North Wales (F. J. Fitch, Dr. J. A. Miller and M. Y. Meneisy), 449
Geography : Prof. K. F. Hare appointed to the chair of, 435
Geological Society of America : Presidential Address, 105
Geology : Introduction to Physical (Prof. Chester R. Longwell and Prof. Richard F. Flint), second edition, *review*, 1125
Geology and Geochronology of the Seychelles Islands and Structure of the Floor of the Arabian Sea (B. H. Baker and Dr. J. A. Miller), 346
Geology of Moor House : A National Nature Reserve in North-East Westmorland (Dr. G. A. L. Johnson), *review* by S. E. Hollingworth, 941
Geology of the North-Central Part of the Arctic Archipelago, North-West Territories (Y. O. Fortier *et al.*), 1043
Geomagnetic Fields : Distinguishing between the Solar, the Interplanetary and (K. D. Cole), 897
Geomagnetic Tides : A Generalization of the Phase-law of Lunar (Dr. O. Schneider), 548
Geometrical Optics, 753
Geophysical Research : Radio and International (Dr. R. L. Smith-Rose), 11
Geopotential : Tesseral Harmonics in the (Imre G. Izsak), 137
George, J. D. : Behavioural Differences between the Larval Stages of *Cirriformia tentaculata* (Montagu) from Drake's Island (Plymouth Sound) and from Southampton Water, 195
Germ-cells in Mice : Genetic Effects of Strontium-90 on Immature (K. G. Lüning *et al.*), 303

German Society of Polar Research : Meeting to be held October 1963, 748, 1238
Gerraughty, R. J., et *al.* : Isolation of Alkaloids using Ultrasonic Energy, 1292
Getoff, N. : Ultrasonic Effect on Neutron-Irradiated Inorganic Solid Compounds, 593
Gibberellin on Varietal Identity in Red Clover (*Trifolium pratense* L.) : Effect of (Dr. J. L. Stoddart), 1270
Gibberellins : A Barley Endosperm Bioassay for (P. B. Nicholls and L. G. Paleg), 823
Gibson, Dr. A. F., and Hooper, J. E. N. : The Royal Radar Establishment, 227
Gibson, R. H. : Electrical Stimulation of Pain and Touch Systems, 307
Gigantism-inducing Factors in *Chlorella pyrenoidosa* (M. Rodriguez-López), 506
Gilbert, Dr. C. : *Obituary* of Prof. G. R. Goldsbrough, 428
Gilbert, G. A., and Jenkins, R. C. Ll. : Analysis of Reversibly Intereacting Systems by Differential Boundaries in Electrophoretic and Sedimentation Experiments, 688
Gilden, R. V., and Rosenquist, G. L. : Duration of Antibody Response to Soluble Antigen, 87
Giles, N. H., and Partridge, C. W. H. : Sedimentation Behaviour of Adenylsuccinase formed by Interallelic Complementation in *Neurospora crassa*, 305
Gillespie, Dr. J. S. : Appointed to a Head Research Fellowship, 230
Gillman, Dr. T. : An Introduction to Comparative Pathology, *review*, 4
Ginger, C. D. : Isolation and Characterization of Muramic Acid from two Spirochætes : *Borrelia duttoni* and *Leptospira biflexa*, 159
Ginoza, Dr. W. : Radiosensitive Molecular Weight of Single-stranded Virus Nucleic Acids, 453
Girdler, Dr. R. W. : Tectonics, *review*, 520
Gitlin, D., et *al.* : A Crystalline Fragment from Human Gamma-globulin, 284
Glaciers : Norwegian (G. De Q. Robin), 966
Glagov, S., and Wolinsky, H. : Aortic Wall as a 'Two-phase' Material, 606
Glasgow's Royal College : New Developments at (Dr. S. C. Curran), 843
Glass at Elevated Temperatures : Dissolution of (G. Butler and J. C. K. Ison), 998
Glass Manufacturers' Federation Senior Research Fellowship, 748
Glasses : Solvated Electrons in Alkali (M. J. Blandamer et *al.*), 902
Glatt, Dr. M. M. : Alcoholic Addiction : A Psycho-social Approach to Abnormal Drinking, *review*, 1023
Glauconites from Proterozoic Sediments, Northern Territory, Australia : Retention of Radiogenic Argon in (A. W. Webb et *al.*), 270
Glencoe Ignimbrites : Source of the (J. L. Roberts), 901
Glenert, J., et *al.* : Intestinal Degradation of Gamma-globulin in the Dog, 1096
Glick, Dr. S. M., et *al.* : Immunoassay of Human Growth Hormone in Plasma, 784
Gamma-globulin : A Crystalline Fragment from Human (E. J. Hershgold et *al.*), 284
Evidence that 'Normal Incomplete Cold Antibody, is not a (M. Adinolfi et *al.*), 389
Gamma-Globulin Variability : A Genetic Hypothesis (Dr. O. Smithies), 1231
α_2-Globulin after Interference with the Liver : Appearance of Slow (W. G. Heim and J. M. Kerrigan), 1100
Globulin in Rabbit Colostrum : Character and Allotypy of an Immune (A. Feinstein), 1197
Gamma-globulin in the Dog : Intestinal Degradation of (S. B. Andersen et *al.*), 1096
γ-Globulin Molecules Genetically Defined at Two Loci : Distribution of Allotypic Specificities among Rabbit (Dr. S. Dray et *al.*), 52
Glomerular Lesions resembling those Toxæmia of Pregnancy by Thromboplastin Infusion in Rabbits : Production of Ultra-structural (P. Vassalli et *al.*), 1105
Gloor, P. : Identification of Inhibitory Neurones in the Hippocampus, 699
D-Glucono-γ and δ-Lactone : Transformation and Hydrolysis of (T. Takahashi and M. Mitsumoto), 765
Glucose, Anorexic Effect of Intraperitoneal, in the Hypothalamic Hyperphagic Cat (M. Russek and P. J. Morgane), 1004
Glutathione by Acetylphenylhydrazine, Hæmoglobin and Erythrocytes : Oxidation of Reduced (Doris Balinsky and R. E. Bernstein), 187
Glycerol-Extracted Muscle : Partial Reversibility of the Ca''-ITP-Contraction of (Prof. W. Kuhn et *al.*), 1154
Glycoprotein from Wheat Flour : Ferulic Acid as a Component of a (H. Fausch et *al.*), 287
Glycosidase Abnormality in Synovial Membrane in Joint Disease (N. G. C. Hendry and A. J. Carr), 392
Glycoside : A Synthetic Cyclitol (K. A. Caldwell et *al.*), 374
Godin, P. J., et *al.* : Penetration of Pyrethrin I labelled with Carbon-14 into Susceptible and Pyrethroid Resistant Houseflies, 927
Godwin, H. : Isostatic Recovery in Scotland, 1277
Goering, Harvey L., and Willardson, Robert K. (edited by) : Compound Semiconductors, Vol. I, *review* by Dr. A. A. Shepherd, 946
Goggin, P. R. : Some Effects of Electron Irradiation on the Young's Modulus of Graphite, 367
Goguel, Prof. Jean : Tectonics, *review* by Dr. R. W. Girdler, 520
Golay, M. J. E. : Height Equivalent to a Theoretical Plate of Tubular Gas Chromatographic Columns lined with a Porous Layer, 370
Gold and of Silver in Solution by Atomic Absorption Spectroscopy : Determination of (M. C. Greaves), 552
Gold–Nickel Alloy Films : Epitaxial Oxide Growth on Thin Single-Crystal (I. H. Khan and M. F. Francombe), 800
Goldberg, A., and Rimington, Prof. C. : Diseases of Porphyrin Metabolism, *review* by Prof. C. H. Gray, 1222
Goldberg, Dr. I. H., et *al.* : Inhibition of Ribonucleic Acid-Polymerase Reactions by Actinomycin and Proflavine, 44
Goldie, Dr. A. W. : Appointed to the chair of Pure Mathematics, 434, 852
Goldman, S. C., and Horowitz, S. : Riometer Observations of Ionospheric Absorption due to the Solar Flares of April 15, 1963, 1147
Goldsbrough, Prof. G. R. : *Obituary* by Dr. C. Gilbert, 428
Goldstein, J. L., et *al.* : Accumulation of Amino-acids in Plant Cell Tissue Cultures, 1302
Goldsworthy, Dr. F. A. : Appointed to the chair of Applied Mathematics, 434
Golichenkov, V. A., et *al.* : Two Components in the Development of Ray Cataract in Frogs, 1109
Goodey, Dr. T. (second edition, revised and rewritten) : Soil and Freshwater Nematodes, *review* by Dr. J. W. Seinhorst, 523
Goodman, H. M., and Rich, Prof. A. : Mechanism of Polyribosome Action during Protein Synthesis, 318

Growth and Nucleation of the $\beta \rightarrow \alpha$ Transformation in Uranium 0.45 per cent Chromium Alloy (A. Bar-Or, P. Wynblatt and G. Hirsch), 585
'Growth Hormone-prolactin' : Evidence for a Human Chorionic (J. J. Sciarra et *al.*), 1005
Growth Hormone Serum within the Human Placenta : Localization of Anti-human : (J. J. Sciarra et *al.*), 1005
Growth in Size in Mammals : Regulation of (Dr. J. M. Tanner), Substance of a portion of the first Harold E. Jones Memorial Lecture, April 1963, 845
Grubb, P. W., et *al.* : Mechanisms for Oxidative Phosphorylation at the Pyridine Nucleotide/Flavoprotein Level, 759
Grumbach, M. M., et *al.* : Localization of Anti-human Growth Hormone Serum within the Human Placenta : Evidence for a Human Chorionic 'Growth Hormone-prolactin', 1005
Grünwald, P., and Herman, C. : Study of Several Gene Frequencies in Yugoslav Population, 830
Guanidine on Picornavirus Reproduction : Synergistic Effect of 2-(α-Hydroxybenzyl)-benzimidazole and (H. J. Eggers and I. Tamm), 513
Guanine Nucleosides and Nucleotides : Fibres of (J. Iball et *al.*), 688
Guggenheim International Astronautics 1963 Award, 331
Guinea Pigs : Effect of Scabs on the Rate of Epidermal Regeneration in the Skin Wounds of (M. Zahir), 1013
Guli, E., and Edwards, J. H. : Meiotic Investigations in Man, 1114
Gunning, Dr. B. E. S., and Barkley, W. K. : Kinin-induced Directed Transport and Senescence in Detached Oat Leaves, 262
Gunsalus, I. C., and Stanier, Roger Y (edited by) : The Bacteria : A Treatise on Structure and Function, Vol. 3, *review* by Dr. L. B. Quesnel, 4
Gupta, Prof. K. M. : Marsilae : Botanical Monograph No. 2, *review* by Dr. J. D. Lovis, 1224
Guthrie, Douglas : *A Short History of the Royal Society Club of Edinburgh* 1820 to 1962, 856
Gynaecology and Obstetrics : A Textbook of (Douglas G. Wilson Clyne), *review* by Dr. J. Murray, 1224

HAAVALDSEN, R., and Fonnum, F. : Weever Venom, 286
Haber, H. E., and Fisher, R. D. : Chemically Reduced Nickel Substrates for the Development of Uniaxial Anisotropy in Electro-deposited Thin Films, 163
Habowsky, J. E. J., et *al.* : Effects of X-rays on Electrical Activity in the Eye of the Cockroach *Blaberus giganteus*, 616
Haemaphysalis spinigera : Experimental Transovarial Transmission of Kyasanur Forest Disease Virus in (K. R. P. Singh et *al.*), 513

Hæmerythrin Solutions : Facilitated Diffusion of Oxygen through (J. B. Wittenberg), 816
Hæmochromatosis : Wine as Source of Iron in (R. A. MacDonald), 922
Hæmoglobin : Structure of (H. Muirhead and Dr. M. F. Perutz), 633
Hæmoglobin H. : A Preliminary X-ray Analysis of (Dr. M. F. Perutz and L. Mazzarella), 639
Hæmoglobin H in Leukæmia : Occurrence of (G. H. Beaven *et al.*), 1297
Hæmoglobin after Freezing and Thawing : Behaviour of Mammalian (S. Squires and Dr. J. A. McFadzean), 783
Hæmoglobin and Erythrocytes : Oxidation of Reduced Glutathione by Acetylphenylhydrazine (Doris Balinsky and R. E. Bernstein), 187
Hæmoglobins A, F and E : Sedimentation Characteristics of the Human (P. Ganguly *et al.*), 919
Hæmoglobins of Two Elephant Shrews (J. Buettner-Janusch and V. Buettner-Janusch), 918
Hæmolytically Active 11 S Component of Rabbit, Guinea Pig and Human Serum by means of Antigen-Antibody Precipitates : Demonstration of a (J. F. Barbaro), 819
Hæmorrhagic Shock : Behaviour of Lysomes in (L. Bitensky *et al.*), 493
Hæmostatic Changes Associated with Exercise (E. Ikkala, G. Myllylä and H. S. S. Sarajas), 459
Hafez, Prof. E. S. E. (edited by) : The Behaviour of Domestic Animals, *review* by Dr. W. H. Thorpe, 522
Hafnium : New Proton-containing Oxides of Titanium, Zirconium and (F. K. McTaggart), 339
Hagfish to secrete Phenol Red : Inability of the Kidney of the (R. Fänge and J. Krog), 713
Haimson, J., and Brodie, I. : High-current Cathode for Electron Linear Accelerator, 795
Hales, C. N. : Appointed to a Stothert Research Fellowship, 230
Halides of Molybdenum and Tungsten : Far-infra-red Absorption Spectra of some Complex (D. M. Adams *et al.*), 278
Hall, A. C. : Stimulated Compton Scattering of Electrons by Standing Waves of Light, 683
Hall, A. E., and Noble, D. : Transient Responses of Purkinje Fibres to Non-uniform Currents, 1294
Hall, J. W., and Rase, H. F. : Dislocations and Catalysis, 585
Halley Bay : Joule Heating of the Ionosphere over (K. D. Cole), 444
Halloysite in Kyushu : Age of the Youngest Hydrated (S. Aomine and N. Miyauchi), 1311
Hallsworth, Prof. E. G. : Appointed to CSIRO, 1237
Hallucinating and Non-hallucinating Schizophrenic Patients : 'Dream Time' in (R. L. Koresko *et al.*), 1118
Halo Substituents on the Homolytic Dissociation of Dibenzyl Hyponitrites : Effect of Alkyl and (J. B. De Sousa), 64
Halogenonitrobenzamides : Anti-coccidial Activity of (S. J. Ball and E. W. Parnell), 612
Halpern, A., and Polaczek, A. : Effect of Electron Donors on the Isotopic Exchange between Aluminium (III), Gallium (III) and Indium (III) Iodides and Alkyl Iodides, 1286
Electrical Conductivity of Solutions of Aluminium (III), Gallium (III) and Indium (III) Iodides in Alkyl Iodides, 1286
Hamster Cells in Culture : Variations in X-ray Response During the Division Cycle of Partially Synchronized Chinese (W. K. Sinclair and R. A. Morton), 1158
Hancock, Dr. G. J. : Appointed reader in Aeronautical Engineering, 24
Handley Page Memorial Lecture (Duke of Edinburgh), 627
Hands and Feet : Ipsilateral Confusion in 2-Choice and 4-Choice Responses with the (K. W. Blyth), 1312
Haner, B. A., *et al.* : Molecular Geometry of 7a-Bromocholesteryl Chloride, 1180
Hanessian, S., and Haskell, T. H. : A New Staphylococcal Antigen, 1075
Hapten-Protein Conjugates : Use of Oxidized Proteins in the Examination of Immunochemical Specificity in Delayed Hypersensitivity to (S. Leskowitz), 85
Haptens : Delayed Hypersensitivity to a Conjugate of Polytyrosine and its Inhibition by (S. Leskowitz), 291
Haptoglobin Typing using Acrylamid Gels : Micro Method of (A. Baumgarten), 490
Hardy, T. L., *et al.* : A New Approach to Studying the Protein-binding Properties of Penicillins, 758
Hare, Prof. F. K. : Appointed to the Chair of Geography, 435

Hydrogen–Air Fuel Cell with Homogeneous Oxidation Catalyst Redox Cycle (A. Dravnieks), 1182
Hydrogen Bond Formation Plus ATP-Dependent Extensions of Part of the Myosin-Actin Cross-Bridges : Calcium-Dependent Contractions with (Prof. R. E. Davies), 1068
Hydrogen Chloride Gas on RNA and its Component Nucleotides : Reaction of (M. E. Bramwell), 811
Hydrogen Sulphide Concentrations During the London Fog of December 1962 : Atmospheric (J. T. Minster), 474
Hydrolysis : A Comparison of the Disaccharides obtained from Human Blood-group A, B, H and Le^a Substances by Partial Acid (Dr. T. H. Painter et *al.*), 569
'Hydrophobic Binding Site' : Specificity of Pepsin and its Dependence on a Possible (J. Tang), 1094
Hydrostatic Extrusion (D. Green, S. W. Pigott, K. Slater and P. Daniels), 485
Hydrothermal Veins : Reverse and Normal Remanent Magnetization in (M. Krs), 365
N-Hydroxy-2-acetamidofluorene and Hormonal Stimulation : Rapid Liver Tumour Induction by Concerted Action of (S. R. Pai et *al.*), 1299
N-hydroxy-4-acetylaminostilbene : Carcinogenic Action of (R. W. Baldwin et *al.*), 613
2-(*α*-Hydroxybenzyl)-benzimidazole and Guanidine on Picornavirus Reproduction: Synergistic Effect of (H. J. Eggers and I. Tamm), 513
γ-Hydroxyhomoarginine, in *Lathyrus* : A New Amino-acid (E. A. Bell), 70
Hydroxylation of Phenoxyacetic Acid by Stem Tissue of *Avena sativa* (E. W. Thomas, B. C. Loughman and R. G. Powell), 73
5-Hydroxytryptamine Content in the Skin of Syrian Golden Hamsters painted with 9:10-Dimethyl-1:2-benzanthracene : Mast Cell Reaction and (L. Chieco-Bianchi et *al.*), 293
5-Hydroxytryptamine in the Spermatophoric Sac of the Octopus (Dr. T. Mann), 1066
Hyman, J. M., et *al.* : Trisomy of Autosome 16, 404
Hypersensitivity, Delayed, to a Conjugate of Polytyrosine and its Inhibition by Haptens (S. Leskowitz), 291
Hypothesis linking the Succinic Dehydrogenase System to an Intermediate of Oxidative Phosphorylation (O. Gawron), 377
Hypotonic Media : Alteration of the Biochemical Effects of Ethidium Bromide by Exposure of Cells to (T. S. Kandaswamy and J. F. Henderson), 807

IBALL, J., et *al.* : Fibres of Guanine Nucleosides and Nucleotides, 688
Ice : Energy of Formation of D-Defects in (D. Eisenberg and C. A. Coulson), 368
Formation of Electrons and of Atomic Hydrogen in *γ*-irradiated (L. Kevan et *al.*), 689
Ice-fall : Velocity of Sliding of an (G. Shinoda), 165
Ice Nucleation by Metaldehyde (N. Fukuta), 475
Identification of a Somatic Antigen of *Staphylococcus aereus* Critical for Phagocytosis by Human Blood Leucocytes (S. Mudd, A. Yoshida, I. W. Li and N. A. Lenhart), 1200

Identification of Inhibitory Neurones in the Hippocampus (P. Gloor), 699; (P. Andersen, J. C. Eccles and Y. Løyning), 699
Ignimbrites : Source of the Glencoe (J. L. Roberts), 901
Ikeda, R. M., *et al.* : Mechanism of Solanesol Breakdown During Pyrolysis, 661
Ikkala, E., *et al.* : Hæmostatic Changes Associated with Exercise, 459
Iler, R. K. : Strength and Structure of Flint, 1278
Immune Response : Behaviour of Active Bacterial Antigens during the Induction of the (G. L. Ada *et al.*), 1257; (G. J. V. Nossal *et al.*), 1259
Immunity : Resemblances between Passive Anaphylactic Sensitization and Transmission of Passive (Prof. F. W. R. Brambell), 1164
Immunization against *Cryptococcus neoformans* by Capsular Polysaccharide (H. H. Gadebusch), 710
Immunoassay of Human Growth Hormone in Plasma (Dr. S. M. Glick, Dr. J. Roth, Dr. R. S. Yalow and Dr. S. A. Berson), 784
Immunochemical Specificity in Delayed Hypersensitivity to Hapten-Protein Conjugates : Use of Oxidized Proteins in the Examination of (S. Leskowitz), 85
Immunoelectrophoresis of Sweat Proteins (M. Jirka and J. Masopust), 283
Immunofluorescence : Species Identification of Animal Cell Strains by (W. F. Simpson and C. S. Stulberg), 616
Immunoglobulin Abnormalities of the Thymectomized Rat (B. G. Arnason, C. de Vaux St. Cyr and P. Grabar), 1199
Immunological Competence of Thymus Cells after Transfer to Thymectomized Recipients (R. B. Taylor), 873
Immunological Faculty : Evidence for a Humoral Thymus Factor Responsible for the Maturation of (Dr. D. Osoba and Dr. J. F. A. P. Miller), 653
Immunological Reactivity of Bursaless Chickens in Graft Versus Host Reactions (Noel L. Warner and A. Szenberg), 43
Immunological Tolerance to Normal Mouse Tissue : Preparation of an Antiserum Specific to a Spontaneous Mouse Leukæmia after the Induction of Artificial (E. Levi), 501
Imperial College of Science and Technology : Blackett, Prof. P. M. S. retires from Physics Department, 22
Butler, Prof. C. C. appointed head of the Physics Department, 22
Inaugural Lectures, 1960-62, 1042
Implications of Similarity in Rare-earth Fractionation of Nakhlitic Meteorites and Terrestrial Basalts (Dr. R. A. Schmitt and R. H. Smith), 550
Importance of Mixing Sequence when using Set-retarding Agents with Portland Cement (G. M. Bruere), 32
In the Service of Science, Information and the Enjoyment of Leisure, 850
Inability of the Kidney of the Hagfish to secrete Phenol Red (R. Fänge and J. Krog), 713
Incidence of Pseudocholinesterase Variants in Australian Aborigines (W. R. Horsfall, H. Lehmann and Daphne Davies), 1115
Incidence, Size and Shape of Meta-cortex Fibres in Wool (J. Marcet and W. J. Onions), 1306
Incorporation of 5-Iodo-2′-deoxyuridine into the Deoxyribonucleic Acid of Vaccina Virus (W. H. Prusoff *et al.*), 1310
Incorporation of Propionic Acid into a Branched-chain Fatty Acid of the Preen Gland of the Goose (R. E. Noble *et al.*), 600
Indenter : Reversed Plastic Flow during the Unloading of a Spherical (K. L. Johnson), 1282
India : University Grants Commission and Ministry of Education Vice-Chancellors' Conference, 1962, 650
Indian Water Buffaloes with Reagents for Antigenic Factors of Cattle : Blood-typing of (S. P. Datta and W. H. Stone), 1208
Indians : Selection Intensity in Brazilian Caingang (F. M. Salzano), 514
Indium and Thallium : Chain Structure of the *Cyclo*pentadienils of Monovalent (E. Frasson *et al.*), 1087
Indium (III) Iodides and Alkyl Iodides : Effect of Electron Donors on the Isotopic Exchange between Aluminium (III), Gallium (III) and (A. Polaczek and A. Halpern), 1286
Electrical Conductivity of Solutions of Aluminium (III), Gallium (III) and (A. Halpern and A. Polaczek), 1286
Indolyl-3-acetic Acid : Quantitative Spectrophotometric Determination of (R. A. Fletcher and S. Zalik), 903
Reversal of Gamma-ray-induced Susceptibility to Decay of Potato Tubers and Tomato Fruit by Methyl Ester of (P. B. Mathur), 1007
Induction of Buds on Older Leaf Primordia in Ferns (Dr. Elizabeth G. Cutter and Prof. C. W. Wardlaw), 985
Induction of Melanotic Lesions of the Iris in Rats by Urethane given during the Neonatal Period (F. J. C. Roe *et al.*), 1201
Induction of Mutations and Killing of Cells in Irradiated Spermatogonia of *Drosophila* (P. Oftedal), 1301
Induction of Mutations in Barley with Ultra-violet Radiation (A. T. Natarajan and S. Nirula), 822
Induction of Tumours of the Stomach in Rats and Mice by *N*-nitroso-*N*-alkylurethanes (R. Schoental), 190
Industrial Pest Control Association : Officers for 1963-64, 122
Industrial Research in Britain, 963
Industrial Research in Britain : Organizing Scientific and, 207
Industry : Management Education and Training Needs of, a Report by an F.B.I. Working Party, 628
Industry and Social Policy : Science (Kenneth Denbigh), *review* by R. Brightman, 418
Infection of Celery Seedlings by Viable Spores of *Septoria* spp. (J. E. Sheridan), 508
Infertility in Mice caused by Nutritional Stress before Mating (T. J. McClure), 504
Infiltration of Intra-abdominal Organs by Ascites Tumours (D. N. Wheatley, E. J. Ambrose and G. C. Easty), 188
Influence of Bacillus Calmette-Guérin Infection on the Intensity of Homograft Reaction in Rats (R. Vitale and N. Allegretti), 507
Influence of Calcium Phosphate on the Absorption of Radioactive Strontium (R. S. Bruce), 1107
Influence of Crystal Defects on the Annealing of Chemical Radiation Damage (S. R. Mohanty and S. R. Upadhyay), 169
Influence of 2,4-Dinitrophenol on Anion Transport by an Intestinal *in vitro* Preparation (V. Capraro, E. Milla and A. Bianchi), 1099
Influence of Electrode Coatings on Conduction Currents in Transformer Oil (M. C. Cullingford, A. A. Zaky, M. E. Zein Eldine and R. Hawley), 1082
Influence of Fractionation on Clinical Response and Dosage in Radiotherapy (J. A. C. Fleming and G. Wiernik), 924
Influence of Isolated Components of the Uterine Secretion of Phagocytosis (Jean Killingbeck, Dr. N. B. Haynes and Dr. G. E. Lamming), 255
Influence of Light on the Biosynthesis of Bacteriochlorophyll by Rhodopseudomonas spheroides (G. Drews and K. Jaeger), 1112
Influence of Mechanical Damage on Opaline Silica Deposition in *Molinia caerulea* L. (D. W. Parry and Dr. F. Smithson), 925
Influence of Stroboscopic Illumination on the After-effect of Seen Movement (S. M. Anstis, R. L. Gregory, N. de M. Rudolf and D. M. MacKay), 99
Influence of Temperature and Ageing on Ethylene Production by a Sub-cellular Fraction from Tomatoes (Prof. Mary Spencer and M. Meheriuk), 1077
Influence of Temperature and Medium on the X-ray Sensitivities of Leukæmia Cells *in vitro* (J. Z. Beer, J. T. Lett and P. Alexander), 193
Influence of Testosterone and Polyuridylic Acid on the Incorporation of Phenylalanine into Peptide Linkage by Prostatic Ribosomes (D. A. Silverman, S. Liao and H. G. Williams-Ashman), 808
Influenza Virus : Synthesis of Viral Ribonucleic Acid by a Chemically Inactivated (C. Scholtissek and R. Rott), 200
Influenza Virus *In ovo* : A Molecular Approach to Teratogenesis : Effect of Vitamin A on (Dr. H. A. Blough), 33
Information *Per se* (Dr. P. S. Henshaw), 1050
Infra-red Spectra of some Anhydrous Complex Cyanide Acids (D. Jones and D. F. Evans), 277
Ingram, B. J., *et al.* : X-ray Inhibition of Urethan-stimulated Proliferation of Lung Cells of the Mouse as Estimated by Incorporation of Tritiated Thymidine, 1267
Inhibition of Biological Synthesis of Acetylcholine by Triethylcholine (G. Bull and B. A. Hemsworth), 487
Inhibition of 6-Mercaptopurine-resistant Cancer Cells in Culture by *Bis*(Thioinosine)-5′,5‴-Phosphate (J. A. Montgomery, G. J. Dixon, E. A. Dulmage, H. J. Thomas, R. W. Brockman and H. E. Skipper), 769
Inhibition of Ribonucleic Acid-Polymerase Reactions by Actinomycin and Proflavine (Dr. I. H. Goldberg, Dr. E. Reich and Dr. M. Rabinowitz), 44
Inhibition of Thyroid Function by a Dithiocarbamoylhydrazine (M. I. Tulloch, J. Crooks and P. S. Brown), 288
Inhibitory Synapses on Somas of Purkinje Cells in the Cerebellum (Dr. P. Andersen, Sir John Eccles and Dr. P. E. Voorhoeve), 655
Inhomogeneous Problems in Elasticity or Heat Conduction (Prof. H. S. Heaps), 477
Innervated Muscle : Formation of Extra Nerve-muscle Junctions in (R. Miledi), 1191
Inorganic Chemistry : Progress in, Vol. 4 (edited by F. Albert Cotton), *review* by Dr. I. R. Beattie, 734
Inorganic Chemistry : Dr. F. G. A. Stone appointed to the chair of, 744
Inouye, A., *et al.* : Sedimentation Constant-Molecular Weight Relation of Ribosomes, 1290
"Insect Reproduction", Symposium at the Royal Entomological Society, 748
Insecticide Resistance in the Cocoa Capsid, *Distantiella theobroma* (Dist.), (J. A. Dunn), 1207
Insecticides in French People : Storage of (W. J. Hayes, jun., *et al.*), 1189
Insects : Structure of the Brain of (H. Jawłowski), 302
Synthesis of an Aromatic Ring in (P. C. J. Brunet), 492
In situ Treatment of Kieselguhr for Gas Chromatography (E. P. Atkinson and G. A. P. Tuey), 482
Inspection of Alkali and Cement Works, 751
Institute for Scientific Information, Philadelphia : Dr. J. O'Connor appointed research associate, 122
Institute of Personnel Management : Conference on "Management, Productivity and Industrial Relations", 855
Institute of Physics and the Physical Society : Conference on "Some Aspects of Surface Behaviour", 435
1964 and 1965 Exhibition of Scientific Instruments and Apparatus, 1238
Institute of Radio Engineers : Awards, 1043
Institute of Tropical Meteorology at Poona, 1042
Institution of Chemical Engineers : First Conference on "Education in Materials Science" (L. Holliday *et al.*), 233
Institution of Electrical Engineers : Conference on "The Design and Use of Microwave Valves", 962
Electronics Division. Convention on H.F. Communication, March 1963 (Long-distance Radio Communication at High-frequencies, R. L. Smith-Rose), 545
Officers for 1963-64, 1043
Instron Rheometer : Flow Study of Polymer Melts using the (E. Mary Nicholas), 543
Instrument, A New, for Atmospheric Ozone (D. I. Wardle), 1177
Instrument Design : Manufacture and Use (S. Weintroub), 648
Insulating Liquids : Effect of Some Organic Additives on Conduction Current and Breakdown of (L. Angerer), 62
Insulin A Chain Derivative with an Intact Intra-chain Disulphide Bond : Preparation of an (J. Meienhofer and O. Brinkhof), 1095
Insulin, Singly and Together, on the Human Forearm : A Metabolic Regulating Device based on the Actions of Human Growth Hormone, and of (D. Rabinowitz and K. L. Zierler), 913
Integration of Cell Reactions (Dr. A. C. R. Dean and Sir Cyril Hinshelwood), 7
Intellectual Tradition : Science and the, 105
Interaction of Chromatid Breaks induced by Three Different Radiomimetic Compounds (A. Michaelis and R. Rieger), 1014
Interaction of Methyl-substituted Borazines with Various Acceptor Molecules (E. K. Mellon, jun., and J. J. Lagowski), 997
Interaction of Vaccinia Virus and Cells in Primary and Continuous Culture (M. Nishmi and H. Niecikowski), 1117
Interference Experiments relating to whether Tobacco Mosaic Virus and Cucumber Viruses 3 and 4 are Strains of the same Virus (Jia-Hsi Wu and S. G. Wildman), 1015
Intermediary Metabolism in Bull Semen (W. J. W. Hines and M. J. H. Smith), 179
Intermittent Germination of *Capsella* (Sir Edward Salisbury), 1303
International Association of Forensic Toxicologists : Formation of, 334
International Astronomical Union Symposium No. 20 (The Galaxy and the Magellanic Clouds, B. J. Robinson), 322
International Atomic Energy Agency : *Radioisitopes and Ionizing Radiations in Entomology*, 333
Research Contract Awarded to the Lovanium University at Leopoldville, 853
Research Laboratories Director appointed, 230
International Atomic Energy Agency and Trieste Centre for Theoretical Physics, 22
International Commission on Radiological Units and Measurements : *Radiobiological Dosimetry*, 1139
International Epizootics Bureau, Report for 1961-62 (W. A. Pool), 336
International Federation of Fruit Juice Producers : Sub-commission formed for the Standardization of the Chemical Analyses of Fruit Juices, 434
International Laboratory of Genetics and Biophysics course on "The Genetics and Physiology of Bacterial Viruses", 435
International Phycological Society : Fifth International Seaweed Symposium to be held, 645
International Scientific Radio Union : Fourteenth General Assembly (Dr. R. L. Smith-Rose), 436
International Society of Biometeorology : Proceedings of the Second International Bioclimatological Congress, London, 1960 (edited by S. W. Tromp), *review* by L. P. Smith, 413
International Union of Crystallography, sixth meeting, 232
International Union of Geodesy and Geophysics : Thirteenth general assembly, 24
Interplanetary and Geomagnetic Fields : Distinguishing between the Solar, the (K. D. Cole), 897
Interplanetary Magnetic Field (Prof. V. A. Bailey), 1029
Interplanetary Magnetic Fields as a Cause of Comet Tails (D. B. Beard and M. P. Nakada), 580

Interstitial Solid Solutions in Body-centred Cube Metals (Dr. J. Stringer and A. R. Rosenfield), 337
Intervertebral Disk : Calcification in the (T. K. F. Taylor and K. Little), 612
Intestinal Absorption : Quantitative Aspects of Pinocytosis in Relation to (D. S. Parsons), 1192
Intestinal Degradation of Gamma-globulin in the Dog (S. B. Andersen *et al.*), 1096
Intestinal *in vitro* Preparation : Influence of 2,4-Dinitrophenol on Anion Transport of an (V. Capraro *et al.*), 1099
Intestinal Tract : Absorption of Chymotrypsin from the (B. L. Kabacoff *et al.*), 815
Intestine : Solute and Water Absorption by the Human Small (Dr. H. P. Schedl and Dr. J. A. Clifton), 1264
Intestine in Organ Culture : Effect of Puromycin on Cholinesterase Activity of Embryonic Chick (A. Burkhalter), 598
Intestine of a Marine Teleost : Sodium and Water Transport across Isolated (C. R. House and K. Green), 1293
Intra-abdominal Organs by Ascites Tumours : Infiltration of (D. N. Wheatley *et al.*), 188
Intra-cardiac Postganglionic Fibres : Selective Stimulation of (B. Lewartowski), 76
Intracellular *Rickettsia*-like Micro-organisms in Whole Mounts of Ticks, or their Tissues : (M. A. Roshdy), 827
Intrahepatic Cholestasis with Bile Plugs in Dogs : Experimental Production by 2-ethyl-2-phenyl Butyramide of (C. H. Keysser *et al.*), 498
Intra-uterine Life : Resuscitation of Sheep Embryos and the Simulation of (A. W. Marrable), 97
Introduction to Comparative Philosophy (P. T. Raju), *review* by F. I. G. Rawlins, 519
Introduction to Genetics (Prof. A. H. Sturtevant and Prof. G. W. Beadle), *review* by Dr. K. S. Dodds, 734
Introduction to Physical Geology (Prof. Chester R. Longwell and Prof. Richard F. Flint), second edition, *review*, 1125
Invertebrates : Laminarinases in Soil and Litter (C. O. Nielsen), 1001
Investment in Man (Sir Eric Ashby), 877
Investment in Science Through Man, 835
In vitro Cytotoxic effect of Isoantibody Measured as Isotope Release from Labelled Target Cell DNA (Prof. G. Klein and Dr. P. Perlmann), 451
In vitro Effect of Lowering Surface Energy on Esterase Activity of *Musca* Homogenates (H. H. Shatoury), 1192
In vivo Degradation of Histamine-adenine Dinucleotide Phosphate to Histamine Ribonucleoside (S. G. A. Alivisatos, A. A. Abdel-Latif, F. Ungar and G. A. Mourkides), 907
In vivo Investigation of the Removal of Trace Elements from Nucleic Acids of Yeast by Ionizing Radiation (H. Altmann, G. Stehlik and K. Kaindl), 823
Iodides : Electrical Conductivity of Solutions of Aluminium (III), Gallium (III) and Indium (III) Iodides in Alkyl (A. Halpern and A. Polaczek), 1286
Iodine-131 : British Standard of Radioactive (W. J. Callow), 898
Iodine-131 in Milk : A Rapid Method for Estimation of (H. Smith and E. L. Whitehead), 503
Iodine-131 using Iodine Monochloride : Simple Preparation of 5-Iodo-2'-deoxyuridine labelled with (A. D. Brownstone), 1285
Iodine Monochloride : Simple Preparation of 5-Iodo-2'-deoxyuridine labelled with Iodine-131 using (A. D. Brownstone), 1285
Iodine, Monoiodotyrosine and Diiodotyrosine by means of Modified Charcoal : Further Separation of (I. Posner and E. Pimentel), 177
5-Iodo-2'-deoxyuridine into the Deoxyribonucleic Acid of Vaccina Virus : Incorporation of (W. H. Prusoff *et al.*), 1310
5-Iodo-2'-deoxyuridine labelled with Iodine-131 using Iodine Monochloride : Simple Preparation of (A. D. Brownstone), 1285
Iodothyronines by Erythrocytes *in vitro* in Various Species : Uptake of (A. Ślebodziński), 75
Iodotyrosines from the Plasma of the Rat : Absence of Free (S. Lissitzky *et al.*), 1002
Ion Exchange Theory of Coagulation (Prof. M. Mirnik), 555
Ion Molecule Reactions in Alkanes : Energetics of (Dr. L. Kevan), 562
Ion Specific Polymer Membrane (R. Bloch, O. Kedem and D. Vofsi), 802
Ionization Potentials and the Structures of the Photo-ionization Yield Curves of Ethylene and its Halogeno-derivatives (J. Momigny), 1179
Ionizing Radiations : *In vivo* Investigation of the Removal of Trace Elements from Nucleic Acids of Yeast by (H. Altmann *et al.*), 823
Ionizing Radiation in Aqueous Media : Behaviour of Polarons produced by the Action of (J. J. Weiss), 589
Ionosphere : Extremely Low-frequency Radio Propagation in an Inhomogeneous, (R. Burman and R. N. Gould), 581
Proceedings of the International Conference on the, *review* by Dr. R. L. Smith-Rose, 728
Ionosphere over Halley Bay : Joule Heating of the (K. D. Cole), 444
Ionospheric Absorption due to the Solar Flares of April 15, 1963 : Riometer Observations of (S. Horowitz and S. C. Goldman), 1147
Ionospheric Effects Due to the Earth's Orbital Position (Dr. G. Noci), 968
Ionospheric Radio Monograph on : XIIIth General Assembly of URSI, London 1960 (edited by W. J. G. Beynon), *review* by J. A. Ratcliffe, 940
Ions : Pre-ionization Phenomena in the Appearance of Some Polyatomic Molecular (J. Momigny), 805
Ions, Light, of Kilovolt Energy : Decomposition of Alkali Metal Nitrates by (S. R. Logan), 369 ; *erratum*, 1238
Ipsilateral Confusion in 2-Choice and 4-Choice Responses with the Hands and Feet (K. W. Blyth), 1312
Ireland : Historical Geology of (Prof. J. K. Charlesworth), *review* by J. C. Brindley, 941
Iris in Rats by Urethane given during the Neonatal Period : Induction of Melanotic Lesions of the (F. J. C. Roe *et al.*), 1201
Iron : Reducing Agents and Absorption of (S. Pollack *et al.*), 384
Iron in Hæmochromatosis : Wine as Source of (R. A. MacDonald), 922
Iron on the Production of Fluorescin and Cytochrome *c* by *Pseudomonas fluorescens*: An Inverse Relationship of the Effects of Oxygen and (H. Lenhoff), 601
Irradiated Fuels : Reprocessing for (J. M. Fletcher), 542
Irradiation : Changes occurring in the Excretion of Radiorubidium by Saliva in Rats after Whole-body (M. Rakovič *et al.*), 1008
Irradiation Damage to Polythene : Temperature Dependence of (G. Todd and G. A. Wild), 172
Irving, Prof. H. : *The Three Cultures*, 627
Isoantibody Measured as Isotope Release from Labelled Target Cell DNA : *In vitro* Cytotoxic effect of (Prof. G. Klein and Dr. P. Perlmann), 451
Isocyanates : Structure of Silyl and Methyl Azides and (J. W. Linnett), 168
Isolation and Characterization of Muramic Acid from two Spirochætes : *Borrelia duttoni* and *Leptospira biflexa* (C. D. Ginger), 159
Isolation of Alkaloids using Ultrasonic Energy (A. E. DeMaggio, J. A. Lott and R. J. Gerraughty), 1292
Isolation of Phosvitin from the Plasma of the Œstrogenized Immature Pullet (Dr. P. J. Heald and P. M. McLachlan), 487
Isolation of a Sialic Acid-rich Glycoprotein Fraction from Normal Human Urine (I. Berggård), 174
Isolation of Two Serologically Active Trisaccharides from Human Blood-group B Substance (T. J. Painter, Winifred M. Watkins and W. T. J. Morgan), 282
Isomerization of 1,2-dichloroethylene induced by Chlorodifluoromethyl Radicals : Formation of Metastable Radicals (H. Derbyshire and C. R. Patrick), 68
Isomers of Hexasulphur Diimide (H. G. Heal), 371
Ison, H. C. K., and Butler, G. : Dissolution of Glass at Elevated Temperatures, 998
Isopodes Terrestres, Deuxième Partie (Prof. Albert Vandel), (Faune de France, Vol. 66), *review* by Dr. E. M. Sheppard, 6
Isostatic Recovery in Scotland (D. F. W. Baden-Powell), 546, 1278
(H. Godwin), 1277
Isotope Release from Labelled Target Cell DNA : *In vitro* Cytotoxic effect of Isoantibody Measured as (Prof. G. Klein and Dr. P. Perlmann), 451
Isotopes of Oxygen (YEDA Research and Development Co.), 433
Isotopic Age Measurements, New, from the McMurdo Sound Area Antarctica (W. C. Pearn, E. E. Angino and D. Stewart), 685
Isotopic Exchange between Aluminium (III), Gallium (III) and Indium (III) Iodides and Alkyl Iodides : Effect of Electron Donors on the (A. Polaczek and A. Halpern), 1286
Iversen, R. T. S., *et al.* : An Indication of Underwater Sound Production by Squid, 250
Ivimey-Cook, Dr. R. B.: The Development of British Heathlands and Their Soils, *review*, 315
Ivy : Tissue Cultures of Juvenile and Adult Specimens of (V. T. Stoutemyer and O. K. Britt), 397
Iyengar, K. S., and Hasan, M. M. : Size and Growth of Cavitation Bubble Nuclei, 995
Izsak, Imre, G. : Tesseral Harmonics in the Geopotential, 137

Jackson, C., *et al.* : Electron Spin Resonance in Polymer Carbons : Effect of Halogens and Interhalogen Compounds, 1090
Jackson, J. V., and Finkel, B. S. : Occurrence of Pseudo-Barbiturates in Post-mortem Material, 1061
Jacobs, T. H. : Surface Charge Density and Sorption of Water Vapour on Lithium Kaolinite, 481
Jaeger, K., and Drews, G. : Influence of Light on the Biosynthesis of Bacteriochlorophyll by *Rhodopseudomonas spheroides*, 1112
Jago, M., *et al.* : Production of a Cephalosporinase by *Pseudomonas pyocyanea*, 375
Jahn, D., and Plust, H. G. : Possible Use of Gallium as Negative Electrode in Galvanic Cells, 806
Jain, S. K., and Suneson, C. A. : Male Sterility for Increased Outbreeding in Populations of Barley, 407
James, Dr. D. G., *et al.* : Commonwealth Universities Congress, 1963, 1127
James, I. M. (edited by) : The Mathematical Works of J. H. C. Whitehead, Vols. 1-4, *review* by Sir William Hodge, 938
James, Prof. T. Campbell : *Obituary* of Prof. J. J. Sudborough, 1136
Jane, Prof. F. W. : *Obituary* by Dr. M. A. P. Madge, 329
Jarman, Dr. G. M. : Appointed lecturer in Zoology, 434
Jarrett, I. G. : Asia and Oceania Congress of Endocrinology, 858
Jawłowski, H. : Structure of the Brain of Insects, 302
Jay, K. E. B. : Modern Physics : An Introduction to Atomic and Nuclear Physics, *review*, 6
Jeffery, P. G., *et al.* : Composition of Montan Wax, 171
Jelínek, R., and Klika, E. : Minute Structure of the Inner Surface of an Embryonic Central Nervous System, 394
Jenkins, D. J., *et al.* : Use of Complex Ions in the Efficiency Tracing Methods for the Standardization of Pure Beta-emitting Nuclides, 368

Measurement of Radio Sources at Centimetre Wavelengths (R. G. Conway), 1177
Measurement of Thermal Accommodation of Gases Heated on Solids (L. G. Carpenter, D. E. Humphries and W. N. Mair), 164
Measurements of Standard Frequency Transmissions, 854
Meat : Flavour of Beef and Whale (I. Harnstein *et al.*), 1252
Meat Research Workers : The ninth conference on the European, September 1963, 232
Mechanical Engineering : H. Billet appointed reader in, 1044
Mechanism of Polyribosome Action during Protein Synthesis (H. M. Goodman and Prof. A. Rich), 318
Mechanism of Rejection of Homotransplanted Kidneys (Dr. S. L. Kountz, M. A. Williams, Dr. P. L. Williams, Dr. C. Kapros and W. J. Dempster), 257
Mechanism of Solanesol Breakdown During Pyrolysis, (J. D. Grossman, R. M. Ikeda, E. J. Deszyck and A. Bavley), 661
Mechanism of the Antagonism by Tetraethylammonium of Neuromuscular Block due to *d*-Tubocurarine or Calcium Deficiency (B. Collier and K. A. Exley), 702
Mechanisms for Oxidative Phosphorylation at the Pyridine Nucleotide/Flavoprotein Level (Dr. J. A. Barltrop, P. W. Grubb and B. Hesp), 759
"Medical Electronics", fifth international conference on, 122
Medical Photography and Cinematography, The Second International Congress of, 1140
Medical Research Council : Abnormal Hæmoglobin Research Unit, 1140
Medical School : Television in the (edited by Charles Engel and John Ellis), 854
Medizinische Biochemie (Dr. S. M. Rapoport), *review* by Dr. S. L. Tompsett, 943
Medullary Vagal Effects of *d*-Lysergic Acid Diethylamide in the Decerebrate Cat (P. Cervoni, J. R. Bertino and L. E. Geiger), 700
Meetham, Dr. A. R. : Apparatus Drawings Project (30 Drawings), *review*, 414
Meheriuk, M., *et al.* : Evolution of Ethylene by Sub-cellular Particles from Tomatoes as influenced by Components of the System, 767
Meheriuk, M., and Spencer, Prof. Mary : Influence of Temperature and Ageing on the Ethylene Production by a Sub-cellular Fraction from Tomatoes, 1077
Meienhofer, J., and Brinkhof, O. : Preparation of an Insulin A Chain Derivative with an Intact Intra-chain Disulphide Bond, 1095
Meier, R. M., *et al.* : Sex Differences in the Serum Cholesterol Response to Stress in Monkeys, 812
Meier-Ruge, W., *et al.* : Quantitative Relations between Ferritin and Siderin, 175
Meikle, R. D. : Garden Flowers, *review* by B. L. Burtt, 314
Meiotic Investigations in Man (J. H. Edwards and E. Gull), 1114
Melanocyte-stimulating Hormone on the Eye of the Rabbit : Effect of (K. Dyster-Aas and C. E. T. Krakau), 76
Melanotic Lesions of the Iris in Rats by Urethane given during the Neonatal Period : Induction of (F. J. C. Roe *et al.*), 1201
Meldola Medal Award, 1140
Mellanby, Dr. K. : Entomologie Appliquée à l'Agriculture, Vols. 1 and 2, *review*, 842
Mellon, jun., E. K., and Lagowski, J. J. : Interaction of Methyl-substituted Borazines with Various Acceptor Molecules, 997
Melville, Sir Harry : The Effects of Federal Programs on Higher Education, *review*, 837
Membrane : Cæsium–Choline Interaction on Muscle (A. Portela *et al.*), 815
Membrane Stability and Salt Tolerance in Gram-negative Bacteria (A. D. Brown and H. P. Turner), 301
Menegus, F., *et al.* : Chain Structure of the *Cyclo*pentadienils of Monovalent Indium and Thallium, 1087
Meneisy, M. Y., *et al.* : Geochronological Investigations on Rocks from North Wales, 449
Mer, Dr. C. L., and Causton, D. R. : Carbon Dioxide : A Factor Influencing Cell Division, 360
6-Mercaptopurine 'Duazomycin A' : Enhanced Suppression of the Secondary Immune Response by Combination of (S. Rosenberg and P. Calabresi), 1101
6-Mercaptopurine-resistant Cancer Cells in Culture by *Bis*(Thioinosine(-5',5'''-Phosphate : Inhibition of (J. A. Montgomery *et al.*), 769
Mercer, S. J., and Booth, G. H. : Resistance to Copper of some Oxidizing and Reducing Bacteria, 622
Mercier, D., *et al.* : Incorporation of Propionic Acid into a Branched-chain Fatty Acid of the Preen Gland of the Goose, 600
Mercuration of Diazomethane (A. N. Wright, K. A. W. Kramer and G. Steel), 903
Mercuric Chloride on Strained Keratin : Action of (J. L. Hoare and J. B. Speakman), 1091
Meridian : Alignment of Cirrus Clouds along the Magnetic (L. Kellner), 900
Meromyosin : Effect of Ultrasonics on the Adenosine Triphosphatase Activity and Actin-binding Ability of L-Myosin and Heavy (M. Bárány *et al.*), 694
Merrett, M. J., and Sunderland, D. W. : Nicotinamide-adenine Dinucleotides, Adenosine Diphosphate and Adenosine Triphosphate Content of Tissues infected by Tobacco Mosaic Virus, 1116

Mesaconic Acids in Aqueous Solution : Radiation Yield of Citraconic and (A. L. Fantola et *al.*), 594
Mesomorphic and Crystalline States in Polyvinyl Chloride by X-ray Diffraction (Dr. M. Mammi and Dr. V. Nardi), 247
Mesozoic Flora, A New, from Tico, Santa Cruz Province, Argentina (S. Archangelsky. *Bulletin of the British Museum (Natural History) : Geology*, 8, No. 2, *review* by T. M. Harris, 418
Meta-cortes Fibres in Wool : Incidence, Size and Shape of (J. Marcet and W. J. Onions), 1306
Metabolic Regulating Device based on the Actions of Human Growth Hormone and of Insulin, Singly and Together, on the Human Forearm (D. Rabinowitz and K. L. Zierler), 913
Metabolic Regulator, a New: its Stimulation of Citric Acid Production and Anti-sulphonamide and Streptomycin Effect (Dr. Z. Fencl and E. Vintrová), 905
"Metabolism and Physiological Significance of Lipids", conference on, 334
Metabolism of Endogenous Substrate in the Retina (H. W. Reading), 817
"Metabolism of Protozoa", Meeting, 962
Metaldehyde : Ice Nucleation by (N. Fukuta), 475
Metal Films in Relation to the Determination of Surface Area and the Nature of Adsorbed Carbon Monoxide : Adsorption of Krypton and Xenon on Evaporated (D. Brennan *et al.*), 1152
Metal Liquid, Heat Transfer in Packed Beds (N. Standish), 1284
Metallurgy : Dr. A. R. Entwisle appointed lecturer in, 232
Metallurgy in Archaeology (Dr. R. F. Tylecote), *review* by Prof. F. C. Thompson, 1223
Metals : Interstitial Solid Solutions in Body-centred Cube (Dr. J. Stringer and A. R. Rosenfield), 337
Metcalfe, Dr. C. R. : Das Tropische Parenchym, A. : Assimilationsgewebe (Handbuch der Pflanzenanatomie, Bd. IV, Teil 7A), *review*, 108
Meteorite : A Magnetized Artificial (Prof. C. M. Carmichael), 426
Meteorites and Terrestrial Basalts : Implications of Similarity in Rare-earth Fractionation of Nakhlitic (Dr. R. A. Schmitt and R. H. Smith), 550
Meteorology : Proceedings of the First International Symposium on Rocket and Satellite (edited by H. Wexler and J. E. Caskey, jun.), *review* by Dr. R. Firth, 729
Methæmoglobin in Red Cells of Human Blood Smears : Elution Procedure for the Demonstration of (E. Kleihauer and K. Betke), 1196
Methane : Temperature of Shocked Argon and (C. E. Reynolds and L. B. Seely), 341
Methionine in Liver of the Chick : Effect of Orotic Acid on the Synthesis of Citrovorum Factor and of (G. Moruzzi *et al.*), 695
Methyl Azides and Isocyanates : Structure of Silyl and (J. W. Linnett), 168
6-Methylaminopurine Content : Possible Turnover of DNA with an Increased (E. C. Theil and S. Zamenhof), 599
Methylcellulose-induced Regression of this Tumour in Rats : Successful Re-introduction of the Murphy-Sturm Lymphosarcoma after (Dr. A. W. Lazard and Diane E. C. Lazar), 48
Methylcholanthrene-treated Rats : Stimulation of Amino-acid Incorporation by Nuclear Ribonucleic Acid from Normal and (L. A. Loeb and H. V. Gelboin), 809
Methyl Ester of Indolyl-3-Acetic Acid : Reversal of Gamma-ray-induced Susceptibility to Decay of Potato Tubers and Tomato Fruit by (P. B. Mathur), 1007
α-methyl D-galactoside 6-bromhydrin : Structure of (B. Sheldrick and J. H. Robertson), 1086
Methyl Glucopyranosides : Rates of Acid Hydrolysis of 2-substituted (R. D. Marshall), 998
Methyl-substituted Borazines with Various Acceptor Molecules : Interaction of (E. K. Mellon, jun., and J. J. Lagowski), 997
Metmyoglobin and Nicotinamide Adenine Dinucleotide Phosphate by Illuminated Chloroplasts : Pathway of Reduction of (Dr. H. E. Davenport), 151
Meyer, Prof. Dr. Fritz Jürgen : Das Tropische Parenchym, A : Assimilationsgewebe (Handbuch der Pflanzenanatomie, Bd. IV, Teil 7A), *review* by Dr. C. R. Metcalfe, 108
Meyer, H. O. A., and Milledge, H. J. : Doped Synthetic Diamonds–Anomalous X-ray Spikes Along < 111 >, 167
Mice : Development of Alcohol Preference in *BALB/c* (R. Kakihana and G. E. McClearn), 511
Michael, C. A., et *al.* : Use of Ear Chamber with Uterine Muscle Transplant to differentiate Myometrial and Vascular Activity, 399
Michael, Dr. D. H. : Appointed to a readership in applied mathematics, 435
Michaelis, A., and Rieger, R. : Interaction of Chromatid Breaks induced by Three Different Radiomimetic Compounds, 1014
Michelson-Morley Experiment : Basic Concepts of Measurement and the (L. Essen), 684
Micro Method of Haptoglobin Typing using Acrylamid Gels (A. Baumgarten), 490
Microbial Classification, 333
Microbial Degradation of Cephalosporin *C*. (A. L. Demain, R. B. Walton, J. F. Newkirk and I. M. Miller), 909
Microbiological Dehydroxylation of Cholic Acid (S. Hayakawa and the late K. Kurokawa), 490
Microbiologists in Underdeveloped Countries, Role of, 333
Microbiology : Annual Review of, Vol. 16 (edited by Charles E. Clifton), *review* by Dr. A. Newton, 733
Prof. B. A. D. Stocker appointed to the Guinness chair of, 536
Microbiology of Antarctic Sea-Ice (J. S. Bunt), 1254
Microchemical Techniques : Proceedings of the International Symposium on (edited by Nicholas D. Cheronis), *review* by Dr. D. T. Lewis, 945
Micro-culture of HeLa Cells and Human Embryo Liver on Polythrene Disks (H. Festenstein), 981
Microdensitometry : Differences in the Utilization of Tritiated Leucine by Single Neurones in Normal and Exercised Rats : An Autoradiographic Investigation with (Dr. J. Altman), 777
Micro-injection of Trypsin into Axons of Squid (E. Rojas and M. Luxoro), 78
Microneurones : Thalamic (T. McLardy), 820
Micro-organisms in Whole Mounts of Ticks, or their Tissues : Feulgen-Schiff's Technique for Examination of the Distribution of the Intracellular *Rickettsia*-like (M. A. Roshdy), 827
Micropalæontology : Principles of Zoological. Vol. I (Dr. Vladimir Pokorny), *review* by Dr. D. D. Bayliss, 942
Microscopic Pore Diameters : Preparation of Sieves with (W. H. Dobelle and R. K. Witt), 1288
Microscopy : Cellular Uptake of Chloramphenicol as revealed by Fluorescence (L. Diamond), 90
Microscopy for the Mineralogical Analysis of Samples of Airborne Dust obtained with the Thermal Precipitator : Use of Interference (J. Dodgson), 245
Microwave Ferrites and Ferrimagnetics (Dr. Benjamin Lax and Kenneth J. Button), *review* by Dr. E. W. Lee, 5
Microwave Inversion Efficiency of Orange Ruby (D. G. Jolley and S. D. McLaughlan), 898
"Microwaves, Circuit Theory and Information Theory", international conference on, 334
Migliacci, A., et *al.* : Production of a Cephalosporinase by *Pseudomonas pyocyanea* 375
Milborrow, B. V. : Penetration of Seeds by Acetone Solutes, 716
Miledi, R. : Formation of Extra Nerve-muscle Junctions in Innervated Muscle, 1191

Muntz, W. R. A. : Phototaxis and Green Rods in Urodeles, 620
Muramic Acid from two Spirochætes : *Borrelia duttoni* and *Leptospira biflexa* : Isolation and Characterization of (C. D. Ginger), 159
Murine Infection with Reovirus Type 3 and the Runting Syndrome (N. F. Stanley and P. J. Leak), 1309
Murine Lymphoma Cells capable of Proliferation *in vivo* : Quantitative Assay for the Number of (W. R. Bruce and H. van der Gaag), 79
Murphy-Sturm Lymphosarcoma after Methylcellulose-induced Regression of this Tumour in Rats : Successful Re-introduction of the (Dr. A. W. Lazar and Diane E. C. Lazar), 48
Murray, Dr. J. : A Textbook of Gynaecology and Obstetrics, *review*, 1224
Murray, Dr. Margaret : Tribute to a Centenarian (Olga Tufnell), 119
Musca Homogenates : *In vitro* Effect of Lowering Surface Energy on Esterase Activity of (H. H. Shatoury), 1192
Muscle Biopsy in Man : An Index of Cellular Potassium? (Dr. C. T. G. Flear and Irené Florence), 156
Muscle Contraction : A Molecular Theory of (Prof. R. E. Davies), 1068
Muscle Relaxant and Convulsant Drugs : Changes in the Motor Neurones after administering (Y. Y. Ahmed and J. McKenzie), 385
Muscular Contraction : Role of Adenosine Triphosphate in (I. Singh and N. V. Raju), 288
Muscular Tissues : Assessment of Functional Competence in Isolated (Dr. K. Hellmann *et al.*), 494
Muscular Type : Effect of Different Vasomotor Agents on the Vasco-elastic Behaviour of Arteries of the (H. Kulbertus), 1193
Museum of Comparative Zoology, Harvard College : Annual report 1961-62, 121
Museums Association (Dr. F. S. Wallis), 1048
Mutagens : Different 'Spectra' of Mutant Types of Extra-cellular Treatment of Phage Kappa with Differing (R. W. Kaplan *et al.*), 932
Mutations in Barley with Ultra-violet Radiation : Induction of (A. T. Natarajan and S. Nirula), 822
Mycelium of *Streptomyces pilosus* : Piloquinone : a New Phenanthrene-o-Quinone isolated from the (J. Polonsky and E. Lederer), 285
Mycobacterium tuberculosis H37Rv grown *in vivo* (*LH37Rv*) on Ehrlich Carcinoma Ascites Cells : Effect of (M. Artman and A. Bekierkunst), 1308
Mycological Congress, The third European, 122
Mycostasis and Free Monosaccharides in Soils : Relationships between (D. A. Griffiths and C. G. Dobbs), 408
Myelin Preparations derived from Human Brain : Skin Reaction in Children and Adults with Central Nervous System Disease after Intracutaneous Administration of (D. Böhme *et al.*), 84
Myers, J., and Jones, L. W. : A Common Link Between Photosynthesis and Respiration in a Blue-Green Alga, 670
Myllylä, G., *et al.* : Hæmostatic Changes Associated with Exercise, 459
Myoglobin : Electron Microscope Examination of (K. Deutsch), 180
Myoglobin in the Urine of an Adult : Fœtal (F. L. Benoit *et al.*), 387
Myometrial and Vascular Activity : Use of Ear Chamber with Uterine Muscle Transplant to differentiate (W. J. Cliff *et al.*), 399
Myosin-Actin Cross-Bridges : Calcium-Dependent Contractions with Hydrogen Bond Formation Plus ATP Dependent Extensions of Part of the (Prof. R. E. Davies), 1068
L-Myosin and Heavy Meromyosin : Effect of Ultrasonics on the Adenosine Triphosphatase Activity and Actin-binding Ability of (M. Bárány *et al.*), 694
Myxoma Virus : Electron Microscopy of (P. J. Chapple and J. C. N. Westwood), 199

Nafissi, M. M., and Abdoh, Y. : Free Amino-acid Content of Tobacco-seeds, 178
Nagar, B. R. : Examination of the Structure of Soil Humic Acids by Pyrolysis–Gas Chromatography, 1213
Nakada, M. P., and Beard, D. B. : Interplanetary Magnetic Fields as a Cause of Comet Tails, 580
Nakamura, R. M., *et al.* : Effect of Liver Regeneration following Partial Hepatectomy on the Uptake of Tritiated Thymidine in the Pituitary Gland of the Rat, 707
Nakayama, T. O. M., and Chichester, C. O. : Astringency of Persimmons (*Diospyros kaki*, L.), 73
Namurian of the Southern Central Province : Pre-Fluvial, Autogeosynclinal Sedimentation in the (B. K. Holdsworth), 133
Naphthalenes in Cigarette Smoke (R. A. W. Johnstone and P. M. Quan), 1184
Narayan, J. : Cross-Stratification and Palæogeography of the Lower Greensand of South-east England and Bas-Boulonnais, France, 1246
Nardi, Dr. V., and Mammi, Dr. M. : Mesomorphic and Crystalline States in Polyvinyl Chloride by X-ray Diffraction, 247
Nash, T., and Allison, A. C. : Electron-donor or Electron-acceptor Properties and Carcinogenic Activity of Organic Molecules, 469
Nash, T., *et al.* : Similar Effects of Various Neutral Solutes on the Survival of *Aerobacter aerogenes* and of Red Blood Cells after Freezing and Thawing, 1113
Natarajan, A. T., and Nirula, S. : Induction of Mutations in Barley with Ultra-violet Radiation, 822
National Chemical Laboratory, Teddington : Prof. J. W. Mitchell appointed director, 430
Report for 1962, 1145
National Council for Technological Awards 1963, 1237
National Economic Development Council. *Conditions Favourable to Faster Growth*, I
National Physical Laboratory, 639
Retirement of Superintendent of the Light Division, 21
National Ports Council, 432
National Reference Library of Science and Invention, 22
National Science Foundation : *Weather Modification: Fourth Annual Report*, 1241
National University of Ireland, 1044
NATO and the Department of Scientific and Industrial Research Studentships, 644
Nature and Reactions of the Reducing Species in Aqueous Solutions irradiated with γ-rays in the Presence of Oxygen (G. Scholes and M. Simic), 276
Nature of Humic Acids (A. Burges, H. M. Hurst, S. B. Walkden, F. M. Dean and M. Hirst), 696
Naylor, P. F. D., and Evans, N. T. S. : Polystyrene Membranes for Covering Oxygen Electrodes for Use in Tissue, 911
Neale, Sir John : History in the Scientific Age. Substance of an address delivered before the Assembly of Faculties, University College, London, 735
Neale, S., *et al.* : Effect of 3,4-Dehydro-DL-Proline on Growth and Protein Synthesis, 35
Nebulæ : Model Atmospheres for Central Stars of Planetary (K. B. Gebbie and M. J. Seaton), 580
Needham, Dr. J. : Human Laws and the Laws of Nature. A Lecture delivered at Hatfield College of Technology, 1961, 1123
Nelson, A., *et al.* : Genetic Effects of Strontium-90 on Immature Germ-cells in Mice, 303

Nelson, W. O., and Lakshman, A. B. : 'Rebound Effect' of Ovulation-inhibiting Steroid in Rats, 608
Nemasperm and Pituitary Inhibition (G. Fachini, G. Toffoli, A. Gaudiano, M. Marabelli, M. Polizzi and G. Mangili), 195
Nematodes : Soil and Freshwater (Dr. T. Goodey, second edition, revised and rewritten), *review* by Dr. J. W. Seinhorst, 523
Neonatal Period : Induction of Melanotic Lesions of the Iris in Rats by Urethane given during the (F. J. C. Roe et *al.*), 1201
Neoplasms : A Lactic Dhydrogenase Elevating Agent in Association with Human (C. G. Crispens, jun.), 1202
Nerve Cell : Changes of Coenzyme (TPN) Diaphorase and TPN-linked Dehydrogenase during Axonal Reaction of the (G. W. Kreutzberg), 393
Nerve-muscle Junctions in Innervated Muscle : Formation of Extra (R. Miledi), 1191
Nervous Tissue : Biochemical and Physiological Function of Thiamine in (J. R. Cooper et *al.*), 609
Neuburg, H. A. C., et *al.* : Tritium Content of Antarctic Snow, 60
Neukom, H., et *al.*: Ferulic Acid as a Component of Glycoprotein from Wheat Flour, 287
Neurohypophysial Hormones in Lungfish and Amphibians : Pharmacological Characteristics of (B. K. Follett and H. Heller), 611
Neuromuscular Block due to *d*-Tubocurarine or Calcium Deficiency : Mechanism of the Antagonism by Tetraethylammonium of (B. Collier and K. A. Exley), 702
Neurones in Normal and Exercised Rats : An Autoradiographic Investigation with Microdensitometry : Differences in the Utilization of Tritiated Leucine by Single (Dr. J. Altman), 777
Neurones in the Hippocampus : Identification of Inhibitory (P. Gloor), 699 ; (P. Andersen, J. C. Eccles and Y. Løyning), 699
Neurospora crassa : Sedimentation Behaviour of Adenylsuccinase formed by Interallelic Complementation in (C. W. H. Partridge and N. H. Giles), 305
Neutral Hydrogen in the Viro Cluster (B. J. Robinson, K. J. van Damme and J. A. Koehler), 1176
Neutron, A Fast, Source for Radiotherapy (R. J. Berry, R. Oliver and E. H. Porter), 923 ; (P. D. Lomer and D. Greene), 923 ; (J. F. Fowler), 923
Neutron Activation : Rapid Non-destructive Analysis of Chlorine by (M. Okada and Y. Kamemoto), 276
Neutron-irradiated Inorganic Solid Compounds : Ultrasonic Effect on (N. Getoff), 593
New, D. A. T., and Stein, K. F. : Cultivation of Mouse Embryos *in vitro*, 297
New Approach to Studying the Protein-binding Properties of Penicillins (P. Acred, D. M. Brown, T. L. Hardy and K. R. L. Mansford), 758
New Calculation for the Age of the Earth from Abundances of Lead Isotopes (Dr. R. G. Ostic, Prof. R. D. Russell and P. H. Reynolds), 1150
New Development in University Extramural Work. Report of the Universities Council for Adult Education 1961-1962, 335
New Developments at Glasgow's Royal College (Dr. S. C. Curran), 843
New Instrument for Atmospheric Ozone (D. I. Wardle, C. D. Walshaw and T. W. Wormell), 1177
New Materials Testing Laboratory for the Cement and Concrete Association (H. B. Milner), 546
New Proton-containing Oxides of Titanium, Zirconium and Hafnium (F. K. McTaggart), 339
New Repeat Structural Element of Mitochondrial and Certain Cytoplasmic Membranes (Prof. F. S. Sjöstrand), 1262
New York Academy of Sciences, 650
Newall, G., and Rhodes, F. H. T. : Occurrence of *Kockelella variabilis* Wallisher in the Aymestry Limestone of Shropshire, 166
Newkirk, J. F., et *al.* : Microbial Degradation of Cephalosporin *C*., 909
Newnes Concise Encyclopaedia of Nuclear Energy (Advisory Editors : D. E. Barnes et *al.*), *review* by Dr. J. Thewlis, 1026
Newton, Dr. A. : Annual Review of Microbiology, Vol. 16, *review*, 733
Newton, Prof. L. : British Seaweeds, *review*, 417
Newton, R. C., and Barnes, D. K. : Amorphous Tumours Induced in Alfalfa by Potato Leafhoppers, 95
Ngurumanite, a New Hypahyssal Alkaline Rock from Kenya (E. P. Saggerson and L. A. J. Williams), 479
Nicholas, D. J. D., et *al.* : Nitrogen Fixation by the Leaf-nodule Endophyte of *Psychotria bacteriophila*, 396
Nicholas, E. Mary : Flow Study of Polymer Melts using Instron Rheometer, 543
Nicholls, P. B., and Paleg, L. G. : Barley Endosperm Bioassay for Gibberellins, 823
Nicholls, R. W. : Primary and Subsidiary Condon Loci of Molecular Spectra, 794
Nickel : Application of Atomic Absorption Spectroscopy to the Determination of Cobalt in Steel, Alloy Steel and (G. L. McPherson et *al.*), 371
Nickel Alloy Films : Epitaxial Oxide Growth on Thin Single-crystal Gold- (I. H. Khan and M. F. Francombe), 800
Nickel Substrates for the Development of Uniaxial Anisotropy in Electro-deposited Thin Films : Chemically Reduced (R. D. Fisher and H. E. Haber), 163
Nicolet, Prof. M. : Awarded the 1963 Guggenheim International Astronautics Award, 331
Nicotiana debneyi and *N. goodspeedii* : A Strain of *Peronospora tabacina* Pathogenic to Tobacco Lines with Resistance derived from (A. V. Hill), 396
N. goodspeedii : A Strain of *Peronospora tabacina* Pathogenic Tobacco Lines with Resistance derived from *Nicotiana debneyi* and (A. V. Hill), 396
Nicotinamide-adenine Dinucleotides, Adenosine Diphosphate and Adenosine Triphosphate Content of Tissues infected by Tobacco Mosaic Virus (D. W. Sunderland and M. J. Merrett), 1116
Nicotinamide Adenine Dinucleotide Phosphate by Illuminated Chloroplasts : Pathway of Reduction of Metmyoglobin and (Dr. H. E. Davenport), 151
Nicotinamide Adenine Nucleotides in Ovine Liver (D. S. P. Patterson), 402
Niecikowski, H., and Nishmi, M. : Interaction of Vaccinia Virus and Cells in Primary and Continuous Culture, 1117
Nielsen, C. O. : Laminarinases in Soil and Litter Invertebrates, 1001
Night Sky in August, 232 ; September, 434 ; October, 1044
Nightglow H_α-emission to the Ecliptic and the Radial Velocities of this Line : Concentration of (Prof. P. V. Sheglov), 990
Nilawar, B. B., et *al.* : Equilibria in Water-Alcohol Mixtures, 692
Niobium : Twinning at 77°K of 'Flash-annealed' (Mlle. A. Fourdeux and A. Wronski), 1284
Nirula, S., and Natarajan, A. T. : Induction of Mutations in Barley with Ultra-violet Radiation, 822
Nishmi, M., and Niecikowski, H. : Interaction of Vaccinia Virus and Cells in Primary and Continuous Culture, 1117
Niskanen, E. E., and Arley, N. : A Stochastic Model of Carcinogenesis compared with Mouse Skin Tumour Enhancement after Gastric Instillation of 9,10-Dimethyl-1,2-Benzanthracene with Subsequent Local Continuous Exposure to 'Tween 40', 83
Nisonoff, Dr. A., et *al.*: Distribution of Allotypic Specificities among Rabbit γ-Globulin Molecules Genetically Defined at Two Loci, 52
Nitowsky, H. M., et *al.* : Skin Biopsy for Cell Culture, 296
Nitrogen Fixation by the Leaf-nodule Endophyte of Psychotria bacteriophila (W. S. Silver, Y. M. Centifanto and D. J. D. Nicholas), 396
Nitrogen, Fixation of Atmospheric, by Root Nodules of *Comptonia peregrina* (H. Ziegler and R. Hüser), 508
Nitrogen Gas in the Reaction Product of Nitrous Acid and Lignin : Occurrence of a Previously Unobserved (F. J. Stevenson and R. J. Swaby), 97
Nitrogenous Components of Phospholipids extracted from *Penicillium chrysogenum* (Prof. W. L. Gaby and Eleanor H. McCurley), 1187
N-nitroso-*N*-alkylurethanes : Induction of Tumours of the Stomach in Rats and Mice by (R. Schoental), 190
Nitrous Acid and Lignin : Occurrence of a Previously Unobserved Nitrogen Gas in the Reaction Product of (F. J. Stevenson and R. J. Swaby), 97
Nixon, D. A., et *al.* : Perfusion of the Viable Sheep Fœtus, 183
Nixon, W. L. B., et *al.* : A Mathematical Model of a Perceptual Maze Test, 676
Noble, Dr. D. : Biophysics of the Striated Muscle, second edition, *review*, 1224
Noble, D., and Hall, A. E. : Transient Responses of Purkinje Fibres to Non-uniform Currents, 1294
Noble, R. E., et *al.* : Incorporation of Propionic Acid into a Branched-chain Fatty Acid of the Preen Gland of the Goose, 600
Noci, Dr. G. : Ionospheric Effects Due to the Earth's Orbital Position, 968
Noci, G. C., et *al.* : Solar Flux Fluctuations at 225 Mc/s and Noise-level of Atmospherics at 27 Kc/s, 363
Noctilucent Clouds : Particle Sampling from (C. L. Hemenway et *al.*), 269
Node of Ranvier : Ultrastructure of the (D. N. Landon and P. L. Williams), 573
Nodes, J. T., and Reid, E. : Acid Ribonuclease in Liver Cell Sap, 176
Noise, Problems of, 231
Noll, Prof. H., et *al.* : Structure and Function of *E. Coli* Ergosomes, 865
Nomad Fulani, 961
Non-destructive Radioanalytical Method for the Determination of Gallium in Substituted Yttrium Iron Garnets (J. P. Cali, J. R. Weiner and J. J. O'Connor), 1081
Non-destructive Testing : Fourth International Conference on, 232
Non-enzymatic Browning : Browning of Phenols and its Inhibition by Sulphur Dioxide (H. S. Burton, Dr. D. J. McWeeny and P. N. Pandhi), 659
Non-enzymatic Oxidative Degradation of Cellulose occurring in Preserved Cabbage Tissue (J. C. Dakin), 383
Non-metamorphosed Sediments in Israel : High-temperature Minerals in (Y. K. Bentor et *al.*), 478
Nordisk Institut for Teoretisk Atomfysik : Annual Report, 1960-61, 960
Annual Report, 1961-62, 960
Norepinephrine in the Heart : Origin of (I. J. Kopin and E. K. Gordon), 1289
Norman, Dr. D., and Schultz, Dr. R. D. : Effects of Plant Growth Regulators (Auxins and Auxin Esters) on the Survival of Free Cells of the Ehrlich Ascites Carcinoma, 260
Norman, J. R. : A History of Fishes (second edition revised by P. H. Greenwood), *review* by Q. Bone, 522
Norsk Polarinstitutt, Skrifter Nr. 126 : *Glaciological Bibliography of Norway*, 966
Skrifter Nr. 114 : *Glaciers and Snowfields in Norway*, 966
North-East of Scotland : A Survey prepared for the Aberdeen Meeting of the British Association for the Advancement of Science, 1963, *review*, 891
North, F. J. : Mining for Metals in Wales, 1125
Norton, D. A., et *al.* : Molecular Geometry of 7a-Bromocholesteryl Chloride, 1180
Norton, Dr. D. A., and Ohrt, Jean M. : Molecular Geometry of Lanosteryl Iodoacetate, 864
Norwegian Glaciers (G. de Q. Robin), 966
Norwegian Minerals and Rocks of Possible Caledonian Origin (I. Hernes), 686
Nossal, G. J. V., et *al.* : Behaviour of Active Bacterial Antigens during the Induction of the Immune Response, 1257, 1259
Nour-Eldin, F. : Antihæmophilic Globulin in Frozen Plasma, 187
Novikoff Reaction for Thiamine Pyrophosphatase : Capillary Plexuses in Gastropods Stained by the (O. L. Thomas), 89
Nuclear Energy : Newnes Concise Encyclopaedia of (Advisory Editors : D. E. Barnes, et *al.*), *review* by Dr. J. Thewlis, 1026
Nuclear Energy Research, United Kingdom Funds, 22
Nuclear Explosion : Magnetotelluric and Very Low Frequency Signatures from Small High-Altitude (R. A. Santirocco and D. G. Parker), 1273
Nuclear Factors involved in the Radiation-induced Depression of DNA Synthesis of Deoxyribonucleic Acid (S. M. Lehnert and S. Okada), 1108
Nuclear Fusion, 645
Nuclear Graphite : OEEC Dragon Project Symposium, Bournemouth, 1959, *review* by F. Roberts, 415
Nuclear Magnetic Resonance in Molecules of Moderate and High Molecular Weight (Dr. D. W. Jones), 130
Nuclear Power Politics in Britain, 1121
Nuclear Reactors : Output Capacity of, 231
Nuclear Safety Advisory Committee : Members appointed, 962
Nuclear Science : Annual Review of, Vol. 12 (edited by Emilio Segre), *review* by Dr. T. E. Cranshaw, 418
Nuclear Science and Engineering Corporation : Directors appointed, 331
Nuclear Sciences, Literature in, 645
Nuclear Test Ban, 1219
Nuclei : Size and Growth of Cavitation Bubble (M. M. Hasan and K. S. Iyengar), 995
Nucleic Acids : A Possible Mechanism of Synthesis of (J. A. V. Butler), 68
Radiosensitive Molecular Weight of Single-stranded Virus (Dr. W. Ginoza), 453
Use of Alkyltrimethylammonium Bromides for the Isolation of Ribo- and Deoxyribo- (A. S. Jones), 280
Nucleic Acids and Protein Contents of the Thyroid : Effect of Thyrotropin on (R. Ekholm and V. Pantić), 1203
Nucleic Acids of Yeast by Ionizing Radiation : *In vivo* Investigation of the Removal of Trace Elements from (H. Altmann et *al.*), 823
Nucleoprotein Fractions of Mouse Spleen Cells during Antibody Formation : Persistence of Antigen in (H. Friedman), 502
Nucleotide Sequence Investigations in Microsomal Ribonucleic Acids of Normal and Rous Sarcoma Virus-infected Tissues (N. Delihas and E. Evans), 488
Nucleotides : Reaction of Hydrogen Chloride Gas on RNA and its Component (M. E. Bramwell), 811
Nucleotides on the Biosynthesis of Porphyrins by *Rhodopseudomonas spheriodes* : Inhibitory Action of Adenine, Adenine Nucleosides and (A. Gajdos and M. Gajdos-Török), 1093
Nuclides : Use of Complex Ions in the Efficiency Tracing Methods for the Standardization of Pure Beta-emitting (T. T. Gorsuch et *al.*), 368
Nuclides in Ground-level Air and Human Lungs during Spring 1962 : Plutonium-239 and other (Dr. R. V. Osborne), 143
Núñez, J. A. : Central Nervous Control of the Mechanical Properties of the Cuticle in *Rhodnius prolixus*, 621
Nutrient Requirement for Optimum Water Absorption by Intact Root Systems (D. H. Drew), 93
Nutrition of Pigs and Poultry : Proceedings of the University of Nottingham Eighth Easter School in Agricultural Sciences, 1961 (edited by Dr. J. T. Morgan and Dr. D. Lewis), *review* by Dr. A. Eden, 521

Nutrition of the Chicken : Effect of Raw Wheat Germ on (J. A. Parrish and R. J. Bolt), 398
Nutritional Stress before Mating : Infertility in Mice caused by (T. J. McClure), 504
Nyholm, Prof. R. S. : Appointed to the headship of the Department of Chemistry, 748
Nyholm, Prof. R. S., et *al.* : Eight Co-ordination in the Early Transition Series, 559

OAKLEY, Dr. : *Man and the Tool Maker*, fifth edition (British Museum (Natural History)), 1042
Oakley, Prof. C. L. : Appointed a member of the Agricultural Research Council, 748
Oat Leaves : Kinin-induced Directed Transport and Senescence in Detached (Dr. B. E. S. Gunning and W. K. Barkley), 262
Oats : Physiological Specialization in *Erysiphe graminis* DC. in (J. D. Hayes and W. S. Catling), 1111
Occultation Theory of Jovian Radio Outbursts (A. G. Smith, N. F. Six, T. D. Carr and G. W. Brown), 167
Occurrence in Egg Yolk of Plasmalogenic Triglycerides (M. Prošťenik and M. Popović), 1285
Occurrence of Hæmoglobin H in Leukæmia (G. H. Beaven, B. L. Stevens, N. Dance and J. C. White), 1297
Occurrence of Karroo System Sediments in Ethiopia (P. A. Mohr), 1086
Occurrence of *Kockelella variabilis* Walliser in the Aymestry Limestone of Shropshire (F. H. T. Rhodes and G. Newall), 166
Occurrence of a Previously Unobserved Nitrogen Gas in the Reaction Product of Nitrous Acid and Lignin (F. J. Stevenson and R. J. Swaby), 97
Occurrence of Pseudo-Barbiturates in Post-mortem Material (J. V. Jackson and B. S. Finkle), 1061
Occurrence of Two Different Enzymes in the Silkworm, *Bombyx mori*, to reduce Folate and Sepiapterin (M. Matsubara, M. Tsusue and M. Akino), 908
Oceancurrents : On the Influence of the Earth's Rotation on, reprint of the 1905 paper by V. W. Ekman, 645
Oceanic Areas : Correlation of Widely Spaced Magnetic Profiles in (Dr. D. H. Griffiths and R. P. Riddihough), 251
Oceanography at the Smithsonian Institution (Dr. I. E. Wallen), 1227
O'Connor, Dr. J. : Appointed research associate at the Institute for Scientific Information, Philadelphia, 122
O'Connor, J. J., et *al.* : Non-destructive Radioanalytical Method for the Determination of Gallium in Substituted Yttrium Iron Garnets, 1081
Octopus : 5-Hydroxytryptamine in the Spermatophoric Sac of the (Dr. T. Mann), 1066
Odhiambo, T. R. : The East African Academy : First Symposium and Inaugural Annual General Meeting, 439
Œstrogen on Fertility in Ewes : Effects of (F. H. W. Morley, A. Axelsen and D. Bennett), 403
Œstrogenized Immature Pullet : Isolation of Phosvitin from the Plasma of the (P. J. Heald and P. M. McLachlan), 487
Œstrous Cycle : Flow of Uterine Blood and the (I. J. Kopin and R. J. Wurtman), 386
Official, Standardized and Recommended Methods of Analysis (compiled and edited by S. C. Jolly), *review* by Dr. T. S. West, 210
Oftebro, R., et *al.* : A Water-soluble Polypeptide Prepared from Zymosan, 465
Oftedal, P. : Induction of Mutations and Killing of Cells in Irradiated Spermatogonia of *Drosophila*, 1301
Ohrt, J. M., et *al.* : Molecular Geometry of 7a-Bromocholesteryl Chloride, 1180
Ohrt, J. M., and Norton, Dr. D. A. : Molecular Geometry of Lanosteryl Iodoacetate, 864
Oil in Navigable Waters, 537
Oil Spot Disease in Tea (D. Mulder, N. Shanmuganathan and P. V. Arulpragasam), 92
Okada, M., and Kamemoto, Y. : Rapid Non-destructive Analysis of Chlorine by Neutron Activation, 276
Okada, S., and Lehnert, S. M. : Nuclear Factors involved in the Radiation-induced Depression of DNA Synthesis of Deoxyribonucleic Acid, 1108
Oldfield-Box, H., and Kay, H. : Use of 3-Dimensional Shapes for Investigation of Learning Sets in the Rat, 1018
Oldroyd, H. : Annual Review of Entomology, Vol. 8, *review*, 108
O'Leary, W. M., and Weld, J. T. : Events associated with Development of Lipid Plaques on Plasma Agar, 510
Olfaction : Stereochemical Theory of (B. Fullman), 912 ; (J. E. Amoore), 912
Olfactory Relationships of the Diencephalon (T. P. S. Powell, W. M. Cowan and G. Raisman), 710
Olfactory Tract : Centrifugal Fibres in the Lateral (T. P. S. Powell and W. M. Cowan), 1296
Oligochæta New to Britain : A Genus of Brackish-water (R. O. Brinkhurst), 1206
Oliver, R., et *al.* : Fast-neutron Source for Radiotherapy, 923
Olivereau, M., et *al.* : Secretion of Thyrotrophic Hormone by Pituitary Transplants in a Teleost Fish, 618
Ollis, Prof. W. D. : Appointed to the chair of Organic Chemistry, 959
Ondráčková, J., et *al.* : Changes occurring in the Excretion of Radiorubidium by Saliva in Rats after Whole-body Irradiation, 1008
Onions, W. J., and Marcet, J. : Incidence, Size and Shape of Meta-cortex Fibres in Wool, 1306
Ontario Research Foundation. Annual Report 1962, 1145
Oocytes of *Aplysia depilans* L. : Presence of Ribonucleic Acid in the Initial Yolk Globules of (A. Bolognari and A. Donato), 697
Opaline Silica Deposition in *Molinia caerulea* L. : Influence of Mechanical Damage on (D. W. Parry and F. Smithson), 925
Operator Techniques in Atomic Spectroscopy (Prof. Brian R. Judd), *review* by Prof. K. W. H. Stevens, 1222
d'Ophthalmologie, II : Problèmes Actuels (Dirigé par E. B. Streiff), *review* by R. A. Weale, 1221
Ophthalmology : Advances in, Vol. 13 (edited by E. B. Streiff), *review* by R. A. Weale, 1221
Opie, P. : The Tentacles of Tradition, 886
Oppenheimer, H., et *al.* : Effect of Ultrasonics on the Adenosine Triphosphatase Activity and Actin-binding Ability of L-Myosin and Heavy Meromyosin, 694
Optical Radar : Detection of Scattering Layers in the Upper Atmosphere (60-140 km) by (G. Fiocco and L. D. Smullin), 1275
Optical Rotatory Power of the Polypeptide α-Helix : A Reconsideration of the Moffitt Theory (Dr. S. F. Mason), 139
"Optics of Solid Thin Layers", colloquium on, 334
Orange Ruby : Microwave Inversion Efficiency of (D. G. Jolley and S. D. McLaughlan), 898
Organ Culture : Effect of Puromycin on Cholinesterase Activity of Embryonic Chick Intestine in (A. Burkhalter), 598
Organ Culture System for the Examination of Tumour Invasion (G. C. Easty and D. M. Easty), 1104
Organ Pipes, 433
Organic Chemistry : Prof. W. D. Ollis appointed to the chair of, 959
Organic Compounds from Simple Precursors : Synthesis of Complex (Prof. C. U. Lowe et *al.*), 219
Organic Molecules : Electron-donor or Electron-acceptor Properties and Carcinogenic Activity of (B. Pullman and A. Pullman), 467 ; (A. C. Allison and T. Nash), 469
Organization for Economic Co-operation and Development *Radiation Protection Norms*, 960
Organization for European Co-operation and Development, 960
Organizing Scientific and Industrial Research in Britain, 207
Organomercury Compounds on Dressed Grain after Washing : Retention of (N. A. Smart), 1206
Orionis : Radio Emission from Flare Star V371 (O. B. Slee et *al.*), 991
Orlans, Harold : The Effects of Federal Programs on Higher Education, *review* by Sir Harry Melville, 837
Orotic Acid on the Synthesis of Citrovorum Factor and of Methionine in Liver of the Chick : Effect of (G. Moruzzi, M. Marchetti and R. Viviani), 695
Orton, B. R. : Liquid Metals, 1239
Osborne, R. V. : Lead-210 and Polonium-210 in Human Tissues, 295
Plutonium-239 and other Nuclides in Ground-level Air and Human Lungs during Spring 1962, 143
Osoba, Dr. D., and Miller, Dr. J. F. A. P. : Evidence for a Humoral Thymus Factor Responsible for the Maturation of Immunological Faculty, 653
Osteoclasts : Multinuclearity of (A. J. Schmidt), 1113
Ostic, Dr. R. G., et *al.* : New Calculation for the Age of the Earth from Abundances of Lead Isotopes, 1150
Oswald, Ian : Sleeping and Waking : Physiology and Psychology, *review* by D. E. Broadbent, 416
Ouabain Inhibition of Cation Activated Adenosine Triphosphatase : Evidence of the Mechanism of (J. S. Charnock and R. L. Post), 910
Outline of Human Genetics (Prof. L. S. Penrose), *review* by Dr. C. A. Clarke, 730
Outteridge, R. A. : World List of Forensic Science Laboratories, *review*, 317
Overnight Incubation Technique for obtaining Transformable *Bacillus subtilis* Cells of Reproducible Competency (D. Bobb), 828
Overseas Surveys : Directorate of, 1230
Ovine Egg : Capacitation of Ram Spermatozoa and Penetration of the (P. E. Mattner), 772
Ovine Liver : Nicotinamide Adenine Nucleotides in (D. S. P. Patterson), 402
Ovulation-inhibiting Steroid in Rats : 'Rebound Effect' of (A. B. Lakshman and W. O. Nelson), 608
Owen, D. F. : Polymorphism in Living and Pleistocene Populations of the African Land Snail, *Limicolaria* martensiana, 713
Ox : A Simple Method for the Display of Chromosomes from Cultures of White Blood Cells with Special Reference to the (J. D. Biggers and R. A. McFeely), 718
Oxidation of Reduced Glutathione by Acetylphenylhydrazine, Hæmoglobin and Erythrocytes (Doris Balinsky and R. E. Bernstein), 187
Oxidative Phosphorylation at the Pyridine Nucleotide/Flavoprotein Level : Mechanisms for (Dr. J. A. Barltrop et *al.*), 759
Oxides of Titanium, Zirconium and Hafnium : New Proton-containing (F. K. McTaggart), 339
Oxidized Proteins in the Examination of Immunochemical Specificity in Delayed Hypersensitivity to Hapten-Protein Conjugates : Use of (S. Leskowitz), 85
Oxygen : Nature and Reactions of the Reducing Species in Aqueous Solutions irradiated with γ-rays in the Presence of (G. Scholes and M. Simic), 276
Oxygen and Iron on the Production of Fluorescin and Cytochrome *c* by *Pseudomonas fluorescens* : An Inverse Relationship of the Effects of (H. Lenhoff), 601
Oxygen at a Carbon Electrode Emerging from an Electrolyte : Reduction of (S. R. Faris), 754
Oxygen, Effects of, on the Rabbit During Surface Cooling Down to Cardiac Arrest (Dr. B. Broom), 1155
Oxygen Electrodes for Use in Tissue : Polystyrene Membranes for Covering (P. F. D. Naylor and N. T. S. Evans), 911
Oxygen in *Euglena gracilis* : Linear Relationship between Temperature and Uptake of (D. E. Buetow), 196
Oxygen in the Gas Vacuole of the Rhizopod Protozoan, *Arcella* (Anna Cicak, J. J. A. McLaughlin and Prof. J. B. Wittenberg), 983
Oxygen through Hæmerythrin Solutions : Facilitated Diffusion of (J. B. Wittenberg), 816
Oxygenases (edited by Osamu Hayaishi), *review* by Prof. S. Dagley, 109
Oxytocin and Arginine-Vasopressin : Carbamylation of (G. W. Bisset et *al.*), 69
Ozone in Discharge-flow Experiments : Some Reactions of (Dr. M. A. A. Clyne et *al.*), 1057

P, SUBSTANCE, content and effect on Capillary Permeability of Extract of Various Parts of Human Brain (F. Lembeck and K. Starke), 1295
Paal, G., et *al.* : Skin Reaction in Children and Adults with Central Nervous System Disease after Intracutaneous Administration of Myelin Preparations derived from Human Brain, 84
Pace, G., and Pierpaoli, W. : Photodynamic Effect of Diidroquinidine on Isolates Hearts of Mammals, 915
Pacemaker Hierarchies Controlling the Behaviour of Hydras (Dr. L. M. Passano and Mrs. C. B. McCullough), 1174
Pacer, R. A., et *al.* : Pertechnic Acid : an Aperiodic Variation in Acid Strength, 66
Page, D. H., and Tydeman, P. A. : Transverse Swelling and Shrinkage of Softwood Tracheids, 471

Pearson, A. M., *et al.* : Cæsium-137 Content of Lambs, 294
Peck, D. S., and Schmid, E. R. : Effects of Radiation on Transistors in the First *Telstar* Satellite, 741
Penetration of Pyrethrin I Labelled with Carbon-14 into Susceptible and Pyrethroid Resistant Houseflies (B. C. Fine, P. J. Godin and E. M. Thain), 927
Penetration of Seeds by Acetone Solutes (B. V. Milborrow), 716
Peng, C. Y., and Markakis, P. : Effect of Phenolase on Anthocyanins, 597
Penicillin with Unusual Properties : Quinacillin : a New (Dr. H. C. Richards et *al.*), 354
Penicillium chrysogenum : Nitrogenous Components of Phospholipids extracted from (Prof. W. L. Gaby and Eleanor H. McCurley), 1187
Penicillium rubrum Stoll : Pigment Formation by (S. N. Sen), 71
Penicillins : A New Approach to Studying the Protein-binding Properties of (P. Acred et *al.*), 758
Penman, Dr. H. L. : Vegetation and Hydrology (Technical Communication No. 53 of the Commonwealth Bureau of Soils), *review* by Prof. W. H. Pearsall, 316
Pennelli, N., *et al.* : Mast Cell Reaction and 5-Hydroxytryptamine Content in the Skin of Syrian Golden Hamsters painted with 9:10-Dimethyl-1:2-benzanthracene, 293
Penology : Problems of (Prof. W. J. H. Sprott), 890
Penrose, Prof. L. S. : Outline of Human Genetics, *review* by Dr. C. A. Clarke, 730
Pentobarbitone on Exploratory Behaviour in Rats : Effects of Amphetamine and (Dr. R. Stretch), 787
People of the Forest (Hans Lidman), *review* by Frances Pitt, 314
Peppers, N. A., *et al.* : Retinal Photocoagulation by Lasers, 146
Pepsin and its Dependence on a Possible 'Hydrophobic Binding Site' : Specificity of (J. Tang), 1094
Pepsinogen : Reduction and Reoxidation of the Disulphide Bonds of (V. Frattali et *al.*), 1186
Peptide Linkage by Prostatic Ribosomes : Influence of Testosterone and Polyuridulic Acid on the Incorporation of Phenylalanine into (D. A. Silverman et *al.*), 808
Pepys, Dr. J. : Allergology : Proceedings of the IVth International Congress of Allergology, October 1961, *review*, 629
Pereira, H. G., *et al.* : Analysis of Adenovirus Particles and Soluble Antigens produced in the Presence of 5-Bromodeoxyuridine, 1210
Perez, J. C., *et al.* : Cæsium–Choline Interaction on Muscle Membrane, 815
Perfusion of the Viable Sheep Fœtus (D. A. Nixon, H. G. Britton and D. P. Alexander), 183
Periclinal Chimæra in Tea (I. St. E. Samarawira), 824
Perineural Epithelium : Nature and Significance (Dr. T. R. Shanthaveerappa and Prof. G. H. Bourne), 577
Periodic (Liesegang) Precipitation of Chemicals (A. J. Crowle, D. C. Lueker and H. S. Gaskill, jun.), 623
Perkin Centenary Trust Awards, 1140
Perkins, P. J., *et al.* : An Indication of Underwater Sound Production by Squid, 250
Perlmann, Dr. P., and Klein, Prof. G. : *In vitro* Cytotoxic effect of Isoantibody Measured as Isotope Release from Labelled Target Cell DNA, 451
Permo-Carboniferous Coal Measures of the Transvaal : A New Cycadeoid Plant from the (S. F. Le Roux), 1010
Peronospora tabacina Pathogenic to Tobacco Lines with Resistance derived from *Nicotiana debneyi* and *N. goodspeedii* : A Strain of (A. V. Hill), 396
Peroxidase in the Metabolism of Leucocytes : Role of Catalase and (M. Rechcigl, jun., and W. H. Evans), 1001
Peroxidase Isozymes in Root Nodules of Various Leguminous Plants (Dr. E. Moustafa), 1189
Persimmons (*Diospyros kaki*, L.) : Astringency of (T. O. M. Nakayama and C. O. Chichester), 73
Persistence of Antigen in Nucleoprotein Fractions of Mouse Spleen Cells during Antibody Formation (H. Friedman), 502
Personal Values in Education (Sir Charles Morris), 889
Personality : Biological Basis of (Prof. H. J. Eysenck), Substance of the Thomas Young Lecture delivered at St. George's Hospital Medical School, June 1963, 1031
Pertechnic Acid : an Aperiodic Variation in Acid Strength (C. L. Rulfs, R. F. Hirsch and R. A. Pacer), 66
Perutz, Dr. M. F., and Mazzarella, L. : A Preliminary X-ray Analysis of Hæmoglobin H, 639
Perutz, Dr. M. F., and Muirhead, H. : Structure of Hæmoglobin, 633
Peters, A., and De Bock, C. A. : Effect of Thalidomide on the Development of the Chick Embryo, 1204
Peters, R. H., *et al.* : Equilibria in Water–Alcohol Mixtures, 692
Petree, M. C., and Warfield, R. W. : Polymerization of a Thermosetting Polymer in an Electric Field, 67
Petrofabric Analysis of Quartz using the Point-counter (A. G. Milnes), 445
Petroleum : Distribution of *n*-Paraffins in Crude Oils and their Implications to Origin of (R. L. Martin et *al.*), 110
Duplex Origin of (Sir Robert Robinson), 113
Petroleum Consumption in the United Kingdom, 1962, 433
Petroleum in 1975 (H. B. Milner), 133
Petroleum Industry : Speeding the Pace of Technological Development in the (H. B. Milner), 436
Petrology and Hydrocarbon Content : A Beacon Sandstone : (R. B. Elliott and W. D. Evans), 686
Petropoulos, Prof. G. M. : *Obituary* by Dr. T. E. Allibone, 852
Pfeiffer, C. J., *et al.* : Reduction by Chlorpromazine of Pylorus-ligation Ulcers in the Rat, 1296
Pfeiffer, E. W., *et al.* : Influence of Diet on Urine Concentration in *Aplodontia rufa* and the Rabbit, 181
Pfeiffer, R. A., *et al.* : Preparation of Bovine Chromosomes, 719
Phage Kappa with Differing Mutagens : Different 'Spectra' of Mutant Types of Extra-cellular Treatment of (R. W. Kaplan *et al.*), 932
Phagocytosis : Influence of Isolated Components of the Uterine Secretion of (Jean Killingbeck et *al.*), 255
Phagocytosis by Human Blood Leucocytes : Identification of a Somatic Antigen of *Staphylococcus aureus* critical for (S. Mudd et *al.*), 1200
Pharmacological Characteristics of Neurohypophysial Hormones in Lungfish and Amphibians (B. K. Follett and H. Heller), 611
Pharmacological, The second International Meeting, 24
Pharmacology : Annual Review of, Vol. 2 (edited by Windsor C. Cutting), *review* by Dr. M. J. Rand, 210
Dr. K. Lederis appointed lecturer in, 434
Phenanthrene-o-Quinone isolated from the Mycelium of *Streptomyces pilosus* : Piloquinone : a New (J. Polonsky and E. Lederer), 285
Phenol Red : Inability of the Kidney of the Hagfish to secrete (R. Fänge and J. Krog), 713
Phenolase on Anthocyanins : Effect of (C. Y. Peng and P. Markakis), 597
Phenolic Compounds : A Postulated Biosynthesis of Some 'Anomalous' Natural (T. Money), 592
Phenols and its Inhibition by Sulphur Dioxide : Non-enzymatic Browning : Browning of (H. S. Burton et *al.*), 659
Phenoxyacetic Acid by Stem Tissue of *Avena sativa* : Hydroxylation of (E. W. Thomas et *al.*), 73
Phenoxy Radicals with Methyl Radicals in the Gaseous Phase : Reaction of (M. F. R. Mulcahy and D. J. Williams), 761
Phenylalanine into Peptide Linkage by Prostatic Ribosomes : Influence of Testosterone and Polyuridylic Acid on the Incorporation of (D. A. Silverman et *al.*), 808
O-Phenylphenol to Reduce the Rotting of Stored Fruit : Use of Paper Impregnated with Esters of (Dr. R. G. Tomkins), 669
Philbrook, G. E., *et al.* : Light Emission during the Neutralization Reaction in Presence of a Chemiluminescent Radical Indicator, 595
Phillips, Dr. C. S. G. : Gas Chromatography, *review*, 210
Phillips, C. S. G., and Scott, C. G. : Trace Analysis by Combined Chromatographic Technique, 66
Philosophy : Introduction to Comparative (P. T. Raju), *review* by F. I. G. Rawlins, 519
Pholidoptera : Sound Signals and Alternation Behaviour in (M. D. R. Jones), 928
Phonon Concept at High Temperatures (D. Probert), 165
Phosphagens Function as Phosphoryl-Transfer Reagents ? Who do (Dr. V. M. Clark and S. G. Warren), 657
Phosphatase in Cattle Serum : Genetic Variation of (Bo Gahne), 305

Phosphate : Inhibition of 6-Mercaptopurine-resistant Cancer Cells in Culture by *Bis*(Thioinosine)-5',5'''- (J. A. Montgomery et *al.*), 769
Phosphines : Binding of the Thiocyanate Ion in Complexes with Palladium (II)-containing Tertiary (E. Frasson et *al.*), 803
Phospholipid Complexes : Reversal of Solubility Characteristics of 'Luxol' Dye- (T. N. Salthouse), 821
Phospholipids extracted from *Penicillium chrysogenum* : Nitrogeneous Components of (Prof. W. L. Gaby and Eleanor H. McCurley), 1187
Phosphoprotein as an Intermediate in Cerebral Microsomal Adenosine-triphosphatase (S. P. R. Rose), 375
Phosphors : Stimulated Singlet–Triplet Transitions in Organic (F. Wilkinson and E. B. Smith), 691
Phosphoryl-Transfer Reagents ? Who do Phosphagens Function as (Dr. V. M. Clark and S. G. Warren), 657
Phosphorylation : A Hypothesis linking the Succinic Dehydrogenase System to an Intermediate of Oxidative (O. Gawron), 377
Phosvitin from the Plasma of the Œstrogenized Immature Pullet : Isolation of (P. J. Heald and P. M. McLachlan), 487
Photobiology Group : Annual General Meeting, 748
Photodynamic Effect of Diidroquinidine on Isolated Hearts of Mammals (G. Pace and W. Pierpaoli), 915
Photoelectric Spectrometry Group meeting on "Reflectance Spectroscopy", 1238
Photographic Method for the Detection of Rare Bacterial Mutants in the Replica Plating Technique (J. H. van de Pol, C. M. A. Vendrig and G. A. von Arkel), 198
Photometric Observations of the Aurora of October 28, 1961 (Dr. S. M. Silverman, *erratum* 198, 678), 24
Photosynthesis and Respiration in a Blue-Green Alga : A Common Link between (L. W. Jones and J. Myers), 670
Photosynthetic Reactions by the Use of Monochromatic Light : Analysis of (Dr. K. Tagawa et *al.*), 1247
Phototaxis and Green Rods in Urodeles (W. R. A. Muntz), 620
Physical Approach to Chemical Structure (Prof. J. M. Robertson), 883
Physical Transitions of the Alkali Metal Nitrates as Revealed by Differential Thermal Analysis (E. S. Freeman and D. A. Anderson), 63
Physics : Dr. R. R. Birss appointed lecturer in, 1044
Prof. B. H. Bransden appointed to the chair of, 745
Prof. S. F. Edwards appointed to the chair of, 643
Dr. R. M. Hobson appointed lecturer in, 434
Dr. S. E. Hunt appointed head of the Department of, 535
A. Keller appointed lecturer in, 434
Dr. D. H. Martin appointed reader in, 1044
Dr. J. M. Ziman appointed to the chair of, 434, 536
Physics in Africa (Dr. J. M. A. Lenihan), 749
"Physics of Electronic and Atomic Collisions", Third International Conference on, 231
"Physics of Optical Glass", conference on, 748
Physics of the Upper Atmosphere (edited by J. A. Ratcliffe), *review* by Dr. R. L. Smith-Rose, 728
Physics Today : Understanding (W. H. Watson), *review* by the late T. M. Yarwood, 841
Physiological Specialization in *Erysiphe graminis* DC. in Oats (J. D. Hayes and W. S. Catling), 1111
Physiology of Earthworms (M. S. Laverack), *review* by Dr. R. Phillips Dales, 314
Physiology of the Eye (Hugh Davson), second edition, *review* by R. A. Weale, 1221
Phytoene and Lycopersene : Comparison of the Reaction of *N*-bromosuccinimide with (Prof. T. W. Goodwin and D. M. Thomas), 491
Phytopathogenic Pseudomonads : Rapid Detection of the Pathogenicity of (Z. Klement), 299
Piccard, Prof. J. F. : *Obituary* by Prof. C. C. Chang, 229
Picornavirus Reproduction : Synergistic Effect of 2-(α-Hydroxybenzyl)-benzimidazole and Guanidine on (H. J. Eggers and I. Tamm), 513
Pierpaoli, W., and Pace, G. : Photodynamic Effect of Diidroquinidine on Isolates Hearts of Mammals, 915
Pig : Environmental Temperature preferred by the Young (L. E. Mount), 1212
Pigment Formation by *Penicillium rubrum* Stoll : (S. A. Sen), 71
Pigment produced from Vitamin B_{12} by *Aerobacter aerogenes* : Biological Activity of a Brownish-Yellow (K. Helgeland et *al.*), 604
Pigott, S. W., et *al.* : Hydrostatic Extrusion, 485
Pigs and Poultry : Nutrition of, Proceedings of the University of Nottingham Eighth Easter School in Agricultural Sciences, 1961 (edited by Dr. J. T. Morgan and Dr. D. Lewis), *review* by Dr. A. Eden, 521
Pike, E. R. : A Fundamental Extension of Einstein's Diffusion–Mobility Relationship, 994
Pike, M. C. : The Foundations of Statistical Inference : A Discussion, *review*, 630
Pilgeram, L. O. : Adenosine Triphosphate : an Inhibitor of Generation of Thromboplastin, 708
Pilgrim, C., et *al.* : Diurnal Fluctuations in the Numbers of DNA Synthesizing Nuclei in Various Mouse Tissues, 863
Piloquinone : a New Phenanthrene-o-Quinone isolated from the Mycelium of *Streptomyces pilosus* (J. Polonsky and E. Lederer), 285
Pimental, E., and Posner, I. : Further Separation of Iodine, Monoiodotyrosine and Diiodotyrosine by means of Modified Charcoal, 177
Pineaioma : a Variety of Argentaffinoma ? (I. Costero, Rosario Barroso-Moguel and K. M. Earle), 190
Pinhey, Dr. E. : *Obituary* of Dr. G. Arnold, 429
Pinocytosis in Relation to Intestinal Absorption : Quantitative Aspects of (D. S. Parsons), 1192
Pirie, A., and Kostial-Simonovic, K. : Barium Content of Different Parts of the Choroid of the Bovine Eye, 1007
Piscitelli, A., et *al.* : Radiation Yield of Citraconic and Mesaconic Acids in Aqueous Solution, 594
Pitt, Frances : People of the Forest, *review*, 314
Pituitary Gland of the Rat : Effect of Liver Regeneration following Partial Hepatectomy on the Uptake of Tritiated Thymidine in the (R. M. Nakamura et *al.*), 707
Pituitary Inhibition : Nemasperm and (G. Fachini et *al.*), 195
Pituitary Stalk of the Mouse : Functional Vascular Fields in the (Dr. W. C. Worthington, jun.), 461
Pituitary Transplants in a Teleost Fish : Secretion of Thyrotrophic Hormone by (J. N. Ball et *al.*), 618
Placebo Reactor (J. Parkhouse), 308
Placenta : Localization of Anti-human Growth Hormone Serum within the Human (J. J. Sciarra et *al.*), 1005
Planning, 29, No. 469 : *An Energy Policy for E.E.C.* (Jack Hartshorn), 132
Planning, 29, 29 April 1963, 411
Plant Analysis : Modern Methods of (edited by H. F. Linskens and M. V. Tracey), Vol. 5, *review* by Dr. A. Allsopp, 315
Plant Cell Tissue Cultures : Accumulation of Amino-acids in (R. L. Wickremasinghe et *al.*), 1302
Plant Cuticles : Cutin of (E. A. Baker and Dr. J. T. Martin), 1268
Plant Growth Regulators (Auxins and Auxin Esters) on the Survival of Free Cells of the Ehrlich Ascites Carcinoma : Effects of (Dr. R. D. Schultz and Dr. D. Norman), 260
Plant Hairs (Prof. J. C. Th. Uphof), (Handbuch der Pflanzenanatomie, Band IV, Teil 5), *review* by Dr. K. J. Dormer, 525
Plant Material by Wafer Counting : Determination of Carbon-14 in (J. R. Corbett and C. S. Miller), 1106
Plant Pathogens in Soil : Factors Determining the Behaviour of (Dr. N. T. Flentje), 327
Plant Pathology Field Meeting, thirty-ninth annual, 24
Plant Phenolics Group of North America, third annual meeting to be held, 435
Plant Phenolics Group sympoisum to be held on "Comparative Biochemistry of the Leguminosae", 435
Plant Physiology and Biochemistry : Prof. S. L. Ranson appointed to the chair of, 643
Plant Tissues, Higher : Utilization of Radiosulphate by (S. K. Sinha and E. A. Cossins), 1109
Plants, Woody (*Vitis riparia* Michx.) : Maximum of Starch during Spring in the (J. Eifert and A. Eifert), 825
Plasma : Antihæmophilic Globulin in Frozen (F. Nour-Eldin), 187
Immunoassay of Human Growth Hormone in (Dr. S. M. Glick et *al.*), 784
Plasma Agar : Events associated with Development of Lipid Plaques on (J. T. Weld and W. M. O'Leary), 510
Plasma and Amniotic Fluid : Comparison of Fœtal Pulmonary Fluid with Fœta (B. B. Ross), 1100
Plasma Column without the Application of a Magnetic Field : Slow Expansion of a (P. Avivi et *al.*), 1244
Plasma of the Rat : Absence of Free Iodotyrosines from the (S. Lissitzky et *al.*), 1002
"Plasma Physics", conference on, 540
Plasmalogenic Triglycerides : Occurrence in Egg Yolk of (M. Proštenik and M. Popovič), 1285
Plastic Flow, Reversed, during the Unloading of a Spherical Indenter(K. L. Johnson), 1282
Plastics Industry Fair, The Fourth International, 1044
Platelets in Dissolution of Blood Clots : Role of (A. F. Bickford, jun., and F. B. Taylor, jun.), 610
Plauson, R. A., and Mallory, H. D. : Liquid Explosives with Transparent Detonation Products, 58
Playfair, Sir Edward : Appointed President of the British Computer Society, 1238
Plescia, O. J., and Pontieri, G. M. : Effect of 8-Azaguanine on the Specificity of Antigens synthesized by *E. coli B/r₂*, 191
Pleurobrachia : Movements and Co-ordination of the Ciliary Comb Plates of the Ctenophores *Beroe* and (M. A. Sleigh), 620
Plust, H. G., and Jahn, D. : Possible Use of Gallium as Negative Electrode Galvanic Cells, 806
Plutonium-239 and other Nuclides in Ground-level Air and Human Lungs during Spring 1962 (Dr. R. V. Osborne), 143
Pneumococcus Type XIV Cross-reactivity : A Mucoid Isolated from Bovine Red Cells exhibiting Strong (G. Uhlenbruck and M. Krüpe), 1289
Poikilotherms : Temperature and the Rate of Ageing in (J. Maynard Smith), 400
"Point Defects in Non-Metallic Solids", British Ceramic Society Meeting, 962
Poisner, A. M., et *al.* : Carbamylation of Oxytocin and Arginine-Vasopressin, 69
Poisoning with Amitriptyline : A Fatal Case of (I. Sunshine and J. Bäumler), 1103
Pokorny, Dr. Vladimir : Principles of Zoological Micropalæontology, Vol. I, *review* by Dr. D. D. Bayliss, 942
Polaczek, A., and Halpern, A. : Effect of Electron Donors on the Isotopic Exchange between Aluminium (III), Gallium (III) and Indium (III) Iodides and Alkyl Iodides, 1286 ; Electrical Conductivity of Solutions of Aluminium (III), Gallium (III) and Indium (III) Iodides in Alkyl Iodides, 1286
"Polar Meeting 1963" (German Society of Polar Research), 1238
Polarization of the Background Radiation : Utilization of Increased Sensitivity of X-ray Fluorescence Spectrometry due to (K. P. Champion and R. N. Whittem), 1082
Polarons produced by the Action of Ionizing Radiation in Aqueous Media : Behaviour of (J. J. Weiss), 589
Political and Economic Planning, Annual Report, 645
Polizzi, M., et *al.* : Nemasperm and Pituitary Inhibition, 195
Pollack, S., et *al.* : Reducing Agents and Absorption of Iron, 384
"Pollen Physiology and Fertilization" : International Symposium on, 122
Polonium-210 in Human Tissues : Lead-210 and (R. V. Osborne), 295
Polonsky, J., and Lederer, E. : Piloquinone : a New Phenanthrene-o-Quinone isolated from the Mycelium of *Streptomyces pilosus*, 285
Poly-DL-Serine Derivatives containing Cytotoxic Groups : Syntheses of (M. Szekerke), 280
Polyatomic Molecular Ions : Pre-ionization Phenomena in the Appearance of Some (J. Momigny), 805
Polyethylene Terephthalate : A Secondary Process in the Liquid-induced Crystallization of (L. Cottam and R. P. Sheldon), 902
Polymer Carbons : Electron Spin Resonance in (D. Campbell et *al.*), 1090
Polymer Films : Crystallization of ω-Dicarboxylic Acids in (Dr. H. A. Lanceley et *al.*), 975
Polymer Melts using the Instron Rheometer : Flow Study of (E. Mary Nicholas), 543
Polymer Membrane : Ion Specific (R. Bloch et *al.*), 802
Polymer in an Electric Field : Polymerization of a Thermosetting (R. W. Warfield and M. C. Petree), 67
Polymerization of a Thermosetting Polymer in an Electric Field (R. W. Warfield and M. C. Petree), 67
Polymorphism : Red Cell Acid Phosphatase Variants : a New Human (Dr. D. A. Hopkinson et *al.*), 969
Polymorphism in Living and Pleistocene Populations of the African Land Snail, *Limicolaria martensiana* ; (D. F. Owen), 713
Polymorphism in Silicon Carbide (E. Dow Whitney), 278
Polyoma Tumours in Rats : Transplantation of (M. Vandeputte and P. De Somer), 391
Polyoxymethylene from Solution : Whisker-like Growth of (H. B. van der Heijde), 798
Polypeptide α-Helix : A Reconsideration of the Moffitt Theory : Optical Rotatory Power of the (Dr. S. F. Mason), 139
Polypeptide prepared from Zymosan : A Water-soluble (P. Laland et *al.*), 465
Polyploidy : A Case of Somatic (H. Wallace), 1115
Polyribosome Action during Protein Synthesis : Mechanism of (H. M. Goodman and Prof. A. Rich), 318
Polysaccharide : Immunization against *Cryptococcus neoformans* by Capsular (H. H. Gadebusch), 710
Polysaccharide Fractions and Transformations in Rhizobium (B. A. Humphrey and J. M. Vincent), 927
Polysaccharides in Viscera of Marine Molluscs : Sulphatases and Sulphated (P. F. Lloyd and K. O. Lloyd), 287
Polystyrene Film formed in the Glow Discharge : Dielectric Properties of Cross-linked (M. Stuart), 59

Polystyrene Membranes for Covering Oxygen Electrodes for Use in Tissue (P. F. D. Naylor and N. T. S. Evans), 911
Polythene : Temperature Dependence of Irradiation Damage to (G. Todd and G. A. Wild), 172
Polythene Disks : Micro-culture of HeLa Cells and Human Embryo Liver on (H. Festenstein), 981
Polytyrosine and its Inhibition by Haptens : Delayed Hypersensitivity to a Conjugate of (S. Leskowitz), 291
Polyuridylic Acid and Aminoacyl Transfer to Mammalian Ribosomes (June M. Fessenden and Prof. K. Moldave), 1172
Polyuridylic Acid on the Incorporation of Phenylalanine into Peptide Linkage by Prostatic Ribosomes : Influence of Testosterone and (D. A. Silverman *et al.*), 808
Polyvinyl Chloride by X-ray Diffraction : Mesomorphic and Crystalline States in (Dr. M. Mammi and Dr. V. Nardi), 247
Ponce, F., *et al.* : Production of Erythropoietin by Anoxic Perfusion of the Isolated Kidney of a Dog, 572
Ponnamperuma, Dr. C., *et al.* : Synthesis of Adenosine Triphosphate under possible Primitive Earth Conditions, 222
Pontecorvo, Prof. G. : Fungal Genetics, *review*, 417
Pontieri, G. M., and Plescia, O. J. : Effect of 8-Azaguanine on the Specificity of Antigens synthesized by *E. coli B/ra*, 191
Pool, W. A. : Man and Beast, *review*, 317 ; The History of the Royal Army Veterinary Corps, 1919-1961, *review*, 524 ; The International Epizootics Bureau, Paris, 336 ; (edited by) : The Veterinary Annual, 1962, *review* by Prof. R. Lovell, 312
Popov, V. V., *et al.* : Two Components in the Development of Ray Cataract in Frogs, 1109
Popovič, M., and Prostenik, M. : Occurrence in Egg Yolk of Plasmalogenic Triglycerides, 1285
Population : Study of Several Gene Frequencies in Yugoslav (P. Grünwald and Č. Herman), 830
Porphyrin Metabolism : Diseases of (A. Goldberg and Prof. C. Rimington), *review* by Prof. C. H. Gray, 1222
Portela, A., *et al.* : Cæsium–Choline Interaction on Muscle Membrane, 815
Porter, E. H., *et al.* : Fast-neutron Source for Radiotherapy, 923
Porter, Dr. J. W. G. : Vitamins and Hormones : Advances in Research and Application, Vol. 20, *review*, 1025
Porter, R. W., *et al.* : Sex Differences in the Serum Cholesterol Response to Stress in Monkeys, 812
Posner, I., and Pimental, E. : Further Separation of Iodine, Monoiodotyrosine and Diiodotyrosine by means of Modified Charcoal, 177
Posner, J. B., and Collins, W. E. : Electroencephalogram Alpha-activity during Mild Vestibular Stimulation, 933
Possible Biological Function of Pseudo-cholinesterase (J. W. Clitherow, M. Mitchard and N. J. Harper), 1000
Possible Case of Genetic Assimilation of Behaviour (Dr. N. Moray and K. Connolly), 358
Possible Origin of the Lunar Walled Plain Ptolemaeus (R. G. Strom and Dr. A. Palm), 1052
Possible Transition in the Initiating Mechanism Leading to Electrical Breakdown in Vacuum (Dr. R. Hawley), 978
Possible Turnover of DNA with an Increased 6-Methylaminopurine Content (E. C. Theil and S. Zamenhof), 599
Post, R. L., and Charnock, J. S. : Evidence of the Mechanism of Ouabain Inhibition of Cation Activated Adenosine Triphosphatase, 910
Post-coital Uterine Fluid : A Tumour-inhibitory Factor in the (Dr. R. Stein-Werblowsky), 570
Postganglionic Fibres : Selective Stimulation of Intra-cardiac (B. Lewartowski), 76
Postgate, J. R., *et al.* : Similar Effects of Various Neutral Solutes on the Survival of *Aerobacter aerogenes* and of Red Blood Cells after Freezing and Thawing, 1113
Post-mortem Material : Occurrence of Pseudo-Barbiturates in (J. V. Jackson and B. S. Finkle), 1061
Post-tertiary Speciation in Europe (Prof. P. C. Sylvester-Bradley), 126
Postulated Biosynthesis of Some 'Anomalous' Natural Phenolic Compounds (T. Money), 592
Potassium ? Muscle Biopsy in Man : An Index of Cellular (Dr. C. T. G. Flear and Irené Florence), 156
Potassium-Argon Age Determinations on Some Rocks from the Broken Hill Region of New South Wales (R. A. Binns and J. A. Miller), 274
Potassium induced by Renin : Effects of *d,l*-Aldosterone on Renal Excretion of Water, Sodium, and (H. Croxatto *et al.*), 182
Potato Leafhoppers : Amorphous Tumours induced in Alfalfa by (D. K. Barnes and R. C. Newton), 95
Potato Tubers and Tomato Fruit by Methyl Ester of Indolyl-3-Acetic Acid : Reversal of Gamma-ray-induced Susceptibility to Decay of (P. B. Mathur), 1007
Potato Tubers cultured *in vitro* : Pathogenicity of *Streptomyces scabies* on (C. H. Lawrence and W. G. Barker), 509
Potentiation of the Anti-reserpine Effects of Dihydroxyphenylalanine by Antidepressants and Stimulants (W. R. McGrath and H. J. Ketteler), 917
Poulding, R. H., *et al.* : Trisomy of Autosome 16, 404
Poultry : Nutrition of Pigs and, Proceedings of the University of Nottingham Eighth Easter School in Agricultural Sciences, 1961 (edited by Dr. J. T. Morgan and Dr. D. Lewis), *review* by Dr. A. Eden, 521
Powder Technology, course to be held at King's College, University of London, 747
Powell, Dr. D. W. : Significance of Differences in Magnetization Along Certain Dolerite Dykes, 674
Powell, R. D., and Brewer, G. J. : Hexokinase Activity as a Function of Age of the Human Erythrocyte, 704
Powell, R. G., *et al.* : Hydroxylation of Phenoxyacetic Acid by Stem Tissue of *Avena sativa*, 73
Powell, T. P. S., *et al.* : Olfactory Relationships of the Diencephalon, 710
Powell, T. P. S., and Cowan, W. M. : Centrifugal Fibres in the Lateral Olfactory Tract, 1296
Prall, J. K., and Doidge, P. R. : Electrochemical Properties at the Curie Point, 800
Pratt, D. : Specificity of the Solute Requirement by Marine Bacteria on Primary Isolation from Sea-water, 1308
Pratt, Dr. G. L. : Appointed lecturer in Chemistry, 1044
Prediction of Future Sunspot Cycles (D. G. King-Hele), 226
Predissociation and Perturbation in the Selenium Molecule (L. Herman and R. Herman), 795
Preen Gland of the Goose : Incorporation of Propionic Acid into a Branched-chain Fatty Acid of the (R. E. Noble *et al.*), 600
Pre-Fluvial, Autogeosynclinal Sedimentation in the Namurian of the Southern Central Province (B. K. Holdsworth), 133
Pregnancy : Increase of Trypsin Inhibitor in Serum during (H. J. Faarvang and O. S. Lauritsen), 290
Pregnancy, Production of Ultra-structural Glomerular Lesions resembling those of Toxæmia of, by Thromboplastin Infusion in Rabbits (P. Vassalli *et al.*), 1105
Prehistoric Human Skeletons : Frequency of Spina Bifida Occulta in (D. Ferembach), 100
Pre-ionization Phenomena in the Appearance of Some Polyatomic Molecular Ions (J. Momigny), 805
Preliminary X-ray Analysis of Hæmoglobin H (Dr. M. F. Perutz and L. Mazzarella), 639
Prentice, Dr. J. E. : Sedimentology of some Flysch Deposits, *review*, 519
Preparation of Aluminium Arsenide by a Vapour Phase Transport Reaction (D. E. Bolger and B. E. Barry), 1287
Presence of Ribonucleic Acid in the Initial Yolk Globules of Oocytes of *Aplysia depilans* L. (A. Bolognari and A. Donato), 697
Preparation of Sieves with Microscopic Pore Diameters (W. H. Dobelle and R. K. Witt), 1288
Preservation of the Countryside : Twenty-fourth National Conference, 962
Preservation of Thin-layer Chromatograms (C. S. Knight), 1288
Pressure Temperature Projection of the Three-phase Line of the Gallium Antimony System (J. C. Brice and M. J. King), 897
Price, J. W., *et al.* : Application of Atomic Absorption Spectroscopy to the Determination of Cobalt in Steel, Alloy Steel and Nickel, 371
Priester, Prof. Wolfgang (edited by) : Space Research III : Proceedings of the Third International Space Science Symposium, Washington, 1962, *review* by D. G. King-Hele, 630
Primary and Subsidiary Condon Loci of Molecular Spectra (R. W. Nicholls), 794
Prime, Prof. H. A. : Appointed to the Chair of Electrical Engineering, 430
Primordia in Ferns : Induction of Buds on Older Leaf (Dr. Elizabeth G. Cutter and Prof. C. W. Wardlaw), 985
Principles of Palæontology, 1139
Principles of Zoological Micropalæontology, Vol. 1 (Dr. Vladimir Pokorny), *review* by Dr. D. D. Bayliss, 942
Priorities of Human Responsibility, 336
Probert, D. : Phonon Concept at High Temperatures, 165
Problèmes Actuels d'Ophthalmolgie, II (Dirigé par E. B. Streiff), *review* by R. A. Weale, 1221
Problèmes Actuels de Paléontologie (Évolution des Vertébrés), (Colloques Internationaux du Centre National de la Recherche Scientifique, No. 104, Paris 1961), *review* by Dr. R. J. G. Savage, 107
Problems of Penology (Prof. W. J. H. Sprott), 890
Procedure for Rearing Houseflies (D. Spiller), 405
Proceedings of the First International Symposium on Rocket and Satellite Meteorology (edited by H. Wexler and J. E. Caskey, jun.), *review* by Dr. R. Frith, 729
Proceedings of the International Conference on the Ionosphere 1962, *review* by Dr. R. L. Smith-Rose, 728
Proceedings of the International Conference on the Physics of Semiconductors, Exeter, July 1962 (edited by A. C. Stickland), *review* by Dr. A. A. Shepherd, 946
Proceedings of the International Symposium on Microchemical Techniques (edited by Nicholas D. Cheronis), *review* by Dr. D. T. Lewis, 945
Production of a Cephalosporinase by *Pseudomonas pyocyanea* (M. Jago, A. Migliacci and E. P. Abraham), 375
Production of Erythropoietin by Anoxic Perfusion of the Isolated Kidney of a Dog (E. O. Zangheri *et al.*), 572
Production of Specific Anti-E Autoantibodies in Experimental Iso-immune Hæmolytic Anæmia in Man (J. F. Mohn, R. M. Lambert, H. S. Bowman and F. W. Brason), 705
Production of Ultra-structural Glomerular Lesions resembling those of Toxæmia of Pregnancy by Thromboplastin Infusion in Rabbits, (P. Vassalli, G. Simon and C. Rouiller), 1105
Proflavine : Inhibition of Ribonucleic Acid-Polymerase Reactions by Actinomycin and (Dr. I. H. Goldberg *et al.*), 44
Programming and Utilization of Research Reactors : Proceedings of a Symposium held in Vienna, October 1961, Vols. 1 and 2, *review* by Dr. T. E. Allibone, 208
Progress in Inorganic Chemistry, Vol. 4 (edited by F. Albert Cotton), *review* by Dr. I. R. Beattie, 734
Progress in Materials Science, Vol. 9 (edited by Dr. Bruce Chalmers), *review* by Dr. H. J. Axon, 414
"Progress in the Biological Sciences in Relation to Dermatology", symposium on, 540
Prophyrins by *Rhodopseudomonas spheriodes* : Inhibitory Action of Adenine, Adenine Nucleosides and Nucleotides on the Biosynthesis of (A. Gajdos and M. Gajdos-Török), 1093
Propionic Acid into a Branched-chain Fatty Acid of the Preen Gland of the Goose : Incorporation of (R. E. Noble *et al.*), 600
Prošťenik, M., and Popovič, M. : Occurrence in Egg Yolk of Plasmalogenic Triglycerides, 1285
Protein-binding Properties of Penicillins : A New Approach to Studying the (P. Acred *et al.*), 758
Protein Sub-units as a Mode of Virus Synthesis : Formation of Stable Shells, from (Prof. G. Belyavin and Dr. E. Rowatt), 949
Protein Sulphydryls in Cell Lines of Different Radiosensitivity : Cytochemical measurement of (Dr. O. Caspersson and L. Révész), 153
Protein Synthesis : Effect of 3,4-Dehydro-DL-Proline on Growth and (Dr. L. Fowden *et al.*), 35
Mechanism of Polyribosome Action during (H. M. Goodman and Prof. A. Rich), 318
Protein Synthesis in Human Reticulocytes : a Defect in Thalassæmia Major : Ribosomes Active in (E. R. Burka and P. A. Marks), 706
Proteus morganii Bacteriophages : Host-range of (J. N. Coetzee), 827
Providing Food for Man and Beast (Prof. M. Jones), 890
Prusoff, W. H., *et al.* : Incorporation of 5-Iodo-2'-deoxyuridine into the Deoxyribonucleic Acid of Vaccina Virus, 1310
Pruvost, Prof. P. E. M. J. : Elected foreign member, The Royal Society, Edinburgh, 119
Pseudocholinesterase Variants in Australian Aborigines : Incidence of (W. R. Horsfall *et al.*), 1115
Pseudomonas aeruginosa : Unlinked Loci affecting Related Biosynthetic Steps in (B. W. Holloway *et al.*), 926
Pseudomonas fluorescens : An Inverse Relationship of the Effects of Oxygen and Iron on the Production of Fluroescin and Cytochrome c by (H. Lenhoff), 601
Pseudomonas pyocyanea : Production of a Cephalosporinase by (M. Jago *et al.*), 375
Psychiatry, Three Hundred Years of, 1525-1860 (Richard Hunter and Ida Macalpine), *review* by Lord Brain, 1224
Psychological Function : Cerebral Localization of (Prof. O. L. Zangwill), 887
Psychotomimetics : Central Actions of (D. R. Curtis and R. W. Ryall), 1003
Psychotria bacteriophila : Nitrogen Fixation by the Leaf-nodule Endophyte of (W. S. Silver *et al.*), 396
Ptak, M., and Douzou, P. : Examination of Optically Excited Amino-acids by Electron Spin Resonance at Very Low Temperature, 1092

Ptolemaeus : Possible Origin of the Lunar Walled Plain (R. G. Strom and Dr. A. Palm), 1052
Publications in the Nuclear Sciences, 1963, 645
Puccinia graminis tritici : Systemic or Semi-systemic Infection of Wheat and (M. L. Gattani), 398
Pugwash Conference, in Yugoslavia, 962
Pullet : Isolation of Phosvitin from the Plasma of the Œstrogenized Immature (P. J. Heald and P. M. McLachlan), 487
Pullman, A., and Pullman, B. : Electron-donor or Electron-acceptor Properties and Carcinogenic Activity of Organic Molecules, 467
Pullman, B., and Pullman, A. : Electron-donor or Electron-acceptor Properties and Carcinogenic Activity of Organic Molecules, 467
Pulmonary Fluid with Fœtal Plasma and Amniotic Fluid : Comparison of Fœtal (B. B. Ross), 1100
Pulp and Paper Industries : Wood Extractives and Their Significance to the (edited by W. E. Hillis), *review* by Dr. R. H. Farmer, 732
Purification of Radioactive Foot-and-Mouth Disease Virus (Dr. F. Brown and B. Cartwright), 1168
Purine Catabolism, a Source of Endogenously Formed Urea in Homogenates of Amphibian Kidney (W. A. Brodsky and N. J. Carlisky), 602
Purkinje Cells in the Cerebellum : Inhibitory Synapses on Somas of (Dr. P. Andersen et *al.*), 655
Purkinje Fibres to Non-uniform Currents : Transient Responses of (A. E. Hall and D. Noble), 1294
Purnell, Dr. Howard : Gas Chromatography, *review* by Dr. C. S. G. Phillips, 210
Puromycin : Action of Insulin on the Isolated Rat Diaphragm in the Presence of Actinomycin D and (D. Eboué-Bonis et *al.*), 1183
Puromycin on Cholinesterase Activity of Embryonic Chick Intestine in Organ Culture : Effect of (A. Burkhalter), 598
Puromycin on Morphogenesis in Amphibian Eggs and *Acetabularia mediterranea* : Effects of (J. Brachet), 714
Pye, J., et *al.* : Behaviour of Active Bacterial Antigens during the Induction of the Immune Response, 1257
Pyke, Dr. Magnus : Advances in Food Research, Vol. 11, *review*, 944
Pylorus-ligation Ulcers in the Rat : Reduction by Chlorpromazine of (R. N. Tiede et *al.*), 1296
Pyrethrin I labelled with Carbon-14 into Susceptible and Pyrethroid Resistant Houseflies : Penetration of (B. C. Fine et *al.*), 927
Pyridine Nucleotide/Flavoprotein Level : Mechanisms for Oxidative Phosphorylation at the (Dr. J. A. Baltrop et *al.*), 759
Pyrolysis : Mechanism of Solanesol Breakdown during (J. D. Grossman et *al.*), 661
Pyrolysis–Gas Chromatography : Examination of the Structure of Soil Humic Acids by (B. R. Nagar), 1213

QUAN, P. M., and Johnstone, R. A. W. : Naphthalenes in Cigarette Smoke, 1184
Quantitation of Erythropoiesis (D. Lockner), 390
Quantitative Aspects of Pinocytosis in Relation to Intestinal Absorption (D. S. Parsons), 1192
Quantitative Assay for the Number of Murine Lymphoma Cells capable of Proliferation *in vivo* (W. R. Bruce and H. van der Gaag), 79
Quantitative Estimation and Identification of Barbiturates in Blood in Emergency Cases (Dr. H. V. Street and C. McMartin), 456
Quantitative Relations between Ferritin and Siderin (W. Meier-Ruge, G. Beneke and G. Ahlert), 175
Quantitative Relationships in Tumours induced by a Virus, and by other Agents (Prof. H. F. Blum), 155
Quantitative Spectrophotometric Determination of Indolyl-3-acetic Acid (R. A. Fletcher and S. Zalik), 903
Quartz using the Point-counter : Petrofabric Analysis of (A. G. Milnes), 445
F_2 Quartz Veining in the Manx Slate Series (A. Simpson), 900
Queen Maud Land : Age Measurements of Antarctic Rocks (P. Pasteels and Sarah Deutsch), 996
Queen Perception by Honey Bee Swarms (J. Simpson), 94
Quesnel, Dr. L. B. : The Bacteria : A Treatise on Structure and Function, Vol. 3, *review*, 4
Quesnel, V. C., and Roberts, J. B. : Aromatic Acids of Fermented Cacao, 605
Quinacillin : a New Penicillin with Unusual Properties (Dr. H. C. Richards, Dr. J. R. Housley and Dr. D. F. Spooner), 354
Quon, Prof. J. E., and Grieves, Prof. R. B. : Chemical Alteration of Urine, 114

RABAN, P. : Adsorption Chromatography of Direct Azo Dyes, 596
Rabbit : Acetylcholinesterase Activity of Capillary Blood Vessels in the Central Nervous System of the (Lt.-Col. J. C. Crook), 41
Effect of Melanocyte-stimulating Hormone on the Eye of the (K. Dyster-Aas and C. E. T. Krakau), 76
Rabbit γ-Globulin Molecules Genetically Defined at Two Loci : Distribution of Allotypic Specificities among (Dr. S. Dray et *al.*), 52
Rabinowitz, D., and Zierler, K. L. : Metabolic Regulating Device based on the Actions of Human Growth Hormone and of Insulin, Singly and Together, on the Human Forearm, 913
Rabinowitz, Dr. M., et *al.* : Inhibition of Ribonucleic Acid-Polymerase Reactions by Actinomycin and Proflavine, 44
Racemic Pteridine during Paper Chromatography : Resolution of a (A. Albert and E. P. Serjeant), 1098
Races of Man (Sonia Cole), *review* by Dr. D. F. Roberts, 731
Radiation at Different Altitudes : Simultaneous Sampling of Cosmic (V. D. Hopper et *al.*), 271
Radiation Damage to Organized Tissues : Dose-effect Relationships for (J. F. Fowler et *al.*), 253
Radiation from 3C273 : 21-cm Absorption of the (B. J. Robinson et *al.*), 990
Radiation from Jupiter at 178 Mc/s. (J. F. R. Gower), 1273
Radiation Hazards in Perspective, 30
Radiation Protection : Freeze-drying and (A. M. Cook et *al.*), 194
Radiation Protection Norms (Organization for Economic Co-operation and Development), 960
Radiation on Transistors in the First *Telstar* Satellite : Effects of (D. S. Peck and E. R. Schmid), 741
Radiation Yield of Citraconic and Mesaconic Acids in Aqueous Solution (A. L. Fantola, E. Lazzarini and A. Piscitelli), 594
Radicals : Isomerization of 1,2-dichloroethylene induced by Chlorodifluoromethyl Radicals : Formation of Metastable (H. Derbyshire and C. R. Patrick), 68
Radicals in the Gaseous Phase : Reaction of Phenoxy Radicals with Methyl (M. F. R. Mulcahy and D. J. Williams), 76
Radio and International Geophysical Research (Dr. R. L. Smith-Rose), 11
"Radioactive Analysis of Water and Effluents", three-day course on, 540
Radioactive Chemicals, Labelled Compounds and Radiation Sources (S. Weintroub), 1240
Radioactive Fall-out Following 1961 U.S.S.R. Tests : Studies of (Dr. A. Walton et *al.*), 526
Radioactive Fall-out Particles during the Year 1962 : Continued X-ray Microanalysis of (M. F. Rajewsky), 162
Radioactive Foot-and-Mouth Disease Virus : Purification of (Dr. F. Brown and B. Cartwright), 1168
Radioactive Products : Radioisotopes, Labelled Compounds, and Radiation Sources (Radiochemical Centre), 1240
Radioactivity of Air Dust, Rain Water and Turf Grass in Bangung, Java (A. Suszkin), 584
Radiobiological Dosimetry (International Commission on Radiological Units and Measurements), 1139
Radio-carbon Dates and the Mayan Correlation Problem (Dr. C. H. Smiley), 473
Radiochemical Centre : *Radiochemical Manual*, Part 2 : *Radioactive Chemicals*, 1240 : *Radioactive Products : Radioisotopes, Labelled Compounds, and Radiation Sources*, 1240
Radiochemical Manual, Part 2 : *Radioactive Chemicals* (Radiochemical Centre), 1240
Radio Communication at High-frequencies : Long-distance (Dr. R. L. Smith-Rose), 545
Radio Emission from Flare Star V371 Orionis (O. B. Slee, L. H. Solomon and G. E. Patston), 991
Radiogenic and Atmospheric Argon Content of Tektites (J. Zähringer and W. Gentner), 583
Radioiodine : Biology of (L. K. Bustad), 1142
Radioisotopes and Ionizing Radiations in Entomology (International Atomic Energy Agency), 333
Radiomimetic Compounds : Interaction of Chromatid Breaks induced by Three Different (A. Michaelis and R. Rieger), 1014
Radio Noise : The Measurement of Characteristics of Terrestrial (URSI Special Report No. 7), *review* by J. A. Ratcliffe, 940
Radio Noise of Terrestrial Origin, Monograph on : XIIIth General Assembly of URSI, London, 1960 (edited by F. Horner), *review* by J. A. Ratcliffe, 940
Radio Outbursts : Occultation Theory of Jovian (A. G. Smith et *al.*), 167
Radio Propagation in an Inhomogeneous Ionosphere : Extremely Low-frequency (R. Burman and R. N. Gould), 581
Radio Research 1962 (Dr. R. L. Smith-Rose), 1046
Radiorubidium by Saliva in Rats after Whole-body Irradiation : Changes occurring in the Excretion of (M. Rakovič et *al.*), 1008
Radiosensitive Molecular Weight of Single-stranded Virus Nucleic Acids (Dr. W. Ginoza), 453
Radiosensitivity : Cytochemical Measurement of Protein Sulphydryls in Cell Lines of Different (Dr. O. Caspersson and L. Révész), 153
Radio Source with a Very Unusual Spectrum (J. G. Bolton, F. F. Gardner and M. B. Mackey), 682
Radio Sources : Change in Rotation Period of Jupiter's Decameter (J. N. Douglas and H. J. Smith), 1080
Radio Sources at Centimetre Wavelengths : Measurement of (R. G. Conway), 1177
Radio Stars : Angular Size of (V. I. Slish), 682
Radiosulphate by Higher Plant Tissues : Utilization of (S. K. Sinha and E. A. Cossins), 1109
Radiotherapy : A Fast-neutron Source for (R. J. Berry, R. Oliver and E. H. Porter), 923 ; (P. D. Lomer and D. Greene), 923 ; (J. F. Fowler), 923
Influence of Fractionation on Clinical Response and Dosage in (J. A. C. Fleming and G. Wiernik), 924
Radio Wave Propagation and the Ionosphere (Ya. K. Al'pert), *review* by J. A. Ratcliffe, 940
Radio Wave Propagation in the Troposphere, Monograph on : Proceedings of Commission II on Radio and Troposphere during the XIIIth General Assembly of URSI, London, 1961 (edited by J. A. Saxton), *review* by J. A. Ratcliffe, 940
Radio Waves from the Equatorial *F* Region : Back-scatter of (B. R. Clemesha), 797
Raekallio, J. : Histochemical Demonstration of Monoamine Oxidase in the Earliest Phase of Wound Healing, 496
Raisman, G., et *al.* : Olfactory Relationships of the Diencephalon, 710
Rajewsky, M. F. : Continued X-ray Microanalysis of Radioactive Fall-out Particles during the Year 1962, 162
Raju, N. V., and Singh, I. : Role of Adenosine Triphosphate in Muscular Contraction, 288
Raju, P. T. : Introduction to Comparative Philosophy, *review* by F. I. G. Rawlins, 519
Rakovič, M., et *al.* : Changes occurring in the Excretion of Radiorubidium by Saliva in Rats after Whole-body Irradiation, 1008
Ram chandra, Dr. G., et *al.* : Evolution of Ethylene by Sub-cellular Particles from Tomatoes as Influenced by Components of the System, 767
Ram Spermatozoa and Penetration of the Ovine Egg : Capacitation of (P. E. Mattner), 772
Raman, S. P., et *al.* : Synthetic Cyclitol Glycoside, 373
Ramel, A., et *al.* : Partial Reversibility of the Ca^{++}-ITP-Contraction of Glycerol-Extracted Muscle, 1154
Ramsay, M. M., et *al.* : Time Characteristics of Light Pulses from Gallium Arsenide Lasers, 1083
Ramsay Memorial Fellowships for 1963-64, 1139
Rand, Dr. M. J. : Annual Review of Pharmacology, Vol. 2, *review*, 210
Randle, P. J., and Garland, P. B. : Effects of Alloxan Diabetes and Adrenaline on Concentrations of Free Fatty Acids in Rat Heart and Diaphragm Muscles, 381
Randolph, M. L., et *al.* : Electron Spin Resonance in Photodynamic Dyes, 243
Rank Organization : G. B. Townsend appointed Manager of the Professional Television Department, 962
Ransom, J. P., et *al.* : A New Reticuloendothelial System Stimulating Agent ('Restim') from Shark Livers, 904
Ranson, Prof. S. L. : Appointed to the chair of Plant Physiology and Biochemistry, 643
Ranvier : Ultrastructure of the Node of (D. N. Landon and P. L. Williams), 573
Rapid Method for Estimation of Iodine-131 in Milk (H. Smith and E. L. Whitehead), 503
Rapid Method for Examining Steam-corrosion and Steam-corrosion Inhibition (L. G. Holmlund), 895
Rapoport, Dr. S. M. : Medizinische Biochemie, *review* by Dr. S. L. Tompsett, 943
Rare-earth Fractionation of Hakhlitic Meteorites and Terrestrial Basalts : Implications of Similarity in (Dr. R. A. Schmitt and R. H. Smith), 550
Rase, H. F., and Hall, J. W. : Dislocations and Catalysis, 585
Rat : Absence of Free Iodotyrosines from the Plasma of the (S. Lissitsky et *al.*), 1002
Rat Liver Ribosomes : Stimulation by Rat Liver Ribonucleic Acid of Incorporation of Amino-acid into (A. Korner and A. J. Munro), 489
Rat Tail Tendon Collagen : Application of the Arrhenius Equation to (W. H. Akeson), 185

Urine of Schizophrenic Patients : 3,4-Dimethoxyphenylethylamine and Other Amines in the (M. Takesada et *al.*), 203 ; (A. J. Friedhoff and E. Van Winkle), 204
Urodeles : Phototaxis and Green Rods in (W. R. A. Muntz), 620
Use of Complex Ions in the Efficiency Tracing Methods for the Standardization of Pure Beta-emitting Nuclides (T. J. Gorsuch, D. J. Jenkins and C. A. Ludbrook), 368
Use of Long Cavities for Aqueous Samples in an Electron Spin Resonance Spectrometer (Dr. T. H. Wilmshurst), 477
Use of Oxidized Proteins in the Examination of Immunochemical Specificity in Delayed Hypersensitivity to Hapten-Protein Conjugates (S. Leskowitz), 85
Use of Paper Impregnated with Esters of *O*-phenylphenol to Reduce the Rotting of Stored Fruit (Dr. R. G. Tomkins), 669
Uterine Blood and the Œstrous Cycle : Flow of (I. J. Kopin and R. J. Wurtman), 386
Uterine Fluid : A Tumour-inhibitory Factor in the Post-Coital (Dr. R. Stein-Werblowsky), 570
Uterine Muscle Transplant to differentiate Myometrial and Vascular Activity : Use of Ear Chamber with (W. J. Cliff et *al.*), 399
Uterine Secretion of Phagocytosis : Influence of Isolated Components of the (Jean Killingbeck et *al.*), 255
Utilization of Increased Sensitivity of X-ray Fluorescence Spectrometry due to Polarization of the Background Radiation (K. P. Champion and R. N. Whittem), 1082
Utilization of Radiosulphate by Higher Plant Tissues (S. K. Sinha and E. A. Cossins), 1109
Uyeda, S., and Hôrai, K. : Terrestrial Heat Flow in Japan, 364

VACCINIA Virus : Incorporation of 5-iodo-2'-deoxyuridine into the Deoxyribonucleic Acid of (W. H. Prusoff et *al.*), 1310
Vaccinia Virus and Cells in Primary and Continuous Culture : Interaction of (M. Nishmi and H. Niecikowski), 1117
Vaccinia Virus Infection on HeLa Cells : Actinomycin D and (A. J. Shatkin), 357
Vacuum : Possible Transition in the Initiating Mechanism Leading to Electrical Breakdown in (Dr. R. Hawley), 978
Vacuum Measurements : Units in (F. T. Worrell), 476

BRITISH RAILWAYS AND THE PROBLEM OF REDUNDANCY

AN important section in the report of the National Economic Development Council, *Conditions Favourable to Faster Growth**, is that dealing with mobility and redundancy. This is of particular interest in view of the extent to which redundancy is proving a major obstacle to the acceptance of the basic recommendations of the Beeching Report† on *The Reshaping of British Railways*, though it is the comparative scale of redundancy involved rather than its actual necessity that sharpens the issue. It is clear enough from the Council's Report that redundancy is inevitable if the development necessary for the growth of Britain's economy is to be carried out, that measures to facilitate mobility of labour and avoid the hardship of redundancy will be essential. To some extent redundancy can be avoided by forward planning of labour requirements, and the inquiry carried out by the Council suggested that it would be feasible to invite industries to make regular long-term forecasts of their manpower requirements by types of skill to provide a basis for planning apprenticeship, adult training and redeployment programmes.

This essentially is what is done in the Beeching Report, and this section of the Report on the growth of the economy indicates the many factors which affect the geographical mobility of labour, some of which, like housing, lie outside the scope of industry itself. Here local authorities could help considerably. It is suggested that a special 'industrial mobility' housing subsidy scheme might be worked out to provide a stronger financial incentive for local authorities to build houses for transferred workers, and to extend the system of granting certificates of housing needs to 'key workers' to cover suitable unemployed workers willing to transfer to growth areas—subject to the approval of the Ministry of Labour. The non-transferability of pension rights continues to be a serious obstacle to the mobility of higher-grade staff. Although the Government has now made the preservation of pension rights at a minimum level on transfer of employment a condition of contracting out of the Graduated Pension Scheme, the Council suggests that the preservation of pension rights on transfer of employment might well be made a condition of approval of a pension scheme by the Inland Revenue.

The Report also contains some suggestions for dealing with the financial hardship of redundancy. The unemployment benefits given under the National Insurance Scheme are much too low in relation to earnings to offer adequate financial protection against redundancy, and the railways are a striking example of the limits in practice to redundancy schemes on an industry-wide basis. They could not deal satisfactorily with a declining industry without assistance from the Government. The Report suggests that there is much to be said for replacing the existing National Insurance Scheme by a comprehensive wage-related contribution and benefit scheme. However, although the high level of benefit in relation to earnings which would then be practicable would substantially reduce the financial hardship of unemployment, such a fundamental re-organization of the existing system could not be achieved quickly. Public opinion would have to be prepared for the change, and the complex financial and administrative problems of a graduate scheme would require examination in detail. Meanwhile, the methods of improving arrangements for dealing with redundancy are being studied by the Ministry of Labour, by the employers, nationalized industries and Trade Unions on the Minister's National Joint Advisory Council. The debates in Parliament on the Beeching Report showed that the Government have the railways particularly in mind in the new arrangements for industrial training, etc. The Beeching Report, as has already been noted, raised the issue of redundancy in two particular sections, and its foresight and planning are manifestly in line with the recommendations which the Acton Society Trust based on a survey of redundancy some five years ago. It was rather on the Government responsibilities in this field that criticism on the debate centred, and here the replies from the Government side suggested that the Government is fully aware of, and responsive to, the recommendations made by the Acton Society Trust relating to the role of the Government in redundancy generally.

Railway costs are predominantly incurred on a time basis and more than 60 per cent of the total is the cost of providing manpower. There are real opportunities for savings by increasing the effectiveness with which men and equipment are used, and apart from closer control of maintenance practices, and the elimination of older types of wagon and coach, rationalization of the workshops offers savings in standing charges estimated at £4 million by 1966. Expert consultants in mechanical handling have been enlisted to study methods of handling and carrying parcels and freight sundries, and the rationalization of specifications for equipment, materials and stores is also expected to offer considerable savings.

These and other measures for increasing efficiency are expected, with the closure of lines and rationalization of traffic, to lead to some considerable reduction in the staff employed on the railways which, it should be noted, has already been reduced from 648,740 in 1948 to 474,538, the largest annual reduction being 25,896 in 1962. These reductions have hitherto been effected with less widespread disturbance than might be expected because there is a high natural wastage of staff and a total replacement rate of about 88,000 a year. It is estimated in the Report that closure of the passenger services as proposed will render some 16,200 staff redundant and a further 10,900 when the lines are later closed completely, while a further 8,600 supervisory clerical and handling staff may become redundant with in the longer term a 4,900 train-operating and maintenance staff.

The average rate of reduction in implementing the proposals of the Report is not expected to be much higher than that in 1962, and the existence of a clear-cut plan will facilitate the strict control of recruitment, which with the high natural wastage will keep the rate of discharge far below the annual reductions in manpower. The pattern of staff displacement and the geographical distribution will not, however, match the pattern of wastage, and

* National Economic Development Council. *Conditions Favourable to Faster Growth*. Pp. v+54. (London: H.M.S.O., 1963.) 4*s*. net. See also *Nature*, **198**, 1123 (1963).

† British Railways Board. *The Reshaping of British Railways*. Part 1: Report. Pp. ii+148. Part 2: Maps. (London: H.M.S.O., 1963.) 20*s*. net. See also *Nature*, **198**, 1233 (1963).

problems are bound to arise from the necessity for extensive redeployment of people. The Railway Board is keenly aware that the reorganization proposed is bound to cause hardship to some people and inconvenience to many others, but it has already shown that it is prepared to ameliorate these difficulties so far as possible. The established arrangements for redundancy have been revised and men who have to move from their appointed post to another in a lower grade will, in future, retain their old rate of pay for up to five years, unless they can be re-instated in their former grade in the meantime. If they have to move home there are substantial payments to meet costs of removal. For those who are discharged or elect to leave rather than move to other work there will be adequate periods of notice and substantial resettlement payments which have been agreed with the Railway Trade Unions. In addition, efforts will be made to help men to find new employment, using existing machinery for placement and retraining and consultation with other employers.

This issue of redundancy was, of course, prominent in the debate in the House of Commons and, for the Government, Mr. Marples, who endorsed the comment of the 1960 White Paper that if the railways were to regain solvency and provide a fair livelihood for their workers, efficiency of operation and the most economic use of manpower were crucial, and Mr. J. Boyd-Carpenter both agreed that it was a major issue. Furthermore, they indicated that the right policy was to ensure so far as humanly possible that those whose lives were affected by the inevitable changes were taken care of and helped. In the Lords debate it was almost the dominant issue, and Lord Robertson was only one of several speakers who warmly praised the Railway Board for its sense of responsibility and the example it had set to other industries. Lord Robertson referred particularly to the retraining scheme started to facilitate movement within the industry and to the appointment of a senior officer to watch over the whole business. Lord Robertson's outstanding speech was concerned essentially with this issue, and he drew from Lord Hailsham the agreement that the Government had a duty to set an example as employer and from the Earl of Dundee the assurance that the Government would do its best to see that men who had to leave the railways were trained for, and placed in, new jobs as soon as possible and without suffering hardship in the meantime.

It is clear that Mr. Marples was fully justified in saying that the extent of redundancy had been greatly exaggerated, and that if the men concerned accepted another job the number of redundancies would be small. Transfer, however, in the railway system may not be a simple matter from the human point of view as was fully recognized in the Parliamentary debates. The Earl of Dundee on the Government side pointed out specifically that the redundancies were not all in one place and that it was physically not possible to fill every vacancy which is caused by natural wastage by moving in a man who had lost his job in another area. Furthermore, the Earl of Dundee expressed the hope that, as Lord Robertson had urged, if it were necessary for an employee to find a job outside the Railway Board altogether, as much care would be taken in helping him as was taken when a soldier was discharged from the Army. He added that the director of resettlement appointed to ensure that all the resources of the railways and the Ministry of Labour were made available to assist men to find other employment and to maintain contact with other employers and with the Trade Unions was Mr. D. Robertson, the Board's present director of establishment and a past president of the Scottish Trades Union Congress.

No unprejudiced reading of these Parliamentary debates or of the Beeching Report itself can leave any doubt as to the sincerity and extent of public concern with the human aspects of this problem of redundancy in the railways or elsewhere for that matter, nor, equally, that anything is to be gained by postponing the issue on the railways. There must, however, be a readiness on all sides to face change and to prepare for it. The Beeching Report at least sets an example in the way in which it is possible to plan for change and to prepare to deal with it in this field of human relations.

SCIENCE IN THE SIXTEENTH CENTURY

Science and the Renaissance

By W. P. D. Wightman. Vol. 1: An Introduction to the Study of the Emergence of the Sciences in the Sixteenth Century. Pp. xv+327+8 plates. Vol. 2: An Annotated Bibliography of the Sixteenth-Century Books relating to the Sciences in the Library of the University of Aberdeen. Pp. xix+293+8 plates. (Aberdeen University Studies Nos. 143 and 144.) (Edinburgh and London: Oliver and Boyd, Ltd., 1962. Published for the University of Aberdeen.) 42*s*. net each volume.

PROF. WIGHTMAN explains that his book originated in a purely bibliographical survey, the first volume being intended as an introduction to the second, "the kernel of the work", a catalogue of early printed books on scientific subjects in Aberdeen University Library. This second volume, which describes 759 separate titles with full annotations, will be of great interest to those engaged in research on the Renaissance antecedents of the seventeenth century Scientific Revolution, in so far as they can be found in the printed literature of the time. In the nature of things, it could not be an all-inclusive bibliography of all the early books on scientific subjects, and many important works are absent from the list. However, much useful information is provided in the material available at Aberdeen, including many works which are both rare and of considerable historical importance. We are, moreover, promised a monograph on the contribution of the library's chief benefactor in those early days, Duncan Liddel, the founding father of Aberdonian science. Since it might throw some light on the vexed subject of the dissemination of new scientific ideas, a study of some of the major libraries of this early period would be a very positive contribution. It is not enough to know that an idea was put forward in a certain book: we should also like to know how widely that book was read.

The first volume will clearly attract a much wider reading public, and Prof. Wightman expresses the hope that it will be found interesting by "scientists anxious to discover the relations of their special disciplines to the others which began to separate out at this time". No doubt he would not claim to have attacked all the problems which complicate our understanding of how modern science began to emerge into the light during this century. Rather, he seems to have intended a bio-bibliographical introduction to them, in the nature of George Sarton's *Six Wings; Science and the Renaissance* could well replace that famous study. He has indeed something of Sarton's amiably conversational manner, drawn from a wide reading, and warm sympathy for his subjects, but he is more concerned to reflect on the real significance of this literature and the concepts involved in it.

Since his starting point was a university library, it is scarcely surprising that this "Introduction" shows a distinctly university bias, which may perhaps be a little misleading in a discussion on "the emergence of the sciences in the sixteenth century". Practical activities of every sort are but briefly treated, and often cast in the shade by the loquacious disputations of the learned. All the same, this bias has one excellent consequence. Medicine was the only scientific faculty at the universities, and the obvious profession to attract those interested in scientific research. Botany, pharmacology, comparative anatomy, even chemistry only gradually began to take autonomous shape, and were still essentially ancillaries to medicine, maturing slowly under her protective cloak. This feature of the science of the Renaissance, and indeed long after, is seldom given its rightful prominence. A general historical study written around medicine and medical controversies makes an interesting change from the usual preference for the more dramatic revolution in astronomy and mechanics.

Prof. Wightman sees the Renaissance as an age of gestation, in preparation for the great advances made during the next century. There were few great discoveries in science, but rather a change in values and outlook, "a re-orientation of observation, a reconstruction of the framework in which the idea of Nature took shape. . . . In what does this re-orientation and reconstruction consist? In nothing less than a technique for the reversal of emphasis from subjectivity to objectivity". This is to be Prof. Wightman's master-key and he applies to each of the sciences in turn this concept of a "transvaluation" within the traditional framework, in which the inherited techniques and data continued in use. At times, one may suspect that he expected more of a transvaluation at the outset of some enquiry into a given science than he was actually to find there. Thus, in his chapters on the development of scientific method through the discussions on medical method, and on the furious controversy over the 'chemical' medicaments advocated by Paracelsus, he begins by implying that a tremendous but silent revolution was going on. By the end of these chapters, one feels a little disappointed. The transvaluation seems to have been so hedged about with qualifications that the men of 1600 end up only a fraction more advanced than the men of 1500. Perhaps, after all, university libraries are places too conservative for a real transvaluation.

A. G. KELLER

INTERNATIONAL HORTICULTURE

Advances in Horticultural Science and Their Applications

Proceedings of the XVth International Horticultural Congress, Nice, 1958. Edited by Jean-Claude Garnaud. Vol. 2: Pp. xii+527. Vol. 3: Pp. ix+578. (London and New York: Pergamon Press, 1962.) 400*s*. net per set of three volumes.

THE papers in these two volumes are grouped under headings which are likely to make a wide appeal to horticulturists. In Volume 2 are papers on fruit growing and flower growing, in Volume 3 papers on ornamental trees and shrubs, Mediterranean and sub-tropical plants, plant pathology and disease control, modern techniques and productivity in horticulture, greenhouses and horticultural climatology. Closer inspection of many of the individual papers, however, suggests that they will interest specialists in the subjects under discussion rather than workers in other branches of horticulture. This does not mean that most of the papers are highly technical in nature. A number of descriptive papers are included, like "Developing a New Arboretum" by W. S. Stewart, "The Situation in Horticultural Research in Hungary" by J. Ormos, and "The Horticultural Herbarium" by C. E. Kobuski, together with several general reports of work in progress at experimental stations. But this more general type of paper does not appear to fit well into the very brief form (usually about four pages), which presumably was imposed by the requirements of the conference. There may be interesting points to glean from the articles, but the shortened form can be indigestible for those attempting to broaden their horticultural knowledge.

The papers concerned with experimental work could scarcely show a greater variation in methods of treatment and presentation. Some of the authors have described a relatively small field of study and have presented data to substantiate their conclusions, others have given results in summarized form from larger experimental programmes. Either of these treatments can convey valuable and interesting information, and examples of the contrasting styles are seen in the papers by J. P. Nitsch and T. Visser. Dr. Visser describes his experiments on effects of environmental and physiological factors on the rooting of tea cuttings and presents his quantitative data in the form of graphs, histograms and tables. Dr. Nitsch summarizes progress made in elucidating the physiological and biochemical mechanisms involved in the photoperiodic regulation of growth in woody plants, drawing on results obtained in a number of experimental projects. In some papers the omission of the more detailed results is less acceptable. For example, in the paper by P. K. Ursulenko on "Biological and Physical Foundations of Fruit Bearing in Fruit Trees", the interesting observation is made that stages in the development of trees are marked by differences in amino-acid complement, but there is little elaboration of this and no discussion of evidence on which it is based. Such treatment may have been desirable in the paper read to the conference but detracts from the value of the published *Proceedings*.

The international nature of the conference is very evident throughout, and a number of the contributions are of interest in that they describe horticultural developments in a particular area or country. In the section on fruit growing, for example, there are papers describing the programmes of two experimental stations concerned with fruit tree research in France, the development of fruit growing in the Ukraine, methods used in combating soil erosion in orchards in North Africa and variety trials with raspberries and strawberries in Poland.

While many of the papers describe work which has been aimed at finding immediate application in horticultural practice others are directed towards a better understanding of the physiology of crop plants. Thus in the section on flower growing there are three papers concerned with problems arising in the growing of gladioli. They deal with temperature and light treatment of corms to hasten flowering and with the irrigation and mineral nutrition of the plants. At the other extreme is the paper by T. C. N. Singh and S. Ponniah "On the Effect of Sound-percussions Transmitted Through the Earth on the Growth and Reproductive Phases of Certain Ornamental Flowering Plants". Further papers on flower crops are concerned with effects of light, temperature and nutrition in controlling growth and development, techniques and problems in breeding, and pests and diseases.

The section on horticultural climatology in Volume 3 is noteworthy in collecting together information which is of general interest to the horticulturist and which otherwise might be scattered through the literature. There are three papers on effects of wind and the use of wind-breaks and eight papers concerned with low-temperature injury to crop plants, with discussions of the prevention of frost damage by the regulation of cold-air streams, the use of water sprinkling, and of heaters and blowers in orchards. Further papers are concerned with the relation between rates of crop development and temperature, the measurement of soil-moisture conditions and the geographic charting of plant climatic adaptability.

It was suggested in the review[1] of the first volume of these *Proceedings* that they should be assessed as a work of reference if their high price was to be justified. On this basis the absence of an index, combined with the somewhat illogical grouping of the papers, can be criticized in that it makes the tracing of a particular subject difficult. Papers on diseases of apples appear both in the section on fruit growing and the section on plant pathology, while papers on electrical soil warming are included under flower growing and under greenhouses. Perhaps more serious is the fact that information in some of the papers was published elsewhere as long ago as 1958, the year of the Congress. I myself noted three papers in the section on flower growing to which this applies.

In spite of the criticisms levelled at these volumes they will represent a worthwhile addition to the horticultural library. From them can be derived a view of horticultural research and thought in many different countries and they are a useful source of factual information on many horticultural topics. Whether the two volumes will prove to be of great interest to biologists, as is suggested on the flap of the dust-cover, is more debatable.

G. P. Harris

[1] Harris, G. P., *Nature*, **194**, 223 (1962).

BIOSYNTHESIS IN BACTERIA

The Bacteria

A Treatise on Structure and Function. Edited by I. C. Gunsalus and Roger Y. Stanier. Vol. 3: Biosynthesis. Pp. xv+718. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1962.) 139*s.* 6*d.*

THE fact that this volume is more than 100 pages longer than either of the two previous ones is itself an indication of the enormous interest in and the great fruitfulness of bacterial systems in the elucidation of biosynthetic processes. The bacterial world has become a Utopia for biochemists and this volume will be as much (if not more) welcomed by biochemists as by bacteriologists. There are twelve chapters dealing with every known aspect of synthesis in both 'autotrophs' and 'heterotrophs'. Chapters 1 and 2 survey our knowledge on carbon dioxide fixation, Chapters 3 and 4 on nitrogen assimilation, in 'autotrophs' and 'heterotrophs' in each case. The remaining chapters deal with the synthesis of vitamins and coenzymes, nucleotides, tetrapyrrole, homosaccharides, peptides, cell walls, proteins and nucleic acids, and finally enzymes.

As in Volumes 1 and 2 there are extensive author- and subject-indexes and a wealth of references. More than 2,500 papers are cited (most of these published in the past decade), and numerous headings and sub-headings make reference easy. As a comprehensive survey of the state of knowledge of bacterial biosynthesis this volume cannot be bettered and every effort was made to give an up-to-the-minute coverage at the time of publication. These extracts underline this attitude: "Nitrogen fixation in cell-free extracts has only recently been obtained; information on the requirements and properties of the enzyme systems is now available. Since the data are of recent origin, have not been presented in general form, and reviews covering these enzymatic data are not yet available, this subject will be treated in some detail" (Chapter 3). Chapter 11 (proteins and nucleic acids) ends with three sections entitled "Discussion (1959)", "Discussion (1961)" and "Addendum (1962)". The second of these sections starts, "The period between finishing the script and correcting the galley proofs has seen the publication of over 300 papers relating to the general field which this chapter is supposed to cover and references to some 200 of these have been darned in". The Addendum commences, "The 9 months that have passed since correction of the galley proofs have seen changes and advances that are of fundamental importance to the understanding and interpretation of much that has been written in this chapter". Such is the *tempo* of industry and discovery in the field covered in these chapters.

This volume is also of some interest to geneticists in that the mechanism of heredity must ultimately have a biochemical explanation and there is much which sheds light on the significance of genetic changes, especially in the final chapter. One of the outstanding general impressions obtained by reading this book is the rapidly increasing number of 'vital' processes which may now be performed in cell-free systems, and one gets the feeling that the possibility that man may eventually manufacture living matter from undoubtedly inanimate starters is not so remote after all. Should that day arrive, this volume will have played a part in bringing it nearer.

It is curious how some simple grammatical errors have been overlooked.

L. B. Quesnel

PATHOLOGY IN MAN AND BEASTS

An Introduction to Comparative Pathology

A Consideration of some Reactions of Human and Animal Tissues to Injurious Agents. By G. A. Gresham and A. R. Jennings. Pp. xi+412. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1962.) 84*s.*

MORE than at any previous time, effective methods are being sought, at an international level, to improve the quality of domestic animals and to eliminate diseases to which they are susceptible or for which they are intermediate hosts of human afflictions. This trend has led to closer associations between veterinary pathologists and their counterparts in the field of human disease, thus reviving, in some measure, collaboration of the sort that flourished in the late nineteenth century. The joint authorship of this book is encouraging testimony of such co-operation.

Gresham and Jennings have chosen to deal with their subject primarily on an ætiological basis and have presented it in twelve chapters, all roughly of equal length. The authors state that ". . . the examples we have used to demonstrate specific modes of action (of different pathogenic agents) have been taken from well recognized, common naturally occurring disease processes rather than from the sometimes narrow and artificial field of experimental pathology. Where necessary, however, we have not hesitated to describe . . . some purely experimental conditions if by so doing we could better illustrate the topic . . .". It is on the latter basis, presumably, that there are, happily, included in this volume such important aspects of experimental pathology as the general adaptation syndrome, some experimental oncology, diseases attributable to radiations, immunological tolerance and even aspects of auto-immune diseases and aging. The references to these subjects are not quite up to date; however, the very inclusion of these topics is most gratifying. Similar remarks apply to the inclusion of some electron micrographs at least in one chapter and attempts to direct attention to the nature and significance of modern work on the structure and role of DNA in genetically determined diseases.

On the other hand, it is strange to find so little reference to geographic pathology. In a volume on comparative pathology the peculiar world distribution of many diseases is surely appropriate. This applies, perhaps especially, to many viral and parasitic diseases and to particular neoplasms (for example, childhood lymphomata in Africa; primary hepatic carcinoma) so much better known to-day than previously. Little attention has been directed to the significant role of climatic factors and vegetation in promoting or even localizing the

aforementioned and other diseases to certain parts of the world. References are made almost solely to demographic findings in Britain; to-day, when so much effort is being made to develop international studies and control of disease, a broader approach to disease incidence would be of undoubted value.

The limited attention paid to the causes and mechanisms of congenital anomalies is regrettable in view of the growing awareness of their importance. Likewise, more attention could have been directed to the biochemical basis of many pathological processes, if only to illustrate the progress which may result when resources of more than one scientific discipline are directed towards individual diseases. In this regard, too, an early chapter on modern investigative methods applied to pathology would have been most interesting and helpful, and would have eliminated the need for digressions frequently interjected in the text whenever techniques pertaining to particular topics are explained.

The printing and production of the book are excellent. Line drawings might have been useful to clarify certain topics; closer correlation of clinical and other macro- with micro-photographs would assist the reader. Many of the illustrations would have been made more valuable by more detailed legends; also, at least a few symbols to clarify allusions to items in illustrations would undoubtedly assist the uninitiated.

In this book a welcome attempt has been made to compare, correlate and contrast the causes and range of pathological reactions in man and beasts. The scope of such a project is most ambitious, albeit desirable. But when an attempt is made to encompass so vast a field, experts in certain areas are likely to detect flaws in approach and in details. None the less, there is little doubt that this work has much to offer to students of and workers in human, veterinary and experimental pathology.

T. GILLMAN

FERROMAGNETISM

Ferromagnetismus mit einen Beitrag

Quantentheorie und Elektronentheorie des Ferromagnetismus. Von Dr. rer. nat. Eckart Kneller, von Prof. Dr. rer. nat. Alfred Seeger und Dr. rer. nat. Helmut Kronmüller. Pp. xx+792. (Berlin, Göttingen, Heidelberg: Springer-Verlag, 1962.) Dm. 126.

Microwave Ferrites and Ferrimagnetics

By Dr. Benjamin Lax and Kenneth J. Button. (Lincoln Laboratory Publications.) Pp. xv+752. (New York and London: McGraw-Hill Book Co., Ltd., 1962.) £6 8*s*.

IN 1939 there appeared one of the most remarkable books in the history of scientific literature, Becker and Döring's *Ferromagnetismus*. It had been made possible by active and fruitful research along two distinct and often not very closely related lines. Theoretical work by Heisenberg, Bloch, Slater and Stoner had led to a fairly clear understanding of the circumstances in which ferromagnetism might be expected to occur. Experimental studies on single crystals and their interpretation by Akulov and Becker made it seem likely that all the phenomena of technical magnetization could be accounted for by the strain theory of Becker and Kersten. This book represented the high-water mark of the strain theory and with its aid the authors accounted for technical magnetization in all its varied aspects in one comprehensive flourish of the pen.

Ten years later, and despite the intervention of a major war for five of them, Becker and Döring's book was largely and irrevocably out of date. Néel had exposed serious errors of omission in the original formulation of the strain theory that cast several doubts on its validity. New experimental techniques had appeared; microwave experiments led to the discovery of ferromagnetic resonance, neutron diffraction had raised the status of antiferromagnetism from a speculative suggestion to an established fact, and the development of new materials such as ferrites with their potential application at high frequencies meant that the dynamic characteristics of magnetic materials would need to be understood far more precisely than hitherto. Henceforth, to try and do for ferromagnetism what Becker and Döring had done in 1939 would need not merely scholarship but stamina and a strong nerve.

In his preface to Prof. Kneller's new book Prof. Köster describes the difficulty which faced him in finding an author not merely able but willing to undertake this gigantic task. His labours were not in vain for this new work has qualities not to be found in the existing books on the subject. It is magnificently comprehensive; there can scarcely be a reference, let alone a topic, which is not covered. The early sections include excellent accounts of antiferromagnetism and ferrimagnetism, thermodynamics, anisotropy and magnetostriction, often in considerable detail, and although these are treated from an experimental angle the appropriate mathematical details are given where necessary. All these sections are preparatory to the main account of magnetic domain structure and the theory of magnetization processes in static and alternating fields. Nothing is omitted and the treatment is authoritative.

The courses of technical and intrinsic magnetization have always gone their own ways, largely independent of each other. It is therefore no surprise to find a section described as "Quantum and Electron Theory of Ferromagnetism" included as a supplement and being the combined work of two additional authors. This section—a mere thirty pages long—is really too brief to be anything more than a résumé of existing theories.

There are a few small defects. In the first place the book is already somewhat out of date. This stands out most clearly where the properties of the compound Au_2Mn are discussed without reference to its helical magnetic structure. The absence of a section devoted to the magnetic properties of the rare earth metals, although in line with the author's approach, is nevertheless a serious omission in a book with such an all-embracing title. Theoretical treatments are often given in full but without critical assessment and without guidance as to the range of applicability of the final result. Finally, despite an excellent subject index printed both in German and English the absence of a cumulative name index sometimes makes a topic unnecessarily difficult to locate. These are, on the whole, minor blemishes. No comparable book contains anything like as much information between its covers and this should rapidly become the standard work on the subject.

No slight is intended on Prof. Kneller's excellent book by describing Lax and Button's *Microwave Ferrites and Ferrimagnetics* as a *tour de force*. It is prefaced by a fifty-page history of the development of ferrite materials and their microwave applications. Thereafter the subject is developed *ab initio* with no concession to chronology. The early sections on antiferromagnetism and ferrimagnetism are masterly. Ferromagnetic resonance is treated with a wealth of detail which includes spin-waves and magnetostatic modes, relaxation processes, non-linear effects and instabilities. This is by far the most comprehensive review of ferromagnetic resonance phenomena which has yet appeared. The sections on wave propagation in ferrimagnetic materials, measuring techniques and microwave devices take up rather more than half the book, which, as the back cover is approached, becomes increasingly addressed to the microwave engineer.

It is an awesome fact that most of this book deals with developments which have occurred over the past ten years. In its seven hundred pages there is not a single reference to Becker and Döring yet, somehow, one feels that no injustice has been done. It is the story of Siegfried and the Wanderer all over again.

Isopodes Terrestres

Deuxième Partie. Par Prof. Albert Vandel. (Faune de France, Vol. 66.) Pp. 417–932. (Paris: Éditions Paul Lechevalier, 1962.) 110 NF.

THE welcome appearance of this volume completes Prof. Vandel's account of the terrestrial isopods of France and forms a valuable addition to the series *Faune de France*.

The first volume, published in 1960, was divided into two sections, a general introduction and a systematic part; Vandel (Volume 1, p. 96), in an outline of the classification, divided the sub-order Oniscoidea into two series, tylienne and ligienne, and the latter into three tribes Diplocheta, Synocheta and Crinocheta; of these, the series tylienne, containing the single family Tylidae and the tribes Diplocheta (Family Ligiidae) and Synocheta (Super-family Trichoniscoidea), are dealt with in Volume 1.

The second volume is almost entirely devoted to a systematic account of the French species belonging to the tribe Crinocheta, so it is unfortunate that in this volume the status of the tribe has been reduced to that of a sub-tribe without any explanation being given; this fact is bound to give rise to some confusion since Vandel (Volume 1, p. 95) refers to the characters on which Legrand (1946) established the Synocheta and Crinocheta and gives no indication that the two are not of an equal systematic level. Crinocheta is divided into two super-families, Atracheata and Pseudotracheata; the former contains six families of which four (Stenoniscidae, Tendosphaeridae, Squamiferidae and Oniscidae) are represented in the fauna of France and the latter seven, five of which (Cylisticidae, Porcellionidae, Armadillidiidea, Eubelidae and Armadillidae) include French species.

As in the first volume, super-families, families, etc., are defined and keys for the identification of genera and species are included wherever applicable. Each species belonging to the fauna of France is dealt with under the following heads: synonyms, morphology, affinities, reproduction, parasites, ecology, and geographical distribution; in many cases the descriptions of species are accompanied by excellent illustrations and in some cases distributional maps are also included.

The volume contains a glossary of relevant scientific terms which should prove of real value to the non-specialist reader; there is also an extensive bibliography and a systematic index, which refers to the contents of both volumes.

Applied Dynamic Programming

By Richard E. Bellman and Stuart E. Dreyfus. Pp. xxii + 363. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1962.) 52*s*. 6*d*. net.

DYNAMIC programming is one of the characteristic techniques of modern applied mathematics. Basically it is a synthesis, and extension, of variational calculus and statistical decision theory, and its field of application is the multiplicity of problems covered by the terms 'operations research' and 'automatic control'. This very general technique has been made practicable only by the advent of the electronic computer. The principles have been explained by R. E. Bellman and his collaborators in two previous books and numerous papers, but *Applied Dynamic Programming* is the first systematic exposition of the associated computational methods.

The text is a discussion of a wide range of practical problems together with their solutions; they include the warehousing and inventory problem, the transportation and routing problem, space vehicle guidance and feed-back control. Since the straightforward numerical approach is often beyond the capacity of the largest computer a useful discussion of approximation methods is given. The effectiveness of policy space approximations is brought out, and the exploitation of the special features of particular problems is rightly emphasized. It is disappointing to find that one important approximation method is relegated to a short appendix.

The presentation is refreshingly clear and direct and makes the principles accessible to people who do not enjoy struggling with mathematical refinements. Those already familiar with operations research will find this book a valuable addition to the literature on computational methods, while newcomers will find it a superb introduction to the way that problems are formulated and solved.

J. J. Florentin

Modern Physics

An Introduction to Atomic and Nuclear Physics. By Prof. D. E. Caro, Dr. J. A. McDonell and Dr. B. M. Spicer. Pp. x + 222. (London: Edward Arnold (Publishers), Ltd., 1962.) 20*s*. net.

THIS book describes the principal steps in the development of atomic and nuclear physics from the discovery of X-rays and the electron to the identification of the anti-proton—the topics, that is, which are usually labelled 'modern physics', though one feels that the exclusion from this heading of, for example, recent work on solid-state physics is somewhat arbitrary. The authors are at the University of Melbourne and Monash University and they have aimed their book at first-year students there, but they have also tried to make it useful to students in their last year at school. In a 'blurb' to the English edition the publishers suggest its use in sixth forms, remarking that the book covers all the topics in the modern physics section of the syllabus for the General Certificate of Education Advanced-level Examination, though going farther than the immediate requirements of the examination syllabus.

The authors treat the subject historically in order to show not only what a theory is but also how it was developed. In this they are generally successful. The writing is clear, direct, and unusually free from the clichés of scientific exposition. Some of the headings to sections and chapters have the ring of newspaper headlines (of the more sober sort) but are none the worse for that. An unusual feature in books at this level is the inclusion of references to original papers. Although not detailed or taken to great depth, the discussions are by no means superficial. The book should be valuable to its intended readers and to teachers; it has the additional merit that it is cheap by contemporary standards.

K. E. B. Jay

Structural Geology of North America

By Prof. A. J. Eardley. Pp. xv + 743 (figures). Second edition. (New York: Harper and Row, 1962.) 162*s*.; 21.50 dollars.

WHEN the first edition of Prof. Eardley's text-book appeared in 1951, it was widely acclaimed as one of the most outstanding geological works of recent years, giving the only modern treatment of the structural evolution of North America. In the second, extensively revised, edition seven new chapters have been added, one on Precambrian orogenic belts and six on the igneous provinces of the western Cordillera, thus providing a fuller account of the eruptive rocks than has hitherto been available in text-book form. Fifteen coloured maps depicting the palæogeography of the continent, one for each geological period, have been re-drawn to incorporate recent discoveries. Although the work is specifically addressed to advanced undergraduates in geology, its scope is such that it will be more fully used at the post-graduate level; and, by virtue of its comprehensive character and its readability, it will doubtless long continue to be used as a convenient reference book. Minor misprints are rather frequent and the unorthodox page size (11 in. × 8¼ in.) has disadvantages in a volume weighing 4¾ lb.

INTEGRATION OF CELL REACTIONS

By Dr. A. C. R. DEAN and Sir CYRIL HINSHELWOOD, O.M., F.R.S.

Department of Physical Chemistry, University of Oxford

Introduction

THAT living matter reproduces itself by some kind of copying process has been commonly realized for a long time. That this process depends essentially on conformity of new material with existing spacings in molecular patterns was expressed in the various analogies with crystal growth or template action and in the correspondences pointed out by Astbury[1] between various distances revealed in X-ray analysis. That the sequences of monomer units in proteins, nucleic acids and polysaccharides allow an almost infinite variation in possible patterns has long been obvious. All these ideas have in more recent times been succinctly stated in terms of 'information' and 'coding'[2].

Modern X-ray analysis has focused attention on the helical structure of DNA (deoxyribose nucleic acid), on the great importance of base-pairing in the formation of doubly stranded DNA as a major element in replication, and also on the configuration of protein molecules[3–6]. The ultra-centrifuge has revealed the large range of particle sizes and molecular weights characteristic of the macromolecular cell components, and the use of isotopic tracers has revealed the lability of some of these[7,8]. The correspondence between relatively labile low molecular weight RNA (ribose nucleic acid) and the DNA of an invading phage has led to the conception of 'messenger' RNA, an idea which has been supported by the claim that the low-molecular-weight RNA formed during periods of rapid adjustment of cells to new conditions differs in composition from the normal[8,9].

A further elaboration of the conception of information and coding is represented by the 'repressor', a substance which is supposed to prevent an existing gene from manifesting its effect[10]. The action of the repressor itself is counteracted by the appropriate 'inducer', which allows the repressed gene to express itself in the formation of specific enzymes, previously thought to be called into being by a rather more direct and positive action of the inducer. The essential basis of the repressor idea is that certain substrates or products of an enzyme X may inhibit, not so much this enzyme itself (an action which would be entirely analogous to well-known phenomena of heterogeneous catalysis[11]) as the first member of a whole enzyme sequence by which X is ultimately synthesized[10].

All these various lines of approach represent developments in the quantitative side of biology and as such are highly characteristic of the modern trend. Valuable and indeed spectacular as some of them are, they are in many respects unco-ordinated, and do not yet give a truly quantitative treatment of the cell as a working unit. It seems to us that there is still lacking a proper appreciation of what might perhaps be called the 'total integration of cell function', a principle which we feel is unlikely not to be observed by Nature after countless ages of evolution.

Some Difficulties

The way in which some of the present ideas about cell function seem to us to need enlarging and co-ordinating may first be illustrated by a few examples.

(*a*) Transfer RNA of a given type is supposed to combine specifically with a single amino-acid which it presently guides into the correct position in a peptide chain. Since some twenty amino-acids may be involved, since there are only four possible structures for the terminal base in the RNA, and since the influence of side-chains in organic reactions is seldom transmitted very far from the reactive centre, the specificity can scarcely be explained on purely intramolecular structural grounds. Indeed, the assumption is generally made that the amino-acid–RNA combination is mediated by a specific enzyme[12,13]. If it is, then the specificity of the enzyme protein is playing a no less important part than that of the RNA, and it appears arbitrary to rule that one is more fundamental than the other. Moreover, the general control of all the individual steps involved in the complex polymerization processes to form the macromolecular cell components can scarcely be casually dismissed as operated by 'enzyme reactions' as though the mechanism of each enzymatic stage did not itself present in one form or another the same major problems of specificity, and conformity to an existing pattern. Familiarity with enzyme reactions may breed contempt, or at least a tendency to regard the name as providing an explanation of the mechanism and a failure to realize that activating enzymes are, in the words of Zamecnik[12], "unusual catalysts deserving of more attention than they currently receive".

When RNA and DNA are both built up under the influence of specific enzymes, are we really justified in saying that DNA can affect the cytoplasm and not vice versa? Without the cytoplasmic constituents, the right DNA could not be made at all.

(*b*) The idea of repressor action would, it seems to us, benefit from incorporation into a wider setting. At the moment we have the picture of one gene responsible for the formation of an enzyme which is inhibited by a repressor formed under the influence of a second gene. The effect of the repressor can be neutralized by the action of an inducer which the cell may never have encountered before. Natural selection seems to have allowed a good deal of unnecessary activity to escape elimination for a long time. Inhibition of the actual activity of an enzyme, either by a substrate or by a product of its own working, would be perfectly understandable on the analogy of what is frequently observed with inorganic catalysts. Catalytic action depends on some degree of affinity between the catalyst and the substrate or the product, and this fact means that excess of either may block the surface (for example, SO_3 poisons platinum in the reaction of SO_2 with O_2). 'Repression', however, is assumed to affect not the working of the enzyme itself, but that of quite different enzymes preceding it in a synthetic chain. The normal principles of catalysis suggest no reason for this. The difficulty would no longer exist if the actual functioning of the enzyme were in fact impaired and if this impairment reacted back on the synthesis of its own precursors through a cycle of interdependent reactions in the way which will be dealt with later. Thus here, too, the disregard of the integrated function of the cell leaves unsolved a problem which might in the end prove not to be real. Evolution has in all probability ensured that synthesis and function are seldom completely uncoupled.

(*c*) One may well feel some degree of uneasiness about the failure to qualify statements such as the common one that chloramphenicol specifically inhibits protein synthesis. Protein synthesis is a complex affair with many

stages. If protein is not formed, no enzymatic activity or anything dependent on it can continue for long. All that can be said is that the ratio nucleic acid/protein continues to rise for a short time during the unco-ordinated events following the interruption by this drug of normal cell function.

Interplay of Cell Components

Protein cannot be formed without the mediation of RNA. Neither can RNA nor DNA be synthesized without the necessary specific enzymes. Cells cannot function steadily without periodic division, and cell division is not possible without the production of a cell wall. All these constituents are clearly in mutual dependence.

There may well be a sense in which the DNA may be given the most fundamental role. We may say that an imposed mutation affecting DNA soon transmits its consequences to the other constituents, while changes chemically induced in these will soon disappear provided the DNA code remains intact. Even if this is accepted as beyond all doubt, the working of the cell as a machine cannot possibly be understood except in terms of the interplay and coupling of all its parts. Work on isolated cell reactions or components may yield valuable information; but this can never be properly assembled until the laws of integration of cell function are applied.

Although the contrary might sometimes seem to be tacitly implied, the self-replication of DNA in the absence of other cell components and in particular of enzymes has never been observed. The DNA is, moreover, never continuously replicated except in the intact functioning cell. In cell-free systems its synthesis may proceed to a limited extent, but must then stop.

Since the cell cannot continue to function without periodically dividing, the steady formation of wall material is necessary. The structure of the cell wall, with its complex pattern of polysaccharide, muco- and lipo-protein, is highly specific[14], and indeed probably as specific as that of proteins and nucleic acids. It determines essential permeability relations, and is probably the actual seat of certain enzyme activities. Moreover, the enzymes and nucleic acids of the interior cannot be correctly built up unless the cell wall makes the proper provision for the access of the raw materials. Nor can the wall be maintained and expanded without the appropriate activity of the nuclear and cytoplasmic components. Once again we have the picture of total integration.

Something in a way equivalent to a code resides in the secondary structures constituted by the foldings and spatial distributions of the macromolecular components of the cell. Geometrical factors directly affect the diffusion paths of the many labile intermediate metabolites, and thus may determine the ratio of alternative reactions, and may even affect the probability of incorporation of a given type of unit into a growing macromolecular chain. The equilibrium folding of proteins may, as has been suggested[15], be pre-determined by the amino-acid sequence; but equilibrium does not normally prevail in biological systems. In the last resort the primary DNA code may be able to impose its message on everything else, but it would be rash to reject all consideration of the possibility that an established geometry of diffusion paths, controlling the synthesis of enzymes, polysaccharides and nucleic acids alike, can have no influence at all on its own perpetuation, or in any event on the speed of its own modification. Once again it would seem wiser to remember the principle of total integration.

Some Sources of Misconception

The true perspective of cell phenomena is sometimes disturbed by the way in which experiments are planned.

In crossing and recombination tests a given character is often recorded as positive or negative on the result of an observation made at a single fixed time such as 24 or 48 h. The consequence is to impose an artificial discontinuity which the phenomena do not inherently possess. The appearance of sharp distinctions instead of gradations tends to focus attention on structural differences rather than on continuously varying processes and so gives a false picture of the true relationships. The distinction between constitutive and inducible enzymes[16] is, for example, probably much too sharply drawn. The less information there is, the more clearly defined a classification may appear. Suppose, for example, we have three related enzyme activities all quantitatively and continuously variable. Crude criteria of assessment can easily lead to a matrix of possibilities ranging from + + + to − − − with all other combinations of + and − between. This can be interpreted in terms of single and separate genes. Since the activities are related, they may not separate easily, and a further conclusion may be drawn about the contiguity of the genes on a chromosome. The arbitrary nature of this could easily escape attention.

Complaints have been voiced that genetic data not conforming to clear-cut or preconceived patterns are often discarded[17,18]. Indeed, it must be said that the propounders of genetic theories themselves subject one another to a good deal of criticism, which, taken as a whole, suggests the need for a wider view of the entire field.

Lederberg[19] has pointed out that streptomycin gives exceptionally clear-cut results in the distinction between sensitive and resistant types and has directed attention to the fact that in this respect it is 'unusually suitable'. But the distinction he makes is seldom borne in mind by those who quote and base wide generalizations on the results obtained with this drug (which in fact there are good reasons for regarding as quite untypical[20]).

Another experimental need to which insufficient attention may be paid is that of ensuring a proper steady-state relation between the organisms under test and their environment. A strain of bacteria is sometimes maintained on a nutrient agar slope or in broth for long periods, and then in a matter of hours or minutes after transfer to a defined artificial medium it may be tested for growth rate or enzyme activity, or it may be crossed with another strain as far removed as itself from equilibrium with the environment. Such procedures may give very misleading results unless it is borne in mind that at a first transfer to a new medium the growth rate is low, the enzyme activities are abnormal, and the nucleic acid and protein contents out of balance.

Even when thoroughly acclimatized cultures of known history are used, variations in nucleic acids and proteins occur during the growth cycle[21,22] (a completely steady state being reached only in continuous culture[22–27]) so that snap tests taken at a fixed time may be completely unrepresentative.

Even if minutely standardized procedures are laid down, it may still be true that the results are an unspecified function of the experimental conditions and will be difficult to assess unless this function is itself investigated.

The present-day picture tends to be fragmented, static, and in some respects artificially simplified. The cell is often spoken of as though it were an unco-ordinated collection of mechanisms. 'Regulator genes' are spoken of as being switched on and off; but what are regulator genes and repressors if not part of the expression of the total quantitative cell balance ?

The structural code, at whatever level it may be inscribed in the cell, controls the whole set of potentialities. The expression and balance of these are governed by certain general principles which cannot be ignored without resulting confusion.

A number of communications on the kinetics of cell and tissue growth have been published at different times[28–35]; but it may be said on the whole that their influence needs re-asserting.

Integration of Cell Processes

The 'principle of total integration' is capable of mathematical expression. If the rate of formation of a nucleic acid, A_1, depends on an enzyme reaction, we should have in the simplest case $dA_1/dt = k_1P_1$, where P_1 is the concentration of the appropriate enzyme. Conversely if the protein formation is guided by a nucleic acid template, we should have another equation such as $dP_1/dt = k_1^1A_2$. The general principle is unaffected by the consideration that the individual equations are not necessarily of the simple linear form given in the example. Having regard to the active part that the cell wall plays in permeability phenomena as well as being the seat of certain enzyme activities, the polysaccharide, mucopeptide and lipoprotein constituents can all be brought into the scheme.

Now since the cell reproduces itself as a whole, and no part can continuously function without the others, it is reasonable to express the integration principle by closing the set of equations according to a scheme of which the following is the simplest example:

$$dX_1/dt = k_1X_2,\ dX_2/dt = k_2X_3,\ dX_3/dt = k_3X_4 \ldots \ldots\ dX_n/dt = k_nX_1$$

Great elaboration of such schemes, with complicated branchings, is, of course, possible, without change in the basic principle[29].

A second principle, without which no satisfactory theory of cell function is possible at all, is that of the preservation of physico-chemical balance. Inflow of nutrients and outflow of waste products in general can only maintain a proper balance within certain limits of cell size. Hence the necessity for division. Control of division must rest on a third principle, namely, that of some degree of coupling between the act of division and the process of growth. Many factors may be involved in this[36-40], but one simple overall formulation of the condition would be that division occurred when the amount of some key component in the cell reached a critical value[28-30,37]. More elaborate specifications could be laid down without changing the essential need for some such coupling condition. These could bring in reducing potential, size of nuclear particles and so on. The main point is, however, that without some attempt at a formulation no theory can have contact with reality.

Systems of equations based on the foregoing principles have already been examined. They are, it should be emphasized, in no way in conflict with the idea of genetic codes or any other legitimate conceptions of genetics. They lead to some general conclusions which the theory of cell function cannot properly ignore.

The cell emerges as a system which automatically adapts itself to give the optimum growth rate in a given medium. In so doing it changes the proportions of its components, and when it is transferred from one medium to a fresh one it may abandon one pattern of chemical reactions for another. In the process it brings itself into an optimum relation with its environment[29,30].

It is legitimate enough for particular purposes to talk of genes, operons, cistrons, repressors, messenger and transfer RNA, ribosomes, and so on, as parts of a fragmented and often virtually static system; but it is only when they are assembled into a machine that they can possibly make complete sense. When the assembly is ignored, the need will often arise to explain each new fact by a fresh *ad hoc* hypothesis.

It is the actual coupling of the assembly which is responsible for the very important cell property of adaptability to optimum growth, and for the existence of whole continuous ranges of properties rather than discrete differences only. In drug resistance phenomena, for example, although the resistant forms may on occasion show a single degree of response whatever the concentration of drug to which they have been exposed (selection of pre-existent types)[20], they more often display a continuous spectrum of degrees of resistance[30].

We shall not re-capitulate here all the experimental evidence for direct adaptation[30,41-48] nor the objections to the fluctuation test[49] which have been claimed to disprove it. The isolated demonstration (by replica plating) of pre-existent forms resistant to bacteriophage and to relatively low concentrations of streptomycin has, as mentioned here, led to the quite illegitimate assumption that the result is general.

Drabble and Hinshelwood[20] showed that adaptation and mutation occur together in the case of streptomycin resistance, and Kilkenny and Hinshelwood[50] showed that even yeast cells which segregated in a Mendelian manner still underwent direct adaptation (to galactose) after separation.

The examination of the growth equations shows, furthermore, that in a given environment the establishment of a true steady state may be fast or slow[25]. Correspondingly, adaptive changes may be rapidly or slowly reversible. This result corresponds with experimental observations that adaptations are sometimes easily reversible and sometimes persistently held[30], the notion of stable heredity with unicellular organisms being one of degree only. The argument based on stability that adaptive changes are purely selective cannot be consistently upheld. Cells with greatly changed characteristics, relating, for example, to fermentative and respiratory properties and to drug resistance, can be obtained under conditions which preclude any important degree of selection of special types of individual[47,48,51-56]. The importance of enzymatic differences in a directed antigenic transformation is stressed by Austin, Widmayer and Walker[57] and the interplay of microbe and environment in clinical practice is discussed by McDermott[58].

Those who, rightly, lay great stress on the principle of natural selection sometimes fail nevertheless to understand that the selection of an appropriate reaction pattern by self-replicating matter is just as effective and, therefore, may be just as important as the selection of special individuals. A preference could only be justified by some kind of exaltation of structure over function, a distinction which Nature is unlikely to observe.

Unbalanced Growth

A good deal of importance is attached in the literature to observations about the differential synthesis of cell components, for example, uneven replication of DNA at different phases of individual cell cycles. The observations on this seem to have been made entirely with cells not in dynamic equilibrium with their environment. The cells have, for example, been deprived of special growth requirements such as thymine[59], very recently transferred to a new medium[59], or subjected to temperature shock[60]. In these circumstances, the principles we have outlined here would predict very severe disturbances of the co-ordination between the synthesis of different components. To take the most highly simplified example possible, suppose :

$$dX/dt = \alpha Y$$
$$dY/dt = \beta X$$

In dynamic equilibrium X and Y will settle down to average values of X_0 and Y_0 per cell. Suppose we transfer to a medium where the X component (say an enzyme) functions poorly, then the rate of formation of Y is reduced very greatly (possibly to zero), while the formation of X for some time can continue at the original rate. It would be wrong to infer from this that the replication of X necessarily and naturally is a temporal antecedent of that of Y. When continuous growth is allowed again, the proportions will eventually settle down to a balanced ratio. How contingent the whole phenomenon must be is shown by the fact that disturbances in relative synthesis rates characterizing growth of 'synchronous'

cultures has proved to be a function of the way in which the synchronization is effected[27,61,62].

Significance has been attached to the observation that in some synchronized cells mass may increase linearly instead of exponentially with time. Quite apart from the question whether the distinction can be accurately established for the small changes in mass involved, any cell thrown right out of balance can show anomalous rates of increase for any components. With a more carefully planned technique of synchronization (depending only on the selection by filtration of appropriately sized cells and not subjection to chemical or temperature shock) synchronized cells can be obtained in which RNA, DNA and total protein all increase exponentially and maintain a constant ratio over the whole cell cycle[27,61].

Experiments in which the formation of protein or nucleic acid, or the course of specific enzyme activities, is followed for short periods after disturbances such as the addition of drugs are extremely difficult to interpret in the absence of much more complete studies. If a motor-car factory were partially destroyed by a bomb, finished cars might continue to be delivered for a short time, or alternatively individual components might pile up. But conclusions about the sequence of the manufacturing process could be drawn only by the careful co-ordination of various kinds of information.

Conclusion

Although some of the ideas about cell integration put forward in this article have received a good deal of opposition they are supported by much that can be found in the literature.

A very positive attitude is adopted not only by Graham Cannon[63] but also by Uvarov[64], who says: "In spite of a number of cases when environmentally induced variations have been shown to be, at least temporarily, inheritable, there is a reluctance to accept any evidence that might appear to favour the much maligned Lamarckian principle" . . . (and) . . . "this should encourage more entomologists to study their problems without being afraid of infringing some outdated canons of text-book genetics". Ephrussi[65] has remarked: "The second thing we should avoid is basing the distinction of mechanisms on nuclear or cytoplasmic localization. In my opinion this has been a major source of confusion in the past, and it is not going to be so easy to avoid it in the future because we have all been trained to regard the problem of differentiation as a nucleus/cytoplasm dilemma". Danielli[66], commenting on this, refers to: "evidence of either nuclear or cytoplasmic control, or both, in relation to structure and function". Our belief is that the relation needs to be made more explicit.

A common attitude is to admit the possibility of direct adaptive changes in principle but to ignore, dismiss or minimize the significance of the evidence that they occur[67–70]. When this is done the picture of cell function is left very incomplete.

Some authors speak occasionally of specifically induced mutations[71]. They accept the directing influence of the environment on what must, according to the accepted view, be the DNA code. The change in the DNA must involve enzyme action at some stage, so that the distinction between this kind of mutation and an adaptation becomes very indefinite. In this connexion we may refer to the gradual stabilization of induced enzyme adaptation which is observed with bacterial cultures[72,73] and also point out again the arbitrary nature of the distinction between inducible and constitutive enzymes.

Biologists concerned with the differentiation of tissues in complex organisms seem to take a wider view of the potentialities of the cell. Weiss[74], for example, says that: "genic replication, while seemingly the initiating step in the growth process, is followed by chains of events the nature of which is determined by the specific constitution of the (extragenic) rest of the cell". He also says[75]: "In short, the story of the molecular control of cellular activities is bound to remain fragmentary and incomplete unless it is matched by knowledge of what makes a cell the unit that it is, namely, the cellular control of molecular activities". Sonneborn[76] refers to: "successive cycles of differentiation of cytoplasm by nucleus and then of nucleus by cytoplasm". Chantrenne[77] says: "For if the cytoplasm in bacterial systems appears ancillary in regard of the all-mighty genome, embryologists view the cells and embryos as a much more involved system in which the cytoplasm exerts a very strong control on the genome". These authors are concerned with systems much more complex than those in which the kinetic implications can be easily treated but their basic ideas certainly seem to agree with the concept of cell integration.

Perhaps, if all that has been said in this article is conceded, its relevance to the discussion of other modern work may still be questioned. Our contention is that intensive work on individual fragments of a complex machine is not only incomplete but also may be misleading unless attention is paid to the way in which the parts fit together. Coding, information, messengers and carriers are all perfectly valid conceptions: so also are various kinds of enzyme-mediated condensation reaction. But these terms have in themselves little explanatory value, and present-day ideas will only achieve maximum fruitfulness when so combined that they are not left simply to describe bits of a machine without anything to make it work. Sometimes the claim is made that machines can only be understood in terms of their parts. The counterclaim can also be advanced that to understand how the parts fit together the machine must be observed in action. Relatively simple phenomena do reveal the machine in action. Apart from adaptive responses, to which reference has already been made, we have the variation of enzyme contents of cells according to need, enzyme changes compensating for the effects of adverse *p*H, the rise and fall of stores of cell components, and the whole rhythmic variation of cell composition during the growth cycle. One last example may be cited. When cells are multiplying two tendencies may be observed. On the one hand, the DNA content per unit of mass tends to be constant under optimum conditions. On the other hand, the cell tends to divide so as to maintain a constant amount of DNA per cell[21]. When nutrients become deficient a compromise has to be struck: there is an actual increase in the DNA per unit of mass; but a more economical sharing out so that the cells become much smaller and the amount of DNA per cell drops[22]. Facts such as these can only find an explanation in terms of total integration.

It must be emphasized again in conclusion that the ideas we have expressed are in no way in conflict with the conception of the genetic code, nor do they ignore the principle of mutation and selection. Cells in the course of evolution must have profitably exploited the variability of reaction patterns and the consequences of complete integration. It is those who affirm the contrary who fail to give the natural selection principle its due.

RADIO AND INTERNATIONAL GEOPHYSICAL RESEARCH*

By Dr. R. L. SMITH-ROSE, C.B.E.

Vice-president, Institution of Electrical Engineers, London; president, International Scientific Radio Union, Brussels; formerly director of the Radio Research Station, Slough

APART from its direct application to communications and broadcasting including television, and as a vital aid to air and maritime navigation, radio is essential to the practice of telemetry in being the means whereby physical measurements made at a point remote from the observer are recorded and communicated to him. According to the programme of the National Telemetering Conference, we are reviewing the applications of telemetry in such fields as bio-medicine, space electronics and oceanography. In so far as they are concerned with phenomena in the Earth and its surroundings, these subjects fall within the definition of geophysics; and I propose to confine myself to certain aspects of international geophysical research, with which it has been my privilege to be associated for some forty years.

Considering the Earth's atmosphere from the ground upwards, we may conveniently divide it into three regions: (1) the troposphere, or lower atmosphere in which electrical conductivity plays an infrequent and relatively minor part; (2) the ionosphere, that important region of high, but variable, conductivity without which world-wide radio communication would hitherto have been severely limited; (3) the upper, and again poorly conducting region of our atmosphere, which has been one of the subjects of investigation in what we may term the 'space age' using man-made or so-called 'artificial' earth satellites.

* Substance of an address delivered at the U.S. National Telemetering Conference, Albuquerque, New Mexico, on May 21.

International Co-operation

The use of radio exploring and measuring techniques for investigating the Earth and the Universe around it must inevitably be developed on an international basis; and most of what I shall refer to relates to the activities of various scientific organizations whose co-operation is essential to the successful realization of research in these fields.

I am honoured to be the president for the present term of the International Scientific Radio Union (URSI), which has collaborated with its sister bodies, the International Astronomical Union (IAU), the International Geodetic and Geophysical Union (UGGI), the International Union of Pure and Applied Physics (IUPAP), and more recently the International Committee on Space Research (COSPAR), in the exploration by the aid of radio waves of the physics of our Earth, its atmosphere and all the space beyond. I may direct attention to the fact that the URSI will be celebrating the fiftieth anniversary of its formation at the General Assembly to be held in Tokyo

next September. Nevertheless, and in spite of this seeming age, URSI still maintains a position in the forefront of international research, in which radio is so essential for the acquisition and communication of scientific information.

Exploration of the Troposphere

In the British Standard's *Glossary of Terms used in Telecommunication and Electronics* (No. 204, 1960)*, 'radio telemetry' (or radio telemetering) is defined as: "Automatic communication by radio intended to indicate or record a measurable quantity at a distance".

Thus telemetry is essentially the science and practice of making measurements of physical quantities at a point remote from the observer, and then communicating the results by radio to this observer. In accordance with this definition, one of the earliest applications of telemetry was in meteorology, as a means of observing directly conditions in the Earth's atmosphere. A small package, containing a barometer, thermometer and hygrometer together with a radio transmitter and power supply, is carried aloft by a hydrogen-filled balloon. At pre-determined intervals, which can be set by a clock or a wind-vane mechanism, the indications of the three meteorological instruments are used to modulate, at different audio-frequencies, the higher frequency of the radio transmitter. Thus as the balloon ascends, and drifts with the wind, the signals received at the ground are used to record automatically the pressure, temperature and humidity of the air through which the instruments are being carried. In the more advanced techniques developed in the United States, the information from the temperature and humidity elements is combined in such a way that the refractive index of the air is calculated and telemetered to the ground station. Furthermore, by attaching a suitable reflecting 'target' to the balloon, a radar station on the ground is used to plot the horizontal projection of the balloon's position as it is carried along with the wind. From a recording of the pressure, corrected for the temperature as may be necessary, the height of the instruments is deduced; so that a complete knowledge of the vertical structure of the atmosphere is obtained at the ground station, including the two components, direction and speed, of the wind velocity.

The technique of sounding the troposphere, or lower atmosphere up to heights of some 30 km (100,000 ft.), is now a routine operation in many countries; and it provides a major contribution to the meteorological services of the world. Since much of the weather in the United Kingdom and Western Europe comes from a westerly direction, Europeans are very conscious and grateful for the advance information they obtain from ground stations on the American continent, and also from the mutually operated weather-ships in the Atlantic, which make full use of the radio-sounding technique.

Radio transmission and measurement techniques have, however, provided much greater facilities to the meteorologist than that of merely recording the basic parameters of an atmosphere. For example, the physical mechanism by which raindrops form and fall to the ground has been the subject of discussion among meteorologists for a very long time; but in the past decade or so, the centimetre wave radar installation has provided a powerful new tool for the meteorologist. Examination of the echoes scattered back to the observer from raindrops, or from snow and ice particles, has thrown considerable new light on the fundamental physical processes involved, as well as providing advance information on the onset of storms. Associated with this has been the application of radio reception to the investigation and movement of sources of atmospherics, which themselves provide supplementary advance information on weather conditions. Furthermore, during a thunderstorm the actual lightning stroke occurs down a column of ionized air, which as an electrical conductor can give rise to strong radar echoes, even when the actual precipitation of rain is too weak to produce a detectable response. In this way, lightning occurring either from cloud to ground or from cloud to cloud can be detected and followed out to ranges up to 100 km (70 miles) or more; and this again forms a valuable aid to the meteorologist.

I would like now to refer to the subject of 'angels', those mysterious meteorological echoes which have puzzled the investigator for about a quarter of a century. It is at times thought that these echoes are reflexions from areas of sharp change in gradient of the meteorological conditions in the atmosphere, such as the upper or lower boundary of a cumulus cloud or the region of a temperature inversion layer. But it seems to be the experience of many investigators that the gradients required by theory exceed measured or reasonable values by one or two orders of magnitude. However, some of this discrepancy may in the past have been due to the limitations of the measuring technique.

The direct measurement of the refractive index of the air with meteorological type instruments has already been mentioned. In the past decade or so, the technique of micro-wave refractometry has been developed in several countries. Here the natural frequency of a cavity resonator exposed to the atmosphere is compared with that of a sealed and, if necessary, evacuated resonator; and the refractive index determined from the difference in frequencies. The micro-wave refractometer, as the resonator combination is termed, is sufficiently small and light to be carried in a suitable position outside a small aircraft. Various types of this instrument have been developed; and one of these is in the form of an expendable radio refractometer, which can be dropped from a suitable altitude. A self-contained oscillator radiates at the natural frequency of the cavity; and the variations of frequency are recorded at the ground as a direct and continuous measure of the refractive index of the sample of air in the cavity. In this way, a quick and direct record is obtained of the vertical gradient of the refractive index of the air through which the resonator descended.

While much of this research work has been conducted with the object of assisting the meteorologist to gain a better knowledge of the physical characteristics of the atmosphere, it has concurrently been most useful to the radio scientist endeavouring to understand and turn to practical account the transmission of very short waves through this, un-ionized, portion of our atmosphere.

Exploration of the Ionosphere

In the presence of world-wide radio communications on the scale practised to-day it is perhaps not easy for the present generation to realize that it is not much more than forty years ago that the existence of the ionosphere was subject to experimental verification in both Great Britain and the United States. Two methods were used in these early experiments to demonstrate the existence of a reflecting layer of ionized air. The first of these used a frequency sweep technique at the transmitter, and the recording of interference fringes at the receiver where both the ground and sky waves were received. This method has since found another useful application in aircraft altimeters.

The second method consisted in sending out small pulses of radio waves and measuring the time taken for such pulses to travel up to the reflecting region and back again. Knowing the speed with which the waves travel, the distance of the reflecting region could be calculated from the observed time-interval. This method provided the basis for the development of radar about a quarter of a century ago. But even before such applied development started, the pulse-echo technique had found widespread use in the scientific exploration of the ionosphere in various parts of the world.

* British Standard 204, 1960, published by the British Standards Institution, London.

Systematic measurements made by this method, soon indicated that the hypothesis of a single ionized layer was insufficient to explain all the observed facts. The original experiments were made with medium-frequency waves: by using higher frequencies it was found that the waves could penetrate the lower, or E, layer and were reflected from an upper ionized, F, region, which itself was found to be complex, and on occasions it was divided into two parts (F_1 and F_2). Later research has shown that at certain times the short (or high-frequency) waves are reflected from intense clouds of ionization in the first or E layer; and also that very long waves (of low frequency) are reflected from a lower, D, region of smaller conductivity. In this way, we have come to realize that the ionosphere is that portion of the atmosphere situated 50–250 miles (80–400 km) above the Earth, with some highly ionized and so electrically conducting layers at heights of the order of 50 miles (80 km) for the D region, 75 miles (120 km) for the E, 150 miles (250 km) for F_1 and 250 miles (400 km) for the F_2 regions. The actual values of these heights vary markedly, as also do their electrical or reflecting properties, from day to night, and for different parts of the Earth.

World-wide radio communications depend directly on the successive reflexion of radio waves between the Earth and the ionosphere, in order that the circuits may overcome the curvature of the Earth. The design and operation of these circuits therefore involve a knowledge of the conditions in the ionosphere in various positions all around the world: and this, in turn, involves a measure of international co-operation in investigating the characteristics of the ionosphere over different countries. A considerable impetus to this type of international research was given thirty years ago, during the International Polar Year of 1932–33, when a successful exploration of conditions in the ionosphere at high latitude was carried out. The results of this work disclosed the close relationship between magnetic storms and abnormal conditions in the ionosphere leading to difficulties in radio communications, and on occasions to radio black-outs.

In the following quarter of a century, many countries established ionospheric observatories for the regular recording of the characteristics—the height of and the density of ionization of the reflecting regions—in different parts of the world. Under the auspices of the International Scientific Radio Union (URSI), the results of such observations were co-ordinated and used in the preparation of world-wide charts of predicted ionospheric conditions, which were applied by national administrations in the planning of their communication services. By systematically comparing the actual performance of these services with the forecast conditions, the knowledge of the conditions in the upper atmosphere was steadily increased, and the accuracy of the predictions correspondingly improved. It soon became apparent, as was to be expected, that, since the electrification of the ionosphere was dependent on ultra-violet radiation from the Sun, the characteristics of the ionosphere varied with solar activity in accordance with the 11-year cycle already established from astronomical observations. Now, the International Polar Year of 1932–33 was associated with a relatively quiet period of solar activity; and having in mind the rapid rate at which scientific research in radio was advancing, another international co-operative effort was conducted in 1957–58, at which time solar activity would be a maximum. In the event, this turned out to be the most intense period of such solar activity ever recorded since optical observations were first made some 200 years ago. Because of the greater scope of the physical measurements involved, and because the area of investigation was over the world as a whole and not confined to the polar regions, this period was designated the International Geophysical Year, which actually extended from July 1, 1957, to December 31, 1958.

The International Geophysical Year 1957–58

During the foregoing period, scientists of some 66 nations worked at more than 4,000 observatories throughout the world on a co-operative programme concerned with the physical properties of the Earth and its atmosphere, and with the related solar and terrestrial phenomena. In order to ensure the approximate simultaneity of the measurements, a calendar of observation days was drawn up in advance and, in this, provision was made for the declaration of Special World Intervals (SWI) when the state of the Sun indicated the likelihood of a geophysical disturbance which might affect, for example, the ionosphere and the Earth's magnetic field. For this purpose an international network of radio and line communications was used to alert all participating observers and warn them that a SWI might, subject to confirmation, begin 16 h later. During the International Geophysical Year, 44 such alerts were distributed; and of these, 22 culminated in a Special World Interval observing period, during 17 of which, major solar and terrestrial disturbances occurred. In addition, there were 6 severe and 33 mild disturbances for which no previous warning or alert had been issued.

Provision was also made in advance for the setting up of a number of World Data Centres. Two of these, in the United States and the U.S.S.R., collected the observational data relating to all types of measurements at the large number of observatories involved. Two others, in Britain and Japan, confined their collections to radio and associated measurements on the characteristics of the ionosphere, on atmospheric disturbances and on aurora.

The primary aim of the meteorological programme for the International Geophysical Year was to obtain a more nearly complete global picture of the mechanism of the general circulation in the atmosphere. To this end special stations were established in the polar regions, equatorial areas and on oceanic islands to supplement observations made daily throughout the extensive network of permanent meteorological observatories. Measurements made with radio sounding balloons were extended to greater heights up to some 50 miles (30 km) where practicable, thus extending their scope into the lower regions of the ionosphere. More frequent soundings were made on the Special World Days; and considerably increased observational facilities were provided on the Antarctic continent. As a result, the meteorologist has been able, for the first time, to construct charts showing broad circulation patterns at various atmospheric levels above the Antarctic.

Meteorologists also collaborated with radio scientists in investigating the nature and motions of thunderstorms, which make themselves evident by the emission of radio waves from lightning flashes. Among the main objectives of the International Geophysical Year noise programme were measurements of the average power received at radio frequencies from lightning flashes, and a detailed investigation of the waveform of the radiation over a wide range of frequencies. As a result of co-operative work of this type, charts are now available from which an estimate can be made of the level of interference to communications due to atmospheric noise likely to be experienced in any part of the world at any time or season and on any radio frequency. Such information is invaluable to both national and international authorities planning global communications networks, including those used for broadcasting and navigational aids.

One of the most useful results of the extensive and world-wide investigation of the ionosphere during and since the International Geophysical Year is that charts have become available whereby the communicator, as the user of radio communications is sometimes termed, can plan, many months and even years ahead, the frequencies most favourable for his use over various circuits at all times and seasons and in all parts of the world. Such

charts normally indicate the maximum frequencies usable on communication circuits; and they have been based on the assumption that the electron density in the upper, or F_2, region of the ionosphere increases with height according to a parabolic law. The calculation of these ionization densities by manual methods is an arduous operation; but, during the International Geophysical Year, first in the United Kingdom and later in other countries, digital computers have been programmed to calculate these distributions of electron density on a routine basis. As a result, it has been found that these distributions are often far from parabolic in form: and the practical conclusions reached are that, while the maximum usable frequencies obtained from the charts are not seriously affected by the shape of the layer, it would appear to be desirable to use aerial systems which project the radiation at a greater angle of elevation than has hitherto been considered the most appropriate.

The normal methods of sounding the ionosphere take little or no account of the fact that the reflecting layers are not at rest, but appear to be moving with horizontal velocities which vary with the height of reflexion. Special techniques have, however, been developed to measure the horizontal movements, or drifts; and some interesting results were obtained during the International Geophysical Year both in near-tropical regions and in the Antarctic. For example, at Ibadan, in Nigeria, it was found that the drifts of ionization were subject to a diurnal variation, the prevailing directions being to the west by day and to the east by night at all seasons. But these drifts are subject to a long-term change over the solar cycle. Now at Halley Bay, in the Antarctic, new and most interesting results were obtained. Among these was the somewhat unexpected observation that, although the Sun did not rise above the horizon as seen from the ionosphere for many weeks during the winter, the noon critical frequency or density of ionization was greater in midwinter than in midsummer, when the Sun did not set even during the 'night'. It is thus to be concluded that the conditions in the reflecting layers were determined by movements of ionization and not by direct solar influences.

These direct measurements of ionospheric conditions in the Antarctic were supplemented by detailed observations of the Earth's magnetic field and of the incidence of meteors and auroral activity. The systematic reduction of the great mass of these observations has continued over the past few years and several volumes of the results are in course of publication. As a result, our knowledge of the physical conditions both at the ground and in the atmosphere above the Antarctic continent has been considerably enhanced by this international co-operative enterprise.

The general operation of the programme of the International Geophysical Year and the increase in our knowledge already obtained from the results thereof are considered to have been so successful and rewarding that it has been decided to repeat this scientific investigation during the full calendar years 1964–65. During this period the activity of the Sun will pass through its minimum phase in contrast with the very high maximum activity which prevailed during the International Geophysical Year. The forthcoming two-year period (1964–65) is denoted as the International Quiet Sun Year (IQSY).

Rockets and Satellites for Geophysical Research

For some years before the International Geophysical Year, rockets carrying scientific instruments were used for research purposes to investigate the phenomena and characteristics of the upper atmosphere by direct measurement in a manner which ground-based experiments were unable to provide. Radio transmission was used to communicate to the ground station the measurements recorded by the instruments carried in the rocket. The technique may be regarded as an extension of that used in the radio sounding balloon which was developed by the meteorologist many years before. As an indication of the great progress made in this field, it was reported as recently as April 1963 that a *Skylight* rocket sponsored by the British Meteorological Office had reached a height of 145 miles at Woomera in Australia, as part of a programme of direct research into the physical properties of the upper atmosphere.

Reverting to the International Geophysical Year programme, however, the first successful application of artificial Earth satellites carrying scientific instruments for investigating the space around us occurred in October and November 1957, when the U.S.S.R. launched the satellites known popularly as *Sputniks I* and *II*. These were followed in January, 1958, by the American satellite *Explorer I*; and many others of various types and instrumentation have followed in the succeeding five or six years. The immediate success of the early launchings was impressive, and they constituted the most spectacular results arising directly from the operation of the International Geophysical Year. These satellites were equipped with instruments for the measurement of the properties of the atmosphere, the electron density of the ionosphere and the intensity of cosmic and solar radiation in outer space. The output of these instruments is in electrical form, and is either transmitted directly by radio to the ground observing stations, or is recorded on magnetic tape and sent later on receipt of a command signal from a radio station on the Earth. Some of the telemetry systems are relatively simple, but others are more complex and use up to 48 frequency channels. While the early transmissions were on the relatively low frequency of 20 Mc/s, and others on a frequency of 108 Mc/s, it is now customary to use the band 136–137 Mc/s, which has been assigned by the International Telecommunication Union for space research purposes. In one of the typical telemetry systems used, the modulation signals consist of 16 bursts of tone, the information being carried by the tone frequency of 5–12 kc/s, the duration of the bursts and the intervals between them, giving 48 channels in all. The power of transmitters in the early satellites varied from 10 to 100 mW for continuous operation, while for intermittent operation on command, several watts may be available.

Apart from the need to extract the observational information from the satellite, radio transmission is used to track it and supplement the positional information which may be obtained visually under clear sky conditions. Radio interferometers and tracking equipment have been installed in a number of countries to give round-the-world coverage by international co-operation. Additional information provided by the radio signals includes a determination of successive orbit periods, from a knowledge of which information is obtained as to the shape of the Earth, variations of gravity at different altitudes and the drag of the rare atmosphere at the orbit-levels.

While research on cosmic rays at high altitudes was in progress before the International Geophysical Year by means of balloons and rockets, the scope of the work has been considerably extended by the use of satellites carrying instruments for measuring the intensity and the energy distribution of the radiation. Also the discovery by van Allen and his colleagues of the high-intensity radiation belts which surround the Earth is one of the outstanding results of the International Geophysical Year. Later observations have indicated the existence of two belts of high-intensity radiation around the geomagnetic equator: the first is at a height of about 10,000 km, while the second is at approximately 22,000 km. These belts consist of charged particles the density of which recorded on a Geiger counter varies over a range of 10,000 to 1 under different conditions. The examination of these particles trapped in the Earth's magnetic field is providing a major contribution to our knowledge of the characteristics of the outermost portions of our atmo-

sphere, and the influence which the Sun's radiation has on these characteristics.

This subject has now become a very wide and active field of scientific research.

Top-side Exploration of the Ionosphere

So far I have referred to the progress made in the investigation of the characteristics of the ionosphere by radio wave echo-sounding technique conducted from ground stations. In this work it has been known for a long time that there is an upper limit to the frequency of the waves which are reflected from the higher ionized regions; and higher frequency or shorter waves penetrate these regions and travel on into outer space. We have, therefore, in the past been prevented from learning anything about the state of ionization in the atmosphere above the highest, or F_2, region. But the successful launching of artificial Earth satellites and the development of telemetry associated therewith has removed this limitation. By transferring the whole of our ionospheric recording instruments, including both the transmitter and receiver, to a satellite vehicle, we now have the facility of doing the ionospheric sounding from above the F_2 region and, by telemetry, the recorded results of the soundings can be communicated to the scientists in their ground laboratories.

This has been achieved by the collaboration of the U.S. National Aeronautics and Space Administration with the Canadian Defence Research Board and National Research Council. The satellite, termed scientifically 1962 $\beta\alpha 1$ but more colloquially known by the title *Alouette*, was launched on September 29, 1962, by a *Thor Agena B* rocket from the Pacific Missile Range; and it has been an outstanding success.

The *Alouette* satellite contains, in addition to the sounder, apparatus for counting cosmic ray particles, for observing the very-low-frequency radio spectrum and for monitoring the engineering performance. The sounder itself comprises a self-contained transmitter and receiver, both fully transistorized: the frequency is swept over a range of 0·45–11·8 Mc/s at a rate of 1 Mc/s per sec; and with a pulse-width of 100 μsec and repetition frequency of 67 c/s, the peak pulse power is 100 W. In addition, the satellite carries a beacon transmitter, and two telemetry transmitters operating in frequency channels within the 136–137 Mc/s band. The orbital parameters of *Alouette*, as calculated by the National Aeronautics and Space Administration Computation Centre in October 1962, shows that it travels around the Earth in an elliptical orbit with an eccentricity of 0·002 35, a period of 105·4 min and at heights of about 996 and 1,031 km (622 and 644 miles), at perigee and apogee respectively.

The general form of the ionograms obtained from this sounder are similar to those recorded at ionospheric observatories at the ground. At the lowest frequencies the ionized plasma is too dense for penetration; but as the frequency increases, pulses received from below the satellite are observed and show that the waves are reflected upwards from the top-side of the ionosphere, and above the level of maximum ionization of the F_2 region as observed from the ground. A typical top-side ionogram shows that the apparent height of reflexion falls rapidly from the satellite height at 2·0 Mc/s and then, as the frequency increases, the waves penetrate the ionosphere at 8·1 Mc/s, and are afterwards reflected from the ground. Thus the technique provides the means for exploring the ionosphere at all heights from ground-level to more than 1,000 km (more than 625 miles), by combining the *Alouette* records with those normally obtained at some of the ground observatories over which the satellite passes. In addition to an investigation of the preliminary results obtained by the Canadian scientists, two other investigations have been proceeding in the United Kingdom and the United States respectively. In the former, telemetry signals have been recorded from the satellite as it passes over the Radio Research Station, near Slough in England, and over its associated stations in Singapore and the Falkland Islands. In the United States, staff of the Central Radio Propagation Laboratory at Boulder, Colorado, have already examined some of the data recorded during 27 passes of the satellite over the telemetry station of the National Aeronautics and Space Administration at Blossom Point, Maryland. It is already clear that, by international collaboration in the field of geophysical research, the new techniques of radio and telemetry have opened up extensive new vistas in our exploration and understanding of the physical properties of our atmosphere, and the manner in which this is influenced by radiation from the Sun and outer space.

Conclusion

Apart from the application of instrumented satellites to direct scientific research, the recent successful launching into orbit of the *Telstar* and *Relay* satellites has similarly opened up a vast new field of inter-continental communications including the exchange of sound and television programmes, the possibilities of which have already been demonstrated. Truly it may be said that telemetry is a field of electrical or electronic engineering which is destined to play a most important part in bringing the nations of the world into closer and more direct communication, and at the same time provide them with a more detailed knowledge and understanding of the universe around our own planet, the Earth.

THE SHIRLEY INSTITUTE

By Dr. DOUGLAS W. HILL
Director of Research

ON May 21, H.R.H. Princess Margaret, Countess of Snowdon, formally opened the new Chemistry and Finishing Building of the Cotton Silk and Man-made Fibres Research Association at Didsbury, Manchester. Better known as the Shirley Institute, the Association is the second largest of the present fifty-two research associations in Great Britain. It was incorporated in 1919 and moved to its present site on the southern outskirts of Manchester in 1922. The site embraces a total area of 21½ acres and the accommodation now comprises four main groups of buildings providing some 221,000 sq. ft. of laboratories, experimental workrooms, offices, library, etc.

Buildings

The Towers (26,000 sq. ft.): The original, and still central, building is the original residence existing on the estate at the time of its purchase (Fig. 1). It is a large, three-storey, typically Victorian building erected in 1865 and now houses the library and Information Department, in which is maintained what is claimed to be the finest collection in the world of books on textile subjects. It contains about 20,000 books and pamphlets, increasing by about 600 every year; in addition more than 300 technical and scientific journals are taken annually.

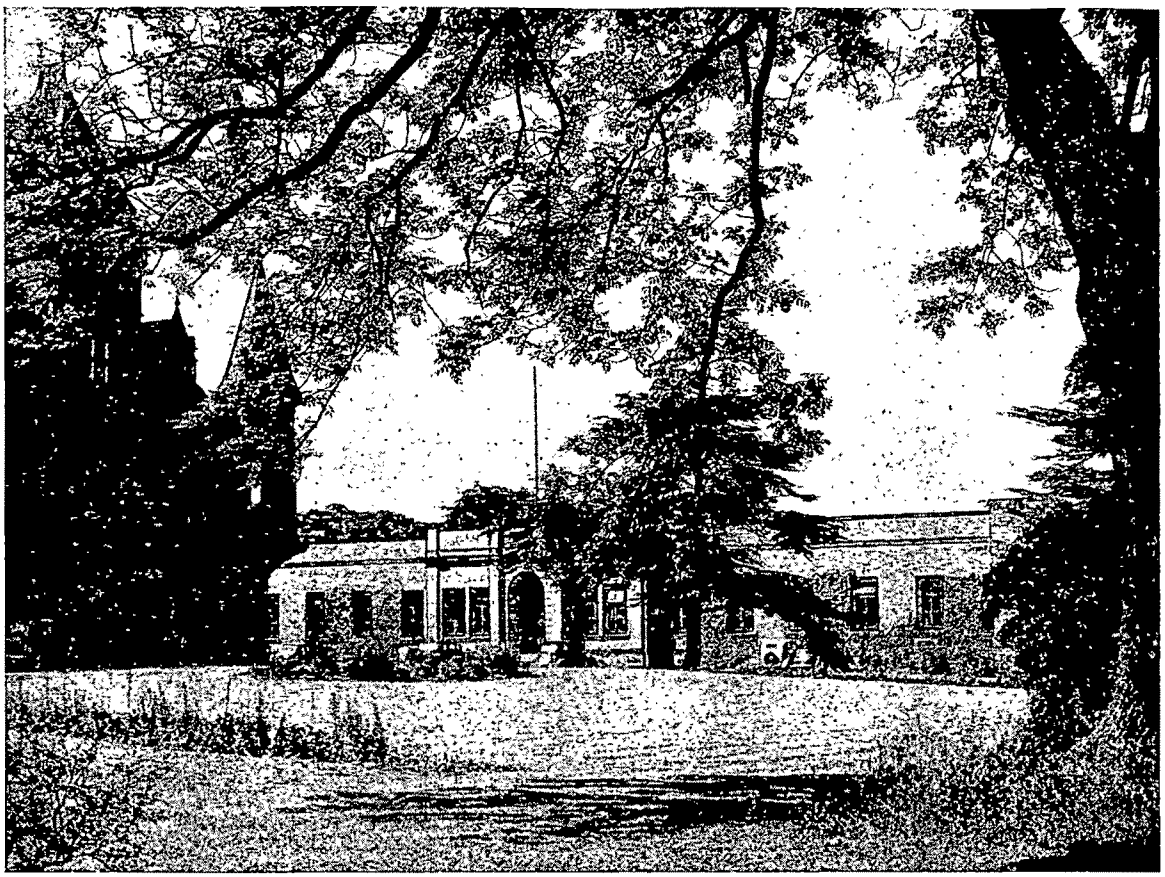

Fig. 1. The Shirley Institute. The Towers and Old Laboratories

Old Laboratories (100,000 sq. ft.) : The earliest part of these buildings, a laboratory block of thirty rooms, was built in 1922 and was formally opened on March 28 of that year by H.M. the late King George VI (then H.R.H. the Duke of York) (Fig. 1). Between 1922 and 1949, six additions were made to this original block, more than one-half in 1936 or afterwards. The buildings have constantly been modernized and re-equipped to bring them in line with present-day standards. They now accommodate the Spinning, Weaving, Finishing, Chemistry, Fibre Structure, and Engineering Departments, and include, in addition to the laboratories, a cardroom, spinning and doubling rooms, a weaving shed and a large engineering shop.

Physics and Administration Building (38,000 sq. ft.): This block, which was erected in 1952, comprises three two-storey wings (Fig. 2). One wing houses the central administration of the organization, together with offices for the Liaison Department. The other two wings are completely air-conditioned for temperature and humidity and provide accommodation for the Physics and Testing Department, and, temporarily, the Silk Department and Drawing Office.

New Chemistry and Finishing Building (57,000 sq. ft.): This building has just been completed (Fig. 3) and is the one recently opened by Her Royal Highness. It has been designed to accommodate staff and machines engaged on research into the finishing of cloth both in the laboratory and in processing rooms simulating works' conditions, and represents the final stage in the amalgamation of the former British Cotton Industry Research Association and the British Rayon Research Association which was effected in April 1961. Of the total area of 57,000 sq. ft., laboratories and offices occupy 32,000 sq. ft. on two floors, and a single-storey machine room somewhat similar to a dyehouse occupies the remaining 25,000 sq. ft. Separate sections at each end of the machine room accommodate pilot size plant for small-scale experimental work. The workroom area is separated from the laboratory block by a sound-absorbing buffer area mainly devoted to storage and service rooms.

The laboratories have been designed to allow for the maximum flexibility in any future desirable re-arrangement. Services to the machine room are generously disposed in underground ducts terminating at regular intervals in grouped assemblies, thus making for easy access and connexion to new machines with a minimum of disturbance to experiments in progress. In the laboratories the services are disposed in a co-ordinated modular arrangement in vertical ducts which, together with a system of hollow tubes resting on the structural floor, enables any service to be run conveniently to any point. The services provided include steam at various pressures, a central vacuum system, two pressures of compressed air, gas, electricity, hot and cold water. A feature of the services is that the whole of the Institute's cold water system is now filtered. The plant and storage tanks for the new system are housed in the basement of the new laboratory. The main heat source for the building is supplied by steam from a central boiler house where new oil-fired boilers have been installed.

The opportunity has been taken to lay out the grounds of the Institute afresh and, of course, to instal new and up-to-date machinery and equipment.

The new building and the associated work have cost about £450,000 while a further £50,000 has been spent on specially purchased equipment.

Chemical and finishing researches have, of course, been in progress at the Institute for many years but the opening of the new building will mean that this work can now be extended and carried out in ideal conditions.

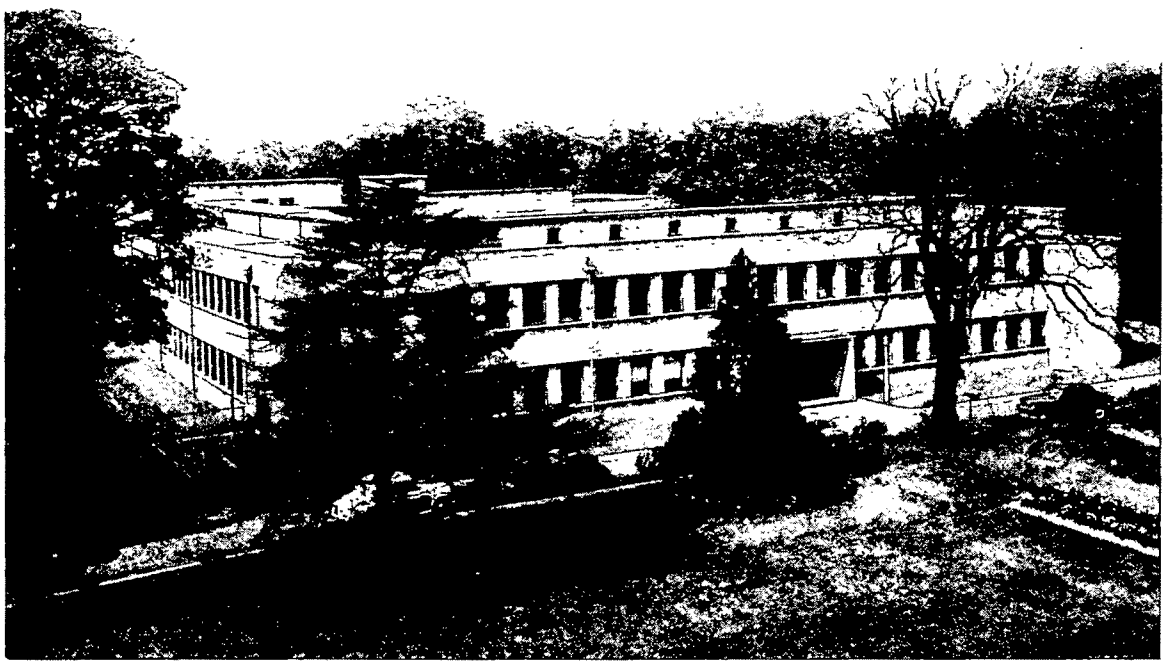

Fig. 2. Physics and Administration Building

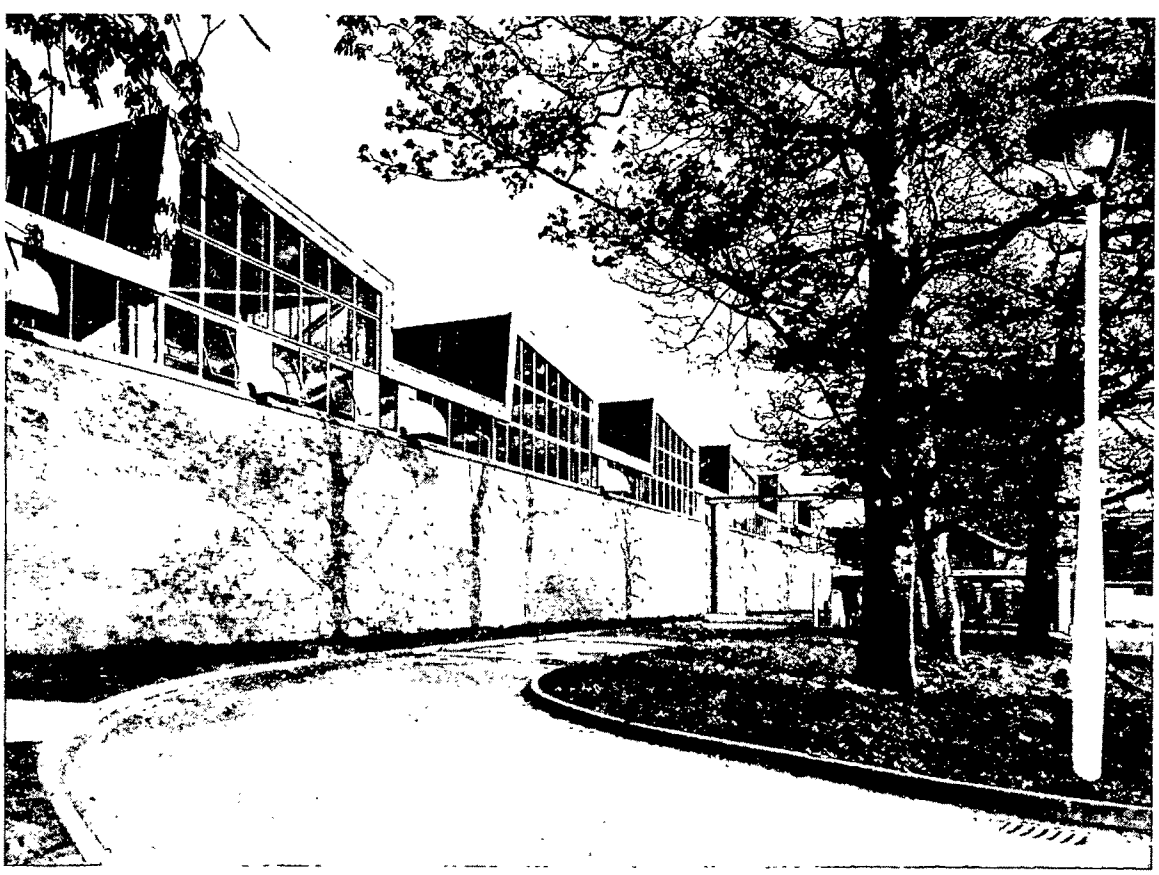

Fig. 3. Western aspect of the new Chemistry and Finishing Building

Work and Objectives of the Institute

As its formal name implies, the Institute is primarily a research organization. The founders expressed its primary aim in the words "Our task is not to make handicraftsmen, but to imbue the whole industry from top to bottom with the spirit of science; not to survey existing fields of knowledge but to break new fields and map out territories yet unknown". It is undoubtedly by adherence to this policy that the Institute has achieved its steady growth to maturity and to world-wide recognition. Starting with an annual expenditure of £4,000 in 1920, it increased this to £51,000 in 1929, to £93,000 in 1939, to £215,000 in 1949, and in the last financial year to almost £650,000. All subsequent experience has amply confirmed the wisdom of the original decision, because fundamental work is the basis of future applied research. In this respect the knowledge provided by fundamental research is the capital invested in the business of providing technological assistance.

In due course, the Institute was able to turn its attention to applied research, and since that time fundamental and applied research have progressed side by side, one feeding progressive ideas to the other and in return receiving fresh basic problems thrown up by their application.

It is difficult, as everyone knows, to draw a sharp line between fundamental and applied research, and equally so between applied research and development. It is, however, not enough to carry out fundamental research, or even to show how it may be applied to existing practices. It is often necessary to develop the new practices to the point of industrial exploitation, which often implies the production of new machines, instruments or equipment. Shortly after the Second World War, therefore, a separate Engineering Department was organized complete with drawing office, instrument section and machine shop. This Department can design and produce, in collaboration with the laboratories, any new prototype machines needed for full exploitation of the research ideas.

With this background of basic research, applied research and development, the Institute is able to assist the industry in a major way to solve its day-to-day problems. The use that the industry makes of this kind of service has increased enormously over the years, both in absolute amount and as a proportion of the resources available. The maintenance of an adequate amount of research as distinct from service work is a problem that faces all research organizations, which are always in danger of becoming the victims of their own research, since each successful investigation creates the need for further service work to ensure its successful application in industry. There is therefore a tendency for service work to increase continuously with disastrous consequences for the amount of research work that can be carried out.

At the present time about 35 per cent of the Institute's resources is utilized in service work to the industry, approximately the same amount in applied research and development, and about 30 per cent in fundamental research. Experience suggests that it would be unwise to permit the fundamental research to fall below this level and that to do so would destroy the character of the organization.

Finally the Institute has grown from a local industrial research organization to a great national and even international institution. Of the twelve thousand or more technical contacts it has each year some three thousand are with organizations not in membership of the Association. These include most of the Government departments, universities and colleges, trade associations, Trade Unions, and industrial concerns outside the textile industry. Many of these arise from the Institute's position as a leading authority on certain fields of science and technology as well as from the need of laymen to have a source of expert advice on textile problems with which they may be confronted.

With the completion of the most recent new building, the course embarked on by the founders may be said to have been completed. The Institute is now well equipped in every field of its activities. It is fitting, therefore, that in opening the new building H.R.H. Princess Margaret should also have formally completed on Tuesday, May 21, what her father H.M. the late King George VI formally initiated on another Tuesday forty-one years earlier.

ABERDEEN MEETING OF THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

By Dr. R. B. STRATHDEE, O.B.E.
Department of Chemistry, Aberdeen

WHEN the British Association for the Advancement of Science was founded in 1831 Aberdeen had two universities, both degree-granting, King's College, founded in 1494, and Marischal College, founded in 1593. Among the scientists who at that time expressed concern at the unsatisfactory position of science in the country and who were instrumental in forming the Association was John Herschel, who was appointed Rector of King's College in 1842. The Association did not visit Aberdeen until 1859. In the previous year a company had been formed in the city to take over what was then known as the Assembly Rooms, a large building in Union Street erected in 1820, the architect being a distinguished Aberdonian, Archibald Simpson. The new Music Hall Company reconstructed the interior of the building, one of the main changes being the conversion of a commodious dining-room into a hall capable of seating a very large gathering. The first public meeting held in this Music Hall was on the evening of September 14, 1859, when H.R.H. Prince Albert delivered his address, as president of the British Association, to an audience of 2,500, and in the same hall Sir Eric Ashby will also this year address the Association (see *Nature*, 195, 856; 1962). Her Majesty in 1859 graciously entertained to lunch at Balmoral Castle the members of the General Committee and the distinguished foreign visitors present. The British Association visited the city again in 1885 when Sir Lyon Playfair was president and in 1934 when Sir James Jeans occupied the chair. Annual meetings have, on occasion, been used for the announcement of outstanding scientific discoveries, and on the latter occasion the story of vitamin C (ascorbic acid), its isolation, structure and synthesis, was revealed to the chemistry section by Profs. A. Harden, A. Szent-Györgyi, E. L. Hirst and W. N. Haworth.

Aberdeen, the principal town of the maritime county of the same name, has been a Royal Burgh for more than eight centuries and to-day ranks as the third city of Scotland. Throughout the years Aberdeen has sought to develop its natural resources, and the area boasts a rigorous modern agriculture and industry. Situated on the coast between the Rivers Dee and Don, with a splendid hinterland of field and forest, mountain and moor, its attractions as a tourist and holiday centre have long been recognized. The cultural life of the city had its roots in the

ancient church and to-day the city is ideally placed to act as host for the 1963 meeting of the British Association, with its University and its Robert Gordon's Technical College, where the reception centre and administrative offices will be situated. In addition, Aberdeen is the home of many research institutes, namely, the Rowett Institute (for research in animal nutrition), the Macaulay Institute for Soil Research, the Marine Laboratory and the Torry Research Station (Department of Scientific and Industrial Research).

With such potentialities, an interesting and varied programme of excursions, both general and sectional, has been arranged; members will have an opportunity to visit industrial works, the research institutes, places of interest within the city and such well-known areas as Deeside, Donside, Speyside and the north-east coast. The dates of the meeting coincide with the Edinburgh International and the Pitlochry Festivals, and the various Highland Games and Gatherings are also held around this period so that members can include such functions if they wish to extend their visit to the north. Two longer excursions (limited in numbers attending) have been arranged for a period just before and after the meeting; these will be based at Tarradale House, Muir of Ord, Ross-shire, the University Field Centre in the Black Isle, and will be led by geographers from the University.

One of the first of the local committees to function in the arrangements for the Aberdeen meeting was a small committee under Prof. A. C. O'Dell, which was set up by the University to compile and publish a survey, largely scientific, of Aberdeen and district. This small group was later enlarged to become the Publications Committee of the local organization. Authors were chosen for their particular knowledge, and the volume, which will be published at the opening of the meeting under the title *The North-East of Scotland*, will form a valuable contribution to the literature of the area. The sections of the book cover natural history, regional settlement, agriculture, forestry and fisheries, industries, commerce and trade, population, education and research with an account of scientists of the North East. A copy of this publication will be presented to each member attending the Aberdeen meeting, and it is anticipated that a limited number of copies will be available for sale to libraries, etc., after the close of the meeting.

The president of the 1963 meeting is Sir Eric Ashby (see *Nature*, 195, 856 ; 1962), the eminent botanist and Master of Clare College, Cambridge. He will deliver his presidential address on the evening of Wednesday, August 28, on "Investment in Man", a subject which will provide an interesting sequel to Sir John Cockcroft's address last year at Manchester on "Investment in Science". Preceding the address, the Vice-Chancellor, Dr. E. M. Wright, on behalf of the University of Aberdeen, will confer the honorary degree of LL.D. on Sir George V. Allen (see *Nature*, 197, 128; 1963), who this year retires from office as secretary of the Association, on Sir Charles Morris, vice-chancellor of the University of Leeds and president of Section L (Education), and on Prof. J. Monteath Robertson, Gardiner professor of chemistry, University of Glasgow, and president of Section B (Chemistry).

Two evening discourses will be given, one by Prof. C. F. Carter on "Problems of Economic Growth" and the other by Prof. R. V. Jones (subject to be announced later). The presidential addresses of the various sections cover a wide range of topics from "High-Voltage Insulation" (Section A) to "Urban Planning and Location of Industry" (Section X). It is one of the purposes of these annual meetings "to disseminate scientific knowledge among the lay public" and the non-scientist should find much to interest him not merely among the presidential utterances but among the various papers, etc., which make up the sectional programmes. Of much interest to all Scots men and women must be the joint sessions of Sections E (Geography), F (Economics), K (Botany), K* (Forestry) and M (Agriculture), covering two whole days, to discuss "Land Use in the Scottish Uplands". These meetings will be 'chaired' by Lord Lovat, Prof. J. R. Matthews, emeritus professor of botany, University of Aberdeen, Dr. R. F. Hunter of the Hill Farming Research Organization, Edinburgh, and Prof. J. R. Raeburn, Strathcona-Fordyce professor of agriculture, University of Aberdeen. Speakers of many interests will take part including Sir Robert Urquhart, chairman of the Crofters' Commission.

There will be, in various centres, a number of exhibitions: in two of the rooms adjoining the Music Hall there will be a display based on "Forestry and Forest Products" contributed by research institutions and industry, while in the neighbouring ballroom the Ordnance Survey will have on show maps focused on Scotland and on some of the topics under discussion at the meeting. In the Art Gallery there will be on view models and diagrams illustrating the theme "Cities and Universities of the Future". In Scotland to-day very considerable efforts are being made to change the physical appearance of the cities and this exhibition will reveal the lines along which the planners are thinking. Under the auspices of the Institute of Science Technologists there will be at Marischal College an exhibit of teaching aids and apparatus made by the technical staff of various university geology departments. Also in Marischal College (Wilson Room) there will be on display the magnificent St. Ninian's Treasures discovered by Prof. A. C. O'Dell and his party while excavating on that isle in 1958. In the University Library at King's College, there will be available for inspection a number of books, etc., of special and historical interest. "Teaching Machines and Programmed Texts" will be the subject of an exhibition in the College of Education, and in the Chemistry Department of the University will be a display of equipment illustrating the "History of the Microscope". The National Book League is to stage an exhibition of books in the Reception Centre; these will include, in addition to a general section, three subsidiary sections covering forestry, archæology and sociology.

In 1956, Aberdeen Town Council purchased a vacant church—a large Grecian structure, modelled on St. Pancras Church, London—with an imposing portico of four Ionic pillars, above which rises a clock tower. The interior of the building has now been reconstructed to provide on the upper floor an auditorium to seat 390, with dressing-rooms, etc., and on the ground-floor a library and lecture rooms. Now renamed the "Civic Arts and Adult Education Centre", this building will serve as a centre for the arts, drama, music, painting, etc., within the city and it will be used for the first time during the meeting of the British Association. Here the programmes of scientific films will be screened and these will include films from thirteen different countries. There will be two morning sessions for young people, free lunch-time and evening performances for the general public, and afternoon periods for members. In addition there will be a display of audio-visual equipment kindly provided by the Rank Organization.

One of the main functions of the British Association is to enable scientists not merely to meet one another but also to meet the men and women of the city and surrounding districts who are their hosts. To enable this purpose to be achieved, the City and the University are both giving receptions while, in addition, there will be a number of smaller functions and garden parties. It is perhaps invidious to single out any one of these, but one interesting function will be the performance of Haydn's "Creation", given by the Haddo House Choral Society on Sunday evening. A buffet supper will be served and members will have an opportunity to view the house and to walk through the grounds. Haddo House was designed for William, the second Earl of Aberdeen, by William Adam, father of the Adam brothers, in 1731; among its treasures are many fine portraits and some beautiful china. Major

David Gordon, grandson of the present Earl, has with his wife done much to foster a love of music in the north-east. For more than forty years students and graduates of the University have staged a theatre show during their Charities Week. When the British Association visited Aberdeen in 1934 they presented the pageant "Town and Gown" in honour of the visit, and this year, during the first week of the meeting, they are to stage a revue under the title "Element of Surprise".

Following the usual pattern of British Association meetings, a special programme has been arranged for young people. In the High School for Girls there will be a Science Fair, which will be opened on Thursday morning by the President. Here there will be on display exhibitions and experiments devised by the pupils of the secondary schools and colleges of Aberdeen and the neighbouring counties. Of the many items listed among the projects is one, by the Gordon Schools, Huntly, under the intriguing title of "There is more to Transistors than Cliff Richard". The opening ceremony will be followed later in the morning by a reception at which pupils and staff will have an opportunity to meet the President and Officers of the Association. Among the many other items arranged for the young people is a 'Brains Trust' when a panel of scientists will attempt to answer questions sent in by the pupils, and a full programme of lectures including the York Lecture by Sir Raymond Priestley, president of the Royal Geographical Society, on "Antarctic Exploration Yesterday and To-day". Sponsored by Section X there will be on Monday morning a series of talks, under the title "Science in the Sixth Form", given by seven secondary school pupils.

Aberdeen looks forward with interest and with pleasure to its fourth visit from the British Association, which the organizers hope will be even more successful than the three previous meetings.

OBITUARIES

Dr. Theodore von Kármán, For.Mem.R.S.

Theodore von Kármán was born in Budapest on May 11, 1881, son of Prof. Maurice von Kármán, a distinguished pedagogue and philosopher, and Helene Konn. After graduation in 1902 with highest honours as a mechanical engineer from the Budapest Royal Technical University, he spent the next four years in Hungary, teaching at the University and performing theoretical research on machine design problems for Ganz and Company.

The next six years were spent in study in London, Paris and Göttingen. His first direct contact with aeronautics occurred in Paris in 1907 when he saw Henri Farman fly a circular one-kilometre course. He settled for a time at the University of Göttingen to work with L. Prandtl, receiving a Ph.D. degree in 1908. His dissertation on the buckling strength of straight columns was the first of many major contributions. In this communication he set forth the double-modulus theory of column behaviour under loads which stress the column material beyond the elastic limit. Von Kármán continued as a teaching Fellow until 1912. During this period, stimulated by observing the difficulty of his colleague, Hiemenz, in obtaining symmetrical flow of water about a circular cylinder, he developed and published in three communications in 1911 and 1912 his well-known theory of the unsymmetrical vortex arrangement in the wake of a cylinder, commonly known as the Kármán vortex trail.

In 1912 von Kármán accepted an invitation to become professor of aeronautics and mechanics and director of the Aerodynamic Institute in the Technical University of Aachen. The Aachen period was one of rapid growth to eminence on the part of the man and the Institute. His interests turned largely toward fluid mechanics. Some of his most notable contributions dealt with the stability of laminar flow, the theory of turbulence, wing theory, pressure distribution on airship hulls and the Kármán integral relation for solving problems of boundary layer flow and skin friction.

During 1914–18 von Kármán served as director of research of the Austro-Hungarian Aviation Corps, returning to Aachen after the War.

In 1926 he visited the United States at the invitation of Dr. Robert Millikan of the California Institute of Technology and the Daniel Guggenheim Foundation for the Promotion of Aeronautics. Following a trip around the world, he arranged in 1928 to divide his time between Aachen and the California Institute of Technology. In 1930 he settled permanently in California as director of the Guggenheim Aeronautical Laboratory, becoming a U.S. citizen in 1936.

In the nineteen years of his association with the California Institute of Technology, von Kármán published some fifty communications in solid and fluid mechanics, alone and with his students. These included contributions to the theory of the buckling of spherical shells under external pressure, influence of curvature on the buckling characteristics of structures, the Kármán–Moore slender-body theory for bodies of revolution at supersonic speed, compressibility effects, supersonic aerodynamics, statistical theory of turbulence, and many others.

In 1939 von Kármán initiated rocket research at the Guggenheim Aeronautical Laboratory, especially for the development of assisted take-off rockets for airplanes. He directed the jet propulsion project, which later became the Jet Propulsion Laboratory. With a few friends he founded the Aerojet Engineering Corporation, the first American firm specifically engaged in rocket development in the United States.

Von Kármán took leave of absence in 1944 to organize a Scientific Advisory Group for General H. H. Arnold to analyse the use of science in warfare and to forecast the impact of new developments in rockets, jet propulsion, and supersonic flow on future air warfare. He retired from the California Institute of Technology in 1949, devoting much of his time to his duties as chairman of the U.S. Air Force Scientific Advisory Board, which succeeded the Scientific Advisory Group.

In 1951 von Kármán called a meeting of the directors of aeronautical research of the NATO countries, which resulted in the establishment of the NATO Advisory Group for Aeronautical Research and Development (AGARD) with headquarters in Paris. He was chairman of AGARD until his death.

Von Kármán was a leader in the organization of three additional agencies for international co-operation in science, the International Congress of Applied Mechanics, first held at Delft in 1924 following a preliminary meeting at Innsbruck, the International Congress of the Aeronautical Sciences, first held in Madrid in 1958, and the International Academy of Astronautics established within the International Aeronautical Federation.

Von Kármán was a foreign member of the Royal Society of London, a member of the U.S. National Academy of Sciences, Academie de Sciences de l'Institut de France, Academia Nazionale dei Lincei, Royal Academy of Sciences (Madrid), honorary Fellow of the Royal Aeronautical Society and honorary Fellow, honorary member or member of some additional 35 professional societies in 11 countries. He received more than 60 honorary degrees or special awards from institutions in 13 countries, including the U.S. Medal for Merit (1946),

John Fritz Medal (1948), Franklin Gold Medal (1948), Lord Kelvin Gold Medal (1950), Gold Medal, Royal Aeronautical Society (1952), Wright Brothers Memorial Trophy (1954), Daniel Guggenheim Gold Medal (1955), U.S. Medal of Freedom (1956), Ludwig Prandtl Ring Award of the Wissenschaftlische Gesellschaft für Luftfahrt (1956), Goddard Gold Medal (1960), U.S. National Science Medal (1963).

Theodore von Kármán died during a visit to Aachen on May 7, 1963, four days before his eighty-second birthday. His place as a leader in applied mechanics and aeronautical and astronautical science, and in international co-operation in science and engineering, will not soon be filled. HUGH L. DRYDEN

Dr. H. Baines

DR. HARRY BAINES, of Messrs. Kodak, Ltd., died suddenly on June 7.

Dr. Baines was an outstanding figure in the photographic world, where he was extremely popular not only for his wide scientific knowledge, but also for his very happy and genial personality.

Born in 1901 of Yorkshire parentage, Harry Baines spent his youth in Nottingham, where he studied chemistry under the late Prof. F. S. Kipping. He took a University of London external B.Sc. degree with first-class honours in chemistry in 1921 and M.Sc. in 1923, in which year he entered the photographic industry as research chemist to Thomas Illingworth and Co., Ltd. In 1938 he was appointed chief chemist and deputy director of research in Kodak, Ltd., and in 1953 transferred to the head office in Kingsway, London, where he was scientific liaison officer between Kodak, Ltd., and the Press.

He was always keenly interested in raising the standard of photography in Britain, and for the past three years he was responsible for the successful organization of the Kodak scholarships in colour and advanced photography.

His main contributions to photographic science were the devising of a number of new methods of analysis (which formed the basis of a thesis for D.Sc. (London) in 1928), advances in emulsion-making technology and the elucidation of the mechanism of fixation.

He was considerably interested in the work of scientific societies and had been vice-president of the Royal Institute of Chemistry and of the Society of Chemical Industry; but he was more closely connected with the Royal Photographic Society, of which he was twice president. In 1956 he gave the Royal Institution Christmas Lectures. He was the author of *The Science of Photography*, which quickly became a popular standard work of reference.

Among the appointments he held at the time of his death were principal of the London School of Medical Photography, chairman of the Photographic Information Council and member of the Photographic Advisory Committee of the City and Guilds of London Institute.

His leisure time interests included antique furniture and clocks and he was a member of the Antiquarian Horological Society.

Dr. Baines leaves a widow and two daughters.

NEWS and VIEWS

U.S. Presidential Award and Gold Medal : Prof. F. L. Whipple

PROF. FRED L. WHIPPLE, director of the Smithsonian Astrophysical Observatory, Cambridge, Mass., has been given the Presidential Award and Gold Medal for Distinguished Federal Civilian Service. The Award, the highest that can be bestowed on a career Federal employee, is being given to Dr. Whipple for his outstanding achievement in conceiving and developing "an optical satellite tracking system which stood ready to track the first artificial satellite launched and has since provided valuable scientific data". This network of twelve tracking stations, located on six continents, is still the most accurate tracking system in operation anywhere in the world. Dr. Whipple, who is also a professor of astronomy in Harvard University, has made major contributions to investigations of comets and meteors. He was the first person to propose that a 'meteor bumper' be placed about a spaceship to protect space travellers and astronauts from the danger of meteor punctures of a spacecraft. This proposal was made in 1946, eleven years before the first satellite was launched and fifteen years before the first man was placed in orbit.

Light Division at the National Physical Laboratory: Dr. L. A. Sayce, C.B.E.

DR. L. A. SAYCE, who was appointed in 1948 to the position of superintendent of the Light Division at the National Physical Laboratory, retires from this position on June 30 after fifteen years of distinguished service. He took a particular interest in the blending of basic and applied research, and nowhere was this more ably demonstrated than in his personal research on diffraction gratings. During his tenure of office, the Light Division has carried out much basic research on vision, colour and colour rendering, and there have been equally important advances in the more general fields of photometry, radiometry and optics, including the development of new forms of optical masers. The work on diffraction gratings which Dr. Sayce personally supervised has led to the availability of gratings of high efficiency both in the infra-red and X-ray regions, and out of this work an entirely new application of gratings has developed in their use as accurate scales of measurement. This has required a close study of moiré fringe techniques and has resulted in the extensive use of gratings in metrology and engineering. (He will be continuing and extending this aspect of his work for a further period in a special post which has been created for him at the National Engineering Laboratory.) Graduating from King's College, Newcastle upon Tyne, in 1922, Dr. Sayce took his Ph.D. in 1925. He was appointed lecturer in chemistry there in 1927, and his researches thereafter covered a wide range of interest in physical and inorganic chemistry, instrument design and photography. During the Second World War he served in the Ministry of Home Security, and for two years before joining the National Physical Laboratory, in 1948, he was assistant director of physical research at the Admiralty. He was created C.B.E. in 1958. Dr. Sayce is to be succeeded as superintendent of the Light Division by Dr. J. Dyson (see *Nature*, 198, 738; 1963).

Chemistry at Sheffield: Prof. R. D. Haworth, F.R.S.

PROF. R. D. HAWORTH retires from the Firth professorship of chemistry in the University of Sheffield at the end of this academic year. He had his early education in Stockport and then at the University of Manchester, where he came under the lasting influence of Arthur Lapworth. He proceeded with an 1851 Exhibition Scholarship to Oxford, to conduct very fruitful work on the synthesis of the isoquinoline alkaloids. From 1937 until 1939 he was lecturer in chemistry at King's College, Newcastle upon Tyne, where he carried out his extensive

R 333

investigations of those natural phenolic resins which formed the subject of his Tilden Lecture to the Chemical Society in 1942. Since 1939 he has held the Sheffield chair, directing important work, especially on the colouring matter purpurogallin and the chemistry of the tropolone system, and on the hydrolysable tannins. He has served as vice-president of the Chemical Society; he was elected to the Royal Society in 1944 and was awarded its Davy Medal in 1956. During the Second World War, and in the difficult years of expansion which have followed, Prof. Haworth has conducted the affairs of the Department with conspicuous vigour and skill. He collected an efficient and congenial team of academic associates and maintained good external relations to the advantage of the Department. The present impressive laboratories owe much to his inexhaustibly patient and knowledgeable co-operation with the architects. Prof. Haworth, who has been appointed Leverhulme Visiting Professor to India, is to be succeeded to the Firth professorship by Prof. G. Porter (see *Nature*, 198, 737; 1963).

The Imperial College of Science and Technology

Prof. P. M. S. Blackett has asked that he be allowed to relinquish the headship of the Department of Physics at the Imperial College of Science and Technology at the end of the present academic year. The Governing Body, in agreeing to this request, has recorded its great appreciation of his outstanding services in that position during the crucial years of the expansion of the College and the construction of the new physics building. Prof. C. C. Butler has been appointed to succeed Prof. Blackett. Prof. Butler, who has served on the staff of the College for ten years, has been a professor of physics since 1957. Prof. Blackett will remain as a professor of physics and as Pro-Rector of the College.

The Councils for Training of Health Visitors and Social Workers

Sir John Wolfenden has resigned from the position of chairman of the Council for the Training of Health Visitors and the Council for Training in Social Work following his appointment as the new chairman of the University Grants Committee. Sir Charles Morris, who is about to retire from the vice-chancellorship of the University of Leeds, has been appointed to succeed Sir John Wolfenden. The two Councils were set up last October, under the Health Visiting and Social Work (Training) Act, 1962. Under the First Schedule of the Act the Privy Council appoints one person to be chairman of both Councils.

The International Atomic Energy Agency and Trieste Centre for Theoretical Physics

An international centre for theoretical physics is to be established in Trieste in the first half of 1964 under the auspices of the International Atomic Energy Agency. The Centre will be established on a provisional basis; its work will be evaluated so that the Agency, after two years, can decide on the future direction of the Centre's activities. A further evaluation will be made to enable the Board to determine if it is desirable to move the Centre to a developing country after four years. The Italian Government has offered to construct a new building for the Centre and housing facilities for the staff and the fellows; it has further offered a cash contribution of 250,000 dollars per year for five years, staff services and fellowships. The International Atomic Energy Agency will contribute fellowships and professorships to an annual value not exceeding 55,000 dollars for four years and additional annual contributions not to exceed a total of 110,000 dollars in the same period.

The 1964 programme of work and budget for the International Atomic Energy Agency reflects a small increase over 1963. Administrative costs have been trimmed down further through a reduction in staff and decreased costs both for the scientific meetings and the sessions of the Board and the Conference. The Board recommends a regular budget of 7,444,500 dollars as compared with 7,337,500 dollars in 1963. For the operational programme, an expenditure of 2,367,500 dollars is proposed to be financed from voluntary contributions of 2 million dollars, special contributions, miscellaneous income and income from reimbursable services. The 2 million dollar target for voluntary contributions is the same as that of last year. The combined regular and voluntary budgets of 9,812,000 dollars do not include the funds made available to the International Atomic Energy Agency from the United Nations Expanded Programme of Technical Assistance, estimated at a little more than 1 million dollars.

United Kingdom Funds for Nuclear Energy Research

In a written answer in the House of Commons on June 17, the Parliamentary Secretary for Science, Mr. D. Freeth, stated that the United Kingdom was at present called on to pay about 23 per cent of the budget of the European Nuclear Energy Agency, but in the period 1957–62 only £155,000 of the £192,000 provided in the Atomic Energy Estimates was actually required. The contribution for the year ending December 31, 1963, was £30,000, but contributions to the Agency's joint project were separately assessed. It was not possible at this stage to give an estimate of the financial commitment of the United Kingdom to these projects. The commitment of the United Kingdom to the 20-MW *Dragon* project at present under construction at Winfrith was £10,200,000, of which £4,556,000 had been paid, leaving £5,644,000 to be paid over the period 1963–64–1966–67; £2,100,000 was provided in the 1963–64 Estimate. Some additional assistance was given in kind and in certain income tax liabilities of foreign staff attached to the project.

The National Reference Library of Science and Invention

At the report stage of the British Museum Bill in the House of Lords on June 18, when a motion providing for the separation of the National Reference Library of Science and Invention from the British Museum under a separate body of trustees was again pressed to a Division, a further amendment was moved by the Earl of Cranbrook requiring the new Library to provide the staff to operate a National Scientific Abstracting Service. The Earl of Cranbrook expressed the view that it would be essential for an abstracting service to be built around the new Reference Library, though he did not think that a complete abstracting service covering all the sciences was necessary or desirable. Moreover, he referred to a recommendation of the Council for Scientific and Industrial Research in its latest report that the Commonwealth countries and the United States should consider together the whole problem of science abstracting in English-speaking countries. For the Government, the Earl of Dundee said that the whole subject of technological abstracting had been considered by the British Commonwealth Scientific Council and a report was about to be issued. In the Patent Office Library a study was being made at the instance of the British Museum Trustees of the use of the scientific literature in the Patent Office as part of the planning of the new reference library. At the instance of the Advisory Council on Scientific Policy, Prof. B. H. Flowers was undertaking another study on the difficulties experienced by research workers in keeping up to date with new developments. The Earl of Dundee said that the Trustees recognized that it was most desirable that the new Reference Library should play a leading part in considering the adequacy of the coverage of existing abstracting systems, in setting up machinery for co-ordinating them, identifying overlaps and omissions and seeking all possible means of removing them. It was

also recognized that the development of electronic devices for storage and retrieval of information must be a main object of study in the new Library, and research was already proceeding into the possibility of collecting abstracts in punched tape form. Such a method might solve many of the problems of overlapping and delay in abstracts, and he thought the multiple use of the same abstracts should be encouraged rather than repeated abstracting of the same papers. In interpreting the amendment as implying a statutory obligation to provide a comprehensive national scientific abstracting service, which he did not regard as helpful, the Earl of Dundee was strongly supported by the Earl of Crawford, who argued that it would be better to await the outcome of the present enquiries, and regarded the proposal as damaging to the Library and a retrograde step. The amendment was, by leave, withdrawn.

The Commonwealth Development Bill

In moving the second reading of the Commonwealth Development Bill in the House of Commons on June 19, the Under-Secretary of State for Commonwealth Relations, Mr. J. Tilney, said that the Bill amended the Overseas Resources Development Act, 1959, and the Colonial Development and Welfare Act by returning to the sphere of activity of the Colonial Development Corporation—now to be renamed the Commonwealth Development Corporation—all Commonwealth territories within its scope when the Corporation was established in 1948. In accordance with powers conferred under the Bill, the Secretary of State will instruct the Corporation to seek his prior approval before starting operations in an independent country and that approval will only be given with the agreement of the Government concerned. It is not proposed to raise the amount which the Corporation can borrow from the Treasury above the limit of £130 million: net advances outstanding amount to £92 million, and in the past ten years borrowings have averaged less than £10 million per annum. Mr. Tilney said that the Corporation welcomed the policy embodied in the Bill.

On the colonial development and welfare side, the Bill extended the period in which such schemes could be made and Exchequer loans approved from March 31, 1964, to March 31, 1966, and increased from £315 million to £340 million the amount which may be spent on schemes under Section I of the 1959 Act. About £43·5 million remained unspent at March 31, 1963, so that about £68·5 million would be available for the three years 1963–66, and the provision for Exchequer loans was increased from £100 million to £105 million, permitting further issues of £41 million. Mr. Tilney pointed out that expenditure on research and development was now financed by the Department for Technical Co-operation and said that this change did not imply any decrease in research for the benefit of colonial territories. While the Bill was welcomed generally, Opposition speakers criticized the provisions as inadequate, but in replying on the debate for the Government, the Under-Secretary of State for the Colonies, Mr. N. Fisher, put the total of Government aid overseas during the next three years at £180–200 million a year.

Transition from Primary to Secondary Education

In a written answer in the House of Commons on June 17, the Minister of Education, Sir Edward Boyle, stated that when the Central Advisory Council for Education (England) had completed its present task, he proposed to reconstitute it with the following terms of reference: To consider primary education in all its aspects and the transition from primary to secondary education. In due course, he would ask the Central Advisory Council for Education (Wales) to consider the Welsh aspects of this enquiry and he was arranging for some common membership of the two Councils. Lady Plowden had accepted his invitation to become the next chairman of the Council, and the present chairman, Mr. J. Newson, had agreed to serve as deputy chairman of the reconstituted Council.

English Clearly Expressed

Prof. R. Hoggart's inaugural lecture, "Schools of English and Contemporary Society", delivered at the University of Birmingham on February 8, is concerned with emphasizing the practical importance and significance of a love and respect for language—which he regards as a prime duty of a school of English to foster (Birmingham: The University, 1963. 2*s*. 6*d*.). He insists that English has to do with exploring human experience in all its complexity and flux, and what he has to say about the changing meaning of words and the necessity of defining the meaning of words in the context in which they are used is highly pertinent to the scientist and his task of interpretation and exposition, whether it is a matter of exposition to his fellow scientists or to a wider public. Prof. Hoggart gives clear warning of the dangers which attend the careless use of words irrespective of the meaning which is likely to be attached to them by particular audiences or in particular circumstances. His lecture is as apposite in the context of discussions on the content of a general education as it is to the proper functions and value of a school of English.

United States Readings on Development

A Selected List of United States Readings on Development (Pp. xvii+363. Washington, D.C.: Agency for International Development. Obtainable from U.S. Government Printing Office, 1963. 1.25 dollars), prepared for the United Nations Conference on the Application of Science and Technology for the Benefit of the Less Developed Areas by S. M. Katz and F. McGowan, of the University of Pittsburgh, is a companion volume to the twelve volumes of United States papers prepared in connexion with the Conference (see *Nature*, 198, 250; 1963). Its thirteen chapters, containing almost 1,200 references, cover the regional planning experience of the Tennessee Valley Authority and Puerto Rico, production and marketing policies of great industrial enterprises, and the role of universities in concerting research and education in the service of human welfare. There is a short chapter on scientific and development policies, which includes sections on society and science and Government and science, but this is rather too limited in scope to be of service to any but the most elementary student of such subjects, though the chapter lists some references which are not generally known in the United Kingdom.

The Universities Federation for Animal Welfare

The Universities Federation for Animal Welfare has issued an interesting pamphlet setting out briefly some of the immediate interests that are given attention (*Some Things Done, Being Done, and to be Done*. Pp. 6. London: The Universities Federation for Animal Welfare, 1963). Included are: experiments on animals; pain in animals; the gin trap in Britain and overseas; cruel poisons; irresponsible shooting; whaling; correct technique for the electrocution of dogs and cats; tortoise trade; farm animals; anæsthesia; bull-fighting. Some indication of the manner in which the Federation undertakes its work is also given.

The Association of Consulting Scientists

At the annual general meeting of the Association of Consulting Scientists held in London recently the following honorary officers and members of council were elected: *Chairman*, Mr. F. G. Sarel Whitfield (Avebury Research Laboratories Ltd.); *Vice-Chairman*, Dr. H. H. Chambers (Sondes Place Research Laboratories Ltd.); *Honorary Treasurer*, Dr. G. W. Ferguson (Parry and Ferguson); *Honorary Secretary*, Mr. W. H. Stevens (Geochemical Laboratories); *Members of Council*, Dr. G. P. L. Miles, Mr. H. Pritchard, Mr. J. A. Radley (J. A. Radley Labora-

tories Ltd.), Dr. H. J. Stern (H. J. Stern's Laboratory Ltd.) and Dr. A. N. Worden (Huntingdon Research Centre). Dr. M. Barent (Barent and Johnson), the retiring chairman, was appointed liaison officer with the Union Internationale des Laboratoires Independant, to which the Association is affiliated as the United Kingdom and Commonwealth representative association.

Keilin Memorial Fund

The following statement has been received by the Editor of *Nature*: "With a number of our colleagues we have been considering how best to commemorate the scientific achievements of David Keilin. We believe that the establishment of a Keilin Memorial Lecture under the auspices of the Biochemical Society would perpetuate his memory and be of enduring value. It is hoped to hold the lecture every two years, and to realize this aim it will be necessary to establish a fund of £3,000 (8,400 dollars). The Biochemical Society has agreed to administer the fund". The statement is signed by Dr. B. Chance, Dr. M. Dixon, Dr. E. F. Hartree, Dr. R. Hill, Dr. T. Mann, Dr. M. F. Perutz, Dr. E. C. Slater, Dr. Emil L. Smith and Dr. P. Tate. Anyone wishing to contribute to the fund can obtain further information from Dr. E. F. Hartree, Animal Research Station, 307 Huntingdon Road, Cambridge.

U.K. Courses in Nuclear Energy, 1963–64

Under the heading of "U.K. Courses in Nuclear Energy, 1963–65" the May 1963 list of *Nuclear Studies*, compiled by the Science Department of the British Council, was noted on p. 1042 of the June 15 issue of *Nature*. The note refers to *List No.* 7 and not *List No.* 6 as stated. The note also mentioned that "The list has unavoidably appeared too late for application to be made for *any* of the courses for the academic year 1963–64". This is incorrect and should read "The list has unavoidably appeared too late for application to be made for *many* of the courses for the academic year 1963–64". Applications need not be submitted a long time in advance for many of the shorter courses. Furthermore, the *List* does not, in fact, include any courses for 1965, except by implication where courses are run annually.

University News:

Aberdeen

Dr. D. J. F. Bowling has been appointed to a lectureship in botany, and Dr. M. N. Court to a lectureship in soil science.

Durham

The seventeenth annual report of the University of Durham Appointments Board for 1961–62 reports that although significantly larger numbers completed courses in 1962 than in 1961, the demand in several sectors, notably chemical, oil and engineering industry, declined (Pp. 12. Durham: The University, 1963). As yet, the Board sees no signs that scientists or engineers, who would have reasonable prospects of success in, say, the Home Civil Service Administrative or Foreign Service competitions, are being attracted in those directions. Industrial demand for arts graduates also suffered a setback, but the arts graduate with reasonable personal qualities seeking employment outside teaching did not have an especially difficult time. The steady fall between 1958 and 1961 in the number of men joining nationalized industries and public utilities and corporations was reversed in 1962, and public service has increased its share of Durham graduates over the past five years. Reference is also made to the increasing numbers entering university employment, technical colleges and farm institutes, and the increased proportion of men graduates still seeking employment at the end of 1962 is attributed largely to the slack and uncertain state of the economy.

Liverpool

Prof. W. H. F. Barnes, professor of moral philosophy in the University of Edinburgh, has been appointed vice-chancellor in succession to Sir James Mountford, who retires on September 30.

London

The title of professor of chemical engineering has been conferred on Mr. S. B. Watkins in respect of his post at King's College. The title of reader in aeronautical engineering has been conferred on Dr. G. J. Hancock in respect of his post at Queen Mary College.

Announcements

Sir Isaac Wolfson, Bart., has been elected a Fellow of the Royal Society, under the Statute of the Royal Society which provides for the election of persons who either have rendered conspicuous service to the cause of science or are such that their election would be of signal benefit to the Society.

Dr. K. R. Payne has been appointed general manager of L. Light and Co., Ltd., with effect from May 16, in succession to Mr. G. R. Jones, who is leaving the Company.

The second International Pharmacological Meeting will be held in Prague during August 20–23. Further information can be obtained from the Secretariat of the Second International Pharmacological Meeting, Albertov 4, Prague 2.

The thirty-ninth annual Plant Pathology Field Meeting, arranged by the British Mycological Society, will be held at the East Malling Research Station on July 18. Further information can be obtained from Dr. R. C. F. Macer, Plant Breeding Institute, Maris Lane, Trumpington, Cambridge.

The thirteenth general assembly of the International Union of Geodesy and Geophysics is to be held on the campus of the University of California at Berkeley during August 19–31. Further information can be obtained from the Local Arrangements Committee, International Union of Geodesy and Geophysics, University of California, Berkeley, 4, California.

The fifth International Congress of Clinical Chemistry, organized by the American Association of Clinical Chemists and the Canadian Society for Clinical Chemistry, will be held in Detroit, Michigan, during August 19–23. Further information can be obtained from the secretary, Dr. D. G. Remp, Henry Ford Hospital, Detroit 2, Michigan.

The fourth Australian Spectroscopy Conference, organized by the Spectroscopy Committee of the Australian Academy of Science, will be held at the Australian National University, Canberra, during August 20–23. Further information can be obtained from Dr. S. R. Taylor, Department of Geophysics, Australian National University, Canberra.

An international conference on "Lattice Dynamics", organized by the Danish Academy of Technical Sciences, the Danish Physical Society, the International Union of Pure and Applied Physics, NORDITA, the U.S. National Science Foundation and the U.S. Office of Naval Research, will be held at the Technical University of Denmark, Copenhagen, during August 5–9. Further information can be obtained from Dr. S. Lundqvist, Department of Mathematical Physics, Chalmers University of Technology, Göteborg, Sweden.

Erratum. Referring to his communication in *Nature* of May 18, p. 678, Dr. S. M. Silverman writes that the times which he gave on the individual scales in Fig. 2 are incorrect. They should read, from top to bottom (U.T.): 1155, 1055, 1025 and 0955.

FOOD SCIENCE AT THE UNIVERSITY OF LEEDS

By Prof. A. G. WARD, O.B.E.
Department of Food and Leather Science

ON June 18, Mr. Lauchlan Rose, chairman of the Food Manufacturers' Federation, formally opened the extension to the Procter Department of Food and Leather Science of the University of Leeds. The name commemorates Prof. H. R. Procter, who founded, in 1891, the Leather Industries Department, the precursor of the present one. The additions constitute an increase in floor area of almost 50 per cent to a total of more than 18,000 sq. ft. They provide much-needed facilities for the 4-year course leading to the honours B.Sc. in food science, the inaugural year of which is just about to be completed, as well as for postgraduate research in food science.

Apart from offices, the main part of the extension is devoted to the food technology laboratories under the direction of Mr. G. Glew. The purpose of these laboratories is two-fold: first, to enable undergraduate students to handle small-scale equipment in order to obtain an understanding of the operations involved in food processing and, secondly, to provide facilities for research into technological problems of the food industry by undergraduates in their final year, research students, and members of the staff. The facilities of the laboratories include three refrigerated chambers, one controllable down to −29° C, a blast freezer, a small Leybold–Elliott freeze drier, a Kestner laboratory spray drier, a Kestner drum drier, and a Q.V.F. all-glass concentrator with a flavour recovery unit, together with a canning line and a variety of equipment for mixing, milling, baking, boiling and testing.

Attached to the laboratories is a room for bacteriological control work, much of which is carried out in collaboration with Mr. J. Wolf's Bacteriology Section of the Department of Agriculture. This work was illustrated by several exhibits.

Dr. R. Reed's electron-microscopy group with its Siemens Elmiskop II and a full range of ancillary equipment, including two ultramicrotomes, an ultrasonic disintegrator, and a metal shadowing unit, has been re-housed in the extension in a compact suite, and light microscopy, under Dr. F. Olga Flint, is catered for both on the under- and post-graduate levels. A Leitz 'Ortholux' microscope has just been acquired. The Biochemistry Research Laboratory's most prized piece of equipment is a Technicon automatic analyser, at present used for amino-acids, but shortly to be used on carbohydrates as well. A physics research laboratory and a final-year undergraduate laboratory complete the extension.

The previous addition to the Department in 1959 enabled facilities, such as a Spinco model *L* ultra-centrifuge, a Bellingham and Stanley photoelectric spectropolarimeter, and a light-scattering apparatus, to be installed. The present occasion provided the opportunity to add a Perkin–Elmer 237 infra-red spectrophotometer and a 451 gas chromatograph.

In connexion with the opening, the whole department as well as the new extension remained on view for three days, and some two hundred visitors were received. Special food science exhibits illustrated the methods adopted for undergraduate teaching and these included a display by Dr. R. Harper of the Psychology Department, who is responsible in the course for treating problems of perception with special reference to the sensory qualities of foods and food acceptance. A further display, on the history of the Public Analyst's work, was that by the City Analyst, Mr. R. A. Dalley, who lectured on food control aspects.

Present research on view included topics such as the electron microscopy of wheat gluten, the gelling of gelatin and pectin gels, and the isolation of the components of black-currant volatiles.

THE SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES

ANNUAL CONGRESS

AT the invitation of the Mayor and Corporation of Tunbridge Wells and the Tunbridge Wells Natural History Society, the South-Eastern Union of Scientific Societies held its sixty-eighth annual congress at Tunbridge Wells during May 9–12 under the presidency of Dr. W. S. Bristowe. The headquarters of the Congress was at the Public Library and Museum; the Young Naturalists' evening was held at the County Grammar Schools for Girls, by permission of the Headmistress.

The delegates were welcomed and entertained by the Mayor, Alderman Donald Savage, who reminded them that the Union was founded at Tunbridge Wells in 1896, only seven years after the town received its Charter. The Corporation takes great pride in its Museum, one of the first to stress the importance of local interest in the display of exhibits.

At the commencement of the Congress, the delegates were conducted on a tour of the town by Mrs. E. Bradley, who, on the route, described the Georgian houses and their past tenants, the origin and development of the Walks, now the Pantiles, and the cures (real and imaginary) obtained by taking vast quantities of the water from the chalybeate springs. Messrs. Boots kindly permitted the examination of the famous bath beneath the floor of their premises. A visit was made to the Church of King Charles the Martyr, where the change in its orientation was discussed.

A Young Naturalists' evening was held, and questions on a wide variety of natural history topics were answered by a team of experts under the chairmanship of Maxwell Knight, prizes being awarded to the girl and boy who submitted the best questions.

After the formal induction to the presidency, Dr. W. S. Bristowe delivered his address on "A Galaxy of Spiders". He commenced by saying how easy it was for a collector in towns to be suspected of misdemeanour. He had been disgraced near Hyde Park Corner where, seeing a prim and proper lady in distress, because of a spider hanging on a thread from her hair, he had removed it, opened his mouth and popped it in. The lady's expression of extreme disgust later became good-humoured. During his visit to Thailand he could not, at first, regard the delicacy of spiders with favour, but, when the feeling of repugnance was overcome, he found they tasted well. Discussing this with a Siamese gentleman, who had attended school in England, the same feeling had occurred when he was asked to eat British green raw vegetables and the decaying carcases of pheasants and hares.

As food, spiders are not poisonous and were used for medicine in early times. He instanced the case of Dr. Muffet's daughter, born 1540, who was treated for all ailments, internal and external, with concoctions of spider. It is possible from this the nursery rhyme of "Little Miss Muffet" evolved.

Throughout the ages human beings have had two reactions to spiders, admiration and fear. A protective mythology throughout the world still causes people to dislike killing spiders, and, in European countries, it is considered lucky to have them alight on one's clothes, a notion originating with the Greeks.

Spiders are of ancient stock, occurring in Carboniferous deposits perhaps 350 million years ago, and, in Asia, some eight species of living 'fossils' survive. Flies appeared 100 million years after spiders, and the first spiders fed on crawling things. These probably evolved wings to enable the avoidance of capture, then spiders spun nets to catch the flying insect; some insects then developed armour (beetles) through which the spider could not penetrate, some became distasteful and hundreds of species of spider would not eat them at all, and what may be described as an evolutionary battle was carried on. The spider population is enormous, millions per acre, and the weight of insects eaten every year is more than the weight of all the people in England. They are good at dispersing themselves, floating in the air on self-woven parachutes; Dr. Bristowe had found four species of spider on a remote arctic island. Although they had nothing corresponding to human intelligence, they had something equally remarkable, the knowledge of how to react.

In studying the mating habits, it is convenient to divide them into three groups: (1) long-sighted; (2) short-sighted; (3) webbed. In the long-sighted group the males are more fragile than the female and decoration has evolved and is displayed to attract the female. The short-sighted males use special grips, sometimes in the jaws, to ensure that once in contact with the female they must not lose her, in case they cannot find her again. The webbed type are rather like the long-sighted and also use a sort of 'Morse code' to attract the female, being able to pass sounds, as vibrations, along the strands of their webs.

The Archæological Section of the Union was addressed by the president, James Money, on "The Iron Age Hill Fort at High Rocks". He spoke of excavations he had carried out, under the auspices of the Sussex Archæological Society, of rock shelters and the fort, mentioning the help science can give to archæology which, in turn, can help science. Charcoal from the rock shelters had been examined by Miss Balfour Browne at the British Museum (Natural History) and the pollen analysis was carried out by Dr. G. W. Dimbleby at the University of Oxford.

The rock shelters were overhanging rocks on the escarpment of the Tunbridge Wells Sand (Lower Cretaceous) and the flint implements found indicated they were occupied during Mesolithic and Neolithic times, ranging approximately from 6000 B.C. to 1800 B.C. There were hearths of sandstone, heavily burnt, and examination of the charcoal confirmed the age arrived at by the artefacts.

At the fortified Iron Age camp, excavation revealed an area of 20 acres protected by double ramparts and ditches, the ramparts made of stone and earth, numerous post-holes showing the defences were strengthened by a timber palisade. A few fragments of pottery were found of the Southern 2*b* and 1*c* types. The outer ramparts were built in the second century B.C. by Wealden inhabitants to repulse the invasions of Belgic people from northern France and Belgium. The inner defences were constructed at the beginning of the first century A.D., and the finds included iron-ware, the upper part of a rotary quern of local sandstone and a fragment of Roman Samian ware. Evidence of agriculture on the site consisted of pollen grains of wheat; a number of hearths, some with layers of charcoal 6 in. thick, were discovered 15 in. below ground-level. Extensive excavation has been carried out at the east entrance, revealing triple fortifications, a paved pathway and an ancient trackway.

The president of the Zoological Section, Prof. H. R. Hewer, chose as the title of his address "Seals". He said he proposed to speak mainly about the grey seals as, during the past ten years, our knowledge of them had greatly increased, for in a book published in 1926, of twenty-six statements regarding them, twenty-two were completely wrong. The methodical examination commenced in 1950 off the coast of west Wales, for the matter had become a political issue through the complaints of depreciation caused by seals from fishermen of north-east England and south Scotland. The matter is now taken seriously, and a responsible officer, J. Smith, of the Nature Conservancy, is stationed in the Orkneys, where the largest colony in the British Isles occurs; as many as 3,000 cubs are born each year. A variety of interests calls for control of a large natural population. When an area is completely protected there is a danger from epidemics and the death-rate increases—the mortality-rate rises to 35 per cent in the first few days of their life. The cubs during the first fortnight of their lives increase in weight from 35 to 90 lb., mostly in blubber, and should a cub leave the breeding ground before reaching this weight it will not survive. Not a single young seal of the hundreds either shot or caught in nets, by people interested in the salmon fisheries, weighed more than 70 lb. In a colony of 1,000 of each sex, a thousand cubs would be born if all the cows became pregnant, and as the cows, on average, live 35 years and the bulls 25 years, controlled preservation is necessary if the colony is to be successfully established. Age is determined by the examination of thin sections, transverse and longitudinal, of the teeth. The weight of the bull must be considerable when it reaches the breeding territory, for it is without food for 6–8 weeks, living on its blubber. The territory of each bull is vigorously guarded against invasion by other bulls, and there are 7–10 cows to each bull; a specimen bull measured 90 in. in length and weighed about a quarter of a ton. Bulls mature in six years and cows in five years; cubs are produced in the following year. Prof. Hewer concluded his address with a commentary on a film he had taken on the Island of Shillay.

Dr. R. Casey, as president of the Geological Section, gave an address on "The Dawn of the Cretaceous Period in Britain". He said that from time to time some new find throws light on an obscure geological problem and permits reassessment of a boundary, such as the one he proposed to discuss, the Jurassic–Cretaceous. Across northern Europe are signs of concerted movements of the sea which indicate a natural starting point of the Cretaceous period. This affects ideas of the geography of Britain in remote times and on the grouping of the strata.

Three separate basins received deposits spanning the Jurassic–Cretaceous boundary: (1) Southern (Kent–Dorset–Bucks.); (2) Spilsby (Lincolnshire–Norfolk); (3) Speeton (Yorkshire). The ammonites of the Spilsby Sandstone show there is no missing interval in the Jurassic marine record in Britain. Genera of ammonites which occur in the Portland of southern England and the Volgian of the U.S.S.R. are also in the lower part of the Spilsby Sandstone. Dr. Casey traced the development through the Portland–Purbeck regression and the incoming Cretaceous tide and said that the Cinder Bed makes a firm datum. He suggested that the advancing Cretaceous sea re-opened the connexion between the Spilsby and Southern basins, flooding the Purbeck swamps and laying the Cinder Bed as the bedrock of the Cretaceous system in southern England; evidence from continental Europe confirmed this view. In conclusion, Dr. Casey said that all lines of evidence lead to the idea that a single advance of the sea initiated the Cretaceous Period in northern Europe, and to overcome nomenclature difficulties he would suggest 'Lulworth Beds' for the sequence

between the Portland Stone and the Cinder Bed, and 'Durlston Beds' for the sequence from the base of the Hastings Beds down to, and including, the Cinder Bed; the former grouped with the Portland Beds, the latter a subordinate and basal division of the Wealden Beds.

Favourable weather enabled the full excursion programme to be carried out: the botanists visited High Rocks and Eridge, the archæologists were conducted to the Rock Shelters and Iron Age camp at High Rocks by J. Money, while the geologists examined beds within the Wealden, in the vicinity of Tunbridge Wells, under the direction of Dr. R. Casey, who dealt especially with the relation between the Wadhurst Clay and the Tunbridge Wells Sandstone.

The excellent arrangements for the Congress were undertaken by the Tunbridge Wells Natural History Society, for whom Mrs. D. Vernede acted as honorary secretary.

F. J. Epps

THE MATHEMATICAL ASSOCIATION

ANNUAL CONFERENCE

THE Mathematical Association's annual conference held at the University of Nottingham in April was outstanding for the high level of interest sustained throughout the sessions. The Association's membership continues to rise steadily and now stands at more than 5,000.

In his report on current affairs. Mr. Combridge spoke of the formation of the Joint Mathematical Council of the United Kingdom which was announced in the Press on April 3. The Council has set up a fact-finding committee to investigate proposals for setting up an Institute of Mathematics.

The Conference on Mathematics in Education and Industry, of which Mr. Combridge is chairman, had held a meeting on March 23 and had adopted the report of its working party. This report was being abbreviated into a pamphlet which he hoped would be circulated to members of the Mathematical Association this summer. The Conference gave its blessing to a scheme put forward by Mr. B. T. Bellis of Highgate School to form a group of schools which would form links with industry which might assist, in particular, with the teaching of mathematics in the later years of school. Mr. Combridge emphasized the need for strengthening the links between schools and industry, and between schools and training colleges and departments of education.

The Universe

In his presidential address, Prof. V. C. A. Ferraro reviewed the advances made in our knowledge of the universe since Galileo first directed his newly made telescope to our nearest neighbours in space. Galileo's discovery of the satellites of Jupiter demolished the last remaining vestiges of the Ptolemaic system. Then followed the rise of descriptive astronomy associated with the remarkable researches of Sir William Herschel, who stressed the need to build large telescopes for a better understanding of the architecture of the universe. He also suggested, with remarkable insight, that the problem of the Milky Way might be resolved by supposing that the stars extended much farther into space along the plane than in the direction of the poles, so as to appear as a great mass of stars along its edge.

The nineteenth century saw the rise of astrophysics and the use of the spectroscope in unravelling the physical conditions of the stars. The classification of stars according to their spectral classes attained its most important form in the so-called Hertzsprung–Russell diagram in which the luminosities of the stars are plotted against the structural classes. The points are found to lie in a narrow belt running diagonally from the brightest stars to the faint red ones, now known as the mean sequence. This diagram has proved invaluable in the study of stellar evolution.

Our knowledge of the structure and size of the universe could only be obtained by the use of large telescopes and principally by the 100-in. telescope at Mount Wilson and the 200-in. telescope at Mount Palomar. They reveal that the Milky Way consists of hundreds of billions of stars arranged in a flattened disk so large that it would take light travelling at 186,000 miles a second 100,000 years to cross the disk. Herschel had long ago suspected that the nebulosities seen in the Milky Way might be systems of stars similar to our own, but lying outside it. His conjecture was amply confirmed by Hubble from his observations at Mount Wilson. Our nearest nebula, Andromeda, is two million light years away from us, while the farthest nebula so far photographed with the 200-in. telescope at Mount Palomar is about two thousand million light years away. Radio telescopes have probed even farther into space to distances of the order five thousand million light years. Within this great expanse there are probably thousands of millions of these galaxies the distribution of which appears to be uniform in space.

Early in 1930 an observation by an electrical engineer, Jansky, marked the beginning of the study of the new science of radio astronomy. He detected some radiation in the decimetre wave-length which he was convinced came from outer space since the signals he received were not observed at the same time on consecutive days but were observed 4 min earlier each day, corresponding to the lapse of a sidereal day instead of a solar day. Jansky's discovery did not occasion much enthusiasm at the time and it was left to an amateur, Reber, to confirm his conclusions. Later still it was recognized that radio signals could be picked up from regions of space farther away from us than would be possible by observations from optical telescopes. Some of the radiation is now known to originate in the interstellar gas, and a brilliant prediction by the Dutch astronomer van der Hulst that this was radiation of 21-cm wave-length emitted by hydrogen clouds in interstellar space was confirmed by his Dutch colleagues. By this discovery it was recognized that our galaxy has a spiral structure very much like that of the great Andromeda nebula.

Prof. Ferraro then referred to the first-fruits of space research and in particular the discovery of the high-energy particles trapped in the Earth's magnetic field and known as the van Allen radiation belt. This consists of two belts, the inner one, at about 2,000 km from the Earth, being quite stable and generally believed to be produced by neutron decay, while the outer belt, extending from three to five Earth radii or more from the Earth, consists for the most part of high-energy electrons. This is rather variable, especially during magnetic storms.

Recent flights by space probes have also shown the absence of a magnetic field on the Moon and Venus and the high temperature on this planet. In the foreseeable future it seems unlikely, however, that space probes could travel much beyond the confines of the Solar System and that, so far as could be seen, space exploration by probes and satellites was a limited venture. Further knowledge of the vast universe around us must still be derived from observation by conventional optical and radio telescopes.

Prof. Ferraro then briefly referred to cosmological theories which had been proposed and noted that there were, at the present day, two rival theories in the field, the evolutionary theory and the steady-state theory.

In the evolutionary theory the universe evolved from a single act of creation in which the whole of the universe was contained in a primeval atom. Because this high concentration of matter was highly unstable the atom exploded with great violence. After a certain period the matter settled down sufficiently for gravitational force to introduce some degree of stability. Thereafter the galaxies became subject to a repulsion represented by the cosmical constant, so that the galaxies began to recede from one another with speeds proportional to their distance apart in accordance with the observed Doppler shift. In the steady-state theory, although galaxies recede beyond the observable horizons, other galaxies will be formed to take their place so that the universe always presents the same aspect. To maintain this steady-state, the advocates of the steady-state theory have had to invoke that matter, in the form of protons, is continually being created at the rate of about one proton per cubic mile of space per year.

Attempts to discriminate between the two theories by observation of numbers of radio sources in space have so far not proved very conclusive. Prof. Ferraro pointed out that in spite of its many attractive features the steady-state theory, in the form proposed by Bondi and Gold, violates the principles of energy and momentum. There is so far no reason to doubt that these principles are valid universally, and to obviate this feature of the theory Hoyle has proposed a variant in which an as yet undiscovered field of force is invoked. Hoyle's theory has the merit of retaining these conservation principles.

Mathematics in Technical Education

A discussion on mathematics in technical education was opened by Mr. D. G. Toose, who outlined the structure of technical education. The mathematics courses aim at showing the students the theoretical structure of their technology and include basic courses in mathematics.

In the past few years there has been a demand for mathematicians as technologists in their own right. They need to be competent mathematicians with an ability to convert a physical situation into a mathematical statement. At present the training of an industrial mathematician may be by a course at a university or at a college of advanced technology. Higher National Certificate and Diploma schemes exist, but at present there is no mathematical institute to award a professional qualification comparable with those available to engineers.

Dr. Kerr spoke of the Diploma in Technology in mathematics. The colleges take great care in placing students in industry for the industrial part of their training whose success depends on co-operation between the college and the firm concerned. The problems set in college have to be somewhat artificial so that they can be solved in two or three hours, but from the beginning of their time in industry the students see how problems really occur; this gives them considerable motivation for the academic work on return to college.

The academic courses have honours degree standing. A general course is followed by specialization later. Numerical analysis, statistics and computing are usually introduced early in the courses. Geometry and modern algebra tend, as a result, to get less time than is usual in university mathematics courses. Dr. Kerr was able to report the average attainment at entry as rising.

Continuing the discussion on mathematics in technical education, Mr. M. Bridger pointed out that there are full-time degree courses available at a large number of colleges of technology. Young people are becoming increasingly aware of the opportunities for programmers, numerical analysts and systems analysts. Some dozen colleges have installed computers and some half-dozen are completing their installations in the near future. An adequate number of mathematicians with industrial experience have taken up teaching posts so that a reasonable number of colleges of technology are in a position to offer courses in industrial mathematics. The trend in these and other courses is away from part-time study.

New Developments in the Teaching of Mathematics

Opening a discussion on new developments in the teaching of mathematics, Mr. A. P. Rollett referred to work being done by schoolmasters in different parts of Britain and went on to speak of the work of the School Mathematics Project of which Prof. B. Thwaites is director. It is clear that he has been influenced a little by activities in the United States. There is no objection to this, provided it is clearly realized that conditions are vastly different and that the real difficulty in the United States is a shortage of suitably qualified teachers. In Britain there are still enough of sufficient calibre to be able to discuss with university teachers what topics are desirable and feasible in the schools. With regard to the reforms advocated by recent publications by the Organization for European Co-operation and Development, Mr. Rollett quoted Prof. R. L. Goodstein's review in the February 1962 issue of *The Mathematical Gazette*, and he went on to contrast the classroom atmosphere in the United States, France and England. In Britain traditions exist, and the immediate need is more recording and publication of teachers' impressions and pupils' reactions to new work done in the schools of Britain.

Dr. A. G. Howson, of the University of Southampton, explained that the School Mathematics Project has concentrated on one of a number of present-day problems: How can new mathematical topics be introduced into the syllabuses and syllabuses be designed that are more relevant to present conditions? It is hoped to encourage more pupils to pursue the study of mathematics further and it is also hoped to bridge the gulf which at the moment separates university from school mathematics. One of the major changes made by the School Mathematics Project has been in the increase in the algebraic content of the school course. The aim has been to convey something of the nature of the concepts involved rather than to impart a definite body of knowledge. Euclidean space is studied by means of geometrical transformations and the teaching of geometry by rote is discouraged. Another important part of the syllabus is the introduction to probability and statistics in which it is hoped to show how data can be collected and displayed, and what conclusions can be logically drawn from them. Throughout, the emphasis has been shifted towards mathematical ideas and away from the acquisition of techniques.

Mr. C. Hope told the conference of the origins of the Midland Mathematics Experiment. He outlined some of the aims of the syllabus: the pupils must be able to solve problems which have arisen in the past; the problems must arise out of the experience of the children; and any topics which are included should have the widest possible applications in science, mathematics, industry, commerce, etc.

The syllabus of the Midland Mathematics Experiment includes the algebras of sets and vectors, vector geometry and matrices, calculus, stage *A* probability, and arithmetic applied to real living and the solution of problems. Mr. Hope spoke of the advantage it would be both to examining bodies and to schools if there could be formed a joint sub-committee which would examine proposed syllabuses so that experiment should not be hindered by the fact that neighbouring schools are often examined by different boards. He suggested that a series of courses should be held at regional centres to consider what can be done with ordinary children, and to stimulate teachers to experiment in their own schools.

Among the other lectures, Mr. G. A. V. Leaf gave an absorbing and refreshing account of some of the practical problems of the hosiery industry, Prof. H. Bondi gave an absorbing lecture in which he introduced special relativity from an unusual point of view, and Prof. D. B. Scott gave a vivid introduction to some of the ideas of topology.

Elections

At the annual general meeting, the election of Mr. J. B. Morgan as president for 1963 was announced. Mr. R. E. Green was elected honorary treasurer and the honorary secretaries, Mr. F. W. Kellaway and Miss R. K. Tobias, were re-elected. Dr. E. A. Maxwell was elected as editor in place of Prof. R. L. Goodstein, who remains honorary librarian. Mr. B. J. F. Dorrington and Dr. E. Kerr were re-elected, and Mr. J. K. Backhouse, Miss E. M. Holman and Mr. C. Steele elected as honorary assistant secretaries. This represents an increase of two assistant secretaries, which reflects the growing amount of work being undertaken by the Association; the annual subscription was raised to 30*s.* in order to finance the Association's commitments. Mr. N. De Q. Dodds was re-elected as honorary assistant treasurer. J. K. BACKHOUSE

THE DANISH ATOMIC ENERGY COMMISSION

THE annual report of the activities of the Danish Atomic Energy Commission for the period April 1, 1961–March 31, 1962*, consists of six chapters dealing respectively with the construction at the Risø Research Establishment; the recent work of the Establishment; international co-operation in the peaceful use of nuclear energy; geological surveys in Greenland and other activities; the technical and administrative organization of the Commission; and the financial accounts of the Commission. The text of Act 170 of May 16, 1962, on nuclear installations (atomic plants), the list of publications and of papers written by members of the staff during the year under review, and a map of the Risø Research Establishment, form annexes to the report.

Eight meetings were held by the Commission, and thirty-six by the Executive Committee during the year. There was no alteration in the membership of the Commission and all members were re-appointed for the period of three years commencing February 1, 1962, with the exception of Profs. J. Bøggild and H. H. Jensen, whose terms of office did not expire until February 1, 1963. The late Prof. Niels Bohr was chairman and Dr. H. P. Christenson vice-chairman of the Commission, with Mr. H. H. Koch, permanent under-secretary of State, chairman of the executive committee. The staff on March 31, 1962, numbered 723, of which 495 were employed in the technical and scientific divisions. The workshop staff consisted of 41 people, including seven apprentices, under the direction of a superintendent, and the library staff of 14 people, headed by the librarian.

The Commission's research activities, which were considerably extended during 1959–60 when the large reactor *DR*3 was completed, have continued to develop and have led in particular to the accomplishment of several joint research projects in co-operation with atomic energy establishments in various countries and with European joint enterprises. Irradiation experiments for the *Dragon* project have been carried out on certain steel samples in the research reactor *DR*2, and work has continued on graphite and uranium irradiation experiments in co-operation with the United Kingdom Atomic Energy Authority.

In the physics department of the Establishment, which houses the meteorological station, the reactor *DR*1, and the linear accelerator, a number of practical courses were held for students from the Technical University of Denmark, for students from the Universities of Århus and Copenhagen, for engineers employed in industry and for operators attached to the reactor *DR*2. The linear accelerator was used for experimental irradiation for both industry and the department. In addition, the sterilization by irradiation of medical equipment, including blood transfusion sets, female catheters, artificial lungs and disposable hypodermic syringes, was undertaken for individual firms. The meteorological station continued its investigation of the meteorological conditions in the lower layers of the atmosphere and the data collected were processed statistically. The neutron crystal spectrometer attached to the reactor *DR*2 was used to measure the total cross-section of organic coolants. A start has been made on the construction of a triple-axis crystal spectrometer for solid-state physical examinations. A low-temperature laboratory is being built and measurements made on superconductive materials. Other work in solid-state physics includes the study of the transport properties of pure metals.

The electronics department was largely concerned with the development and assembly of instruments, but in addition a study was made of tunnel diodes and their use in nuclear instruments, especially discriminators. During the summers of 1961 and 1962 the airborne scintillometer developed by the electronics department was tried out with promising results by the Greenland Geological Survey. The reactor engineering department was occupied with the helium heat transmission experiments *HTTC* for the *Dragon* project, and the organic heat loop was completed. Activities in connexion with the deuterium moderated, organic cooled, reactor (*DOR*) project, included the construction of fuel elements, the hot-cell facility and apparatus for experiments with some of the components for the primary cooling circuit. The reactor physics section, which consists of a theoretical reactor physics group, an experimental reactor physics group and a computer group, concentrated its attention on calculations and measurements in relation to the *DOR* project. A major effort was made to prepare computer codes for use in *DOR* calculations, and, during the year under review, codes were prepared for the calculation of the thermal utilization factor, resonance escape probability, fast-fission factor, and Fermi age. The main tool of the computer group is to be the digital computer *GIER*, which was produced by the Danish Institute of Computing Machinery and which was installed at the Risø Establishment during February 1962. The fast memory of *GIER* contains 1,024 words, each of 42 binary digits, and its magnetic drum memory contains 12,000 words. The addition time is 50 μsec.

The results of the attempt by the chemistry department to obtain, by examination on a laboratory scale, suitable processes for a continuous extraction method for the utilization of the uranium and thorium deposits in Greenland were encouraging. In addition, calculations of the investment and operation costs of an extraction plant showed that the economic use of the deposits in the future is a possibility, and some 200 tons of ore were therefore mined and brought to Risø during 1962 for further experimentation. The radiolysis and pyrolysis of terphenyls, of importance in connexion with the *DOR* project, were studied and the decay schemes for arsenic-78, metastable indium-116 and lanthanum-140 were investigated. The radiochemistry of proteins, the possibility of separation of uranium isotopes in a Ranque–Hilsch vortex tube, and the use of electron spin resonance are some of the other activities of the department mentioned in the report.

During the period under review, more than 6,000 people visited Risø and were shown around the Establishment on conducted tours. The scientific staff of the Commission have co-operated in the teaching at institutes of higher education and several physics courses have been held for primary school teachers and technical college teachers.

* Report on the Activities of the Danish Atomic Energy Commission for the Period from 1 April, 1961, to 31 March, 1962. Pp. 84. (Copenhagen: Danish Atomic Energy Commission, 1962.)

In collaboration with the University Extension Committee of the Technical University of Denmark a series of lectures entitled "Atomic Energy—its Implications and Utilization" have been given in Hjørring and Elsinore. The Library issued 24,014 items on loan during the year, and 2,045 books, periodicals and reports were borrowed from other libraries. On March 31, 1962, the total holding of the Library consisted of 95,000 bibliographical units, of which 30,000 were on microcards.

S. Weintroub

RADIATION HAZARDS IN PERSPECTIVE

THE Expert Committee on Radiation of the World Health Organization consists of a group of international experts under the chairmanship of Lord Adrian. The Committee, together with representatives of several other organizations, met in Geneva during October 24–30, 1961, to discuss the relative somatic and genetic effects of ionizing radiation and of other agents and substances in our environment which have toxic, carcinogenic or mutagenic properties. The report of that meeting has now been published*.

Prominence has been given in recent years to the hazards of ionizing radiation and intensive studies have been made of radiation injuries and elaborate protection measures devised. Emphasis, however, should also be given to the beneficial aspects of many procedures involving radiation exposure, for it is well known that the benefits of the appropriate medical use of radiation in diagnosis and therapy far outweigh the hazards. With adequate protective measures, radioactive materials and nuclear energy can be peacefully and usefully applied in industrial and technological fields.

The report warns that preoccupation with the problems of radiation hazards may obscure the fact that there are many other toxic agents in the environment, some very widespread, which could prove a greater menace to public health. Man-made hazards to health must be reviewed against the background of known or unknown causes of disease, co-extensive with the whole field of medicine. In less-developed areas, man-made hazards account for only a small proportion of illness, but in highly developed areas they are responsible for a significant fraction of illness and death. The statistics given in the report show that in many countries accidents rank third as a cause of death and constitute the leading cause of death in the younger and more productive age groups. Most of the reported injuries caused by chemical toxins have occurred in industry, but increasing attention is being directed to the dangers of air pollution, pesticide residues in food, and food additives. A wide variety of chemical compounds are now known to be carcinogenic and others have been shown experimentally to be capable of genetic changes.

Turning to self-imposed hazards, the report states that it appears quite obvious that cigarette smoking or something closely associated with it is largely responsible for the high incidence of bronchiogenic carcinoma in certain countries. Some anomalies in the geographical distribution of lung cancer strongly suggest that other agents are partly responsible. The most substantial evidence appears to be the higher incidence in urban than in rural smokers. The medical use of radiation for therapy of non-malignant conditions and of diagnosis, where, in the early days of radiological practice, excessive doses may have been given, has occasionally been shown to lead to malignant disease, and there is still need for care and research in this field. The genetic effects of radiation, chemicals and temperature are discussed in some detail. The total incidence of hereditary diseases and defects in man may be estimated at about 6 per cent of all live births. The discovery recently that a surprisingly high frequency of defects in man are associated with anomalies of chromosome number or structural aberrations of the chromosomes suggest, since such types of abnormalities can be produced by radiation, that radiation hazard is more extensive than suspected before. The role of mutation in maintaining the hereditary burden in man is still under debate and an answer is likely to be arrived at very slowly. Mutations in all animals and plants occur naturally, and although the causes of these spontaneous mutations are not well understood, it is estimated that only a small fraction could be due to the natural background radiation to which all living things are exposed. There is no *a priori* reason for believing that ionizing radiation is the only, or even the main, environmental factor in the production of mutations. Some hundreds of chemical agents are known to be mutagenic, but none has been investigated in such detail as radiation. The report calls for more research to assess the genetic hazards of mutagenic chemicals and temperature.

In their concluding remarks, the Committee recommends that studies be undertaken to establish criteria for safe exposure-levels to toxic agents, both for individuals (as in the case of occupational exposure) and for populations (as in the case of pollution of water, food and air). The suggestions that certain chemical agents may have deleterious somatic and genetic effects similar to those produced by ionizing radiations should be investigated, and the international standards of statistical reporting of effects, damage, disability and death because of toxic materials should be improved. In addition, epidemiological and genetic studies of the effects of toxic materials should be made and intensive research stimulated on the mechanism of action of these materials including their carcinogenic and genetic effects.

TOBERMORITE GEL IN CONCRETE

TOBERMORITE is now known to be the chief cementing compound in hardened Portland cement and its structure largely determines the properties of concrete. When Portland cement is mixed with a limited amount of water, a plastic, mud-like material called 'cement paste' results; it sets in a matter of hours, becoming reasonably firm, then continues to harden for a period of months, if not years. The hardened paste is the matrix into which the fine and coarse crushed rock or natural sand and gravel enter, thus forming the artificial rock called concrete. Stephen Brunauer, of the Portland Cement Association, Illinois, discussed the role of tobermorite gel in concrete at a lecture to the Institute of Civil Engineers in London in July 1962 and a transcript appeared in *Structural Concrete* (1, 7; January/February, 1963); this has since been reprinted for the Cement and Concrete Association, London.

Brunauer's thesis is briefly as follows. Portland cement is a complex mixture of eight or more compounds of which the two most important are known to be tricalcium silicate (Ca_3SiO_5) and β-dicalcium silicate (β-Ca_2SiO_4), these two silicates constituting about 75 per cent of an

average Portland cement by weight. Reaction of either or both these silicates with water produces similar calcium silicate hydrates but with different amounts of calcium hydroxide. The calcium silicate hydrate is similar to the natural mineral known as tobermorite and is now designated as tobermorite gel, the most important constituent of hardened Portland cement paste, hence of concrete. "Tobermorite gel plays a vital role in determining the rheological or flow properties of fresh cement paste, which properties in turn determine the consistency and workability of fresh concrete. It plays a dominant role in the setting and hardening of the paste and in determining the strength and dimensional stability of hardened paste and concrete. For these reasons I have called tobermorite gel the 'heart of concrete'."

Examination of hardened tricalcium silicate paste after complete hydration suggests the following stoichiometry of the reaction: $2(3CaO.SiO_2) + 6H_2O = 3CaO.2SiO_2.3H_2O + 3Ca(OH)_2$. Dicalcium silicate reacts with water much more slowly than tricalcium silicate and the examination of a mature, four-year-old dicalcium silicate paste can be represented by the equation: $2(2CaO.SiO_2) + 4H_2O = 3{\cdot}3CaO.2SiO_2.3{\cdot}3H_2O + 0{\cdot}7Ca(OH)_2$. Thus the lime/silica ratio in tricalcium silicate is 3, in dicalcium silicate it is 2. Tobermorite gel obtained from tricalcium silicate does not have the same composition exactly as that obtained from the dicalcium silicate, but otherwise the two gels are similar, having the same X-ray diffraction pattern, and when examined with the electron microscope the gel particles look the same. There is, however, in the specific surface area of each a marked difference. It is the nature of the surface and the extent of that surface which combine to determine the cementing power of tobermorite gel. H. B. MILNER

TOTAL TRAPPING OF CHROMATOGRAPHIC EFFLUENTS IN ARGON CARRIER GAS

By DR. P. A. T. SWOBODA

Low Temperature Research Station, Downing Street, Cambridge

THE quantitative collection of fractions in preparative gas chromatography is difficult because of the tendency of the sample to condense into fog particles which are then swept by the carrier gas through the collecting trap[1]. This difficulty is avoided if a method of trapping is used in which there is total condensation of the carrier gas together with the sample, followed by low-temperature evaporation of the condensed gas without loss of the frozen sample. Liquid nitrogen (b.p., −196°) is used as the coolant to condense argon (b.p., −186°). Since on liquefaction there is about a thousand-fold diminution of volume considerable amounts of carrier gas may be collected in a small simple trap.

If a closed vessel cooled in liquid nitrogen is connected to the exit of the chromatograph the condensed argon has such a low vapour pressure (*c.* 200 mm mercury at −196°) that a partial vacuum is applied to the detector and column outlet with a consequent disturbance of the operating parameters of the separation. Usually the exit of the chromatograph is at atmospheric pressure and this is achieved by venting the trap to the atmosphere. The reduced vapour pressure of argon on condensation then results in a back-flow of air into the trap, where it is also condensed. With the apparatus shown in Fig. 1 continuous back-flow rates of air between 200 and 400 ml./min were observed with argon in-flows ranging from 11 to 310 ml./min. To prevent contamination by atmospheric pollutants and to reduce the extra volume of liquid collected, it is preferable to allow pure nitrogen gas to be sucked back. This is most easily achieved by connecting the outlet of the trap to a length of glass tubing the end of which dips under the surface of liquid nitrogen. Back-flow rates of between 75 and 200 ml./min of nitrogen gas were observed with argon in-flows ranging from 11 to 600 ml./min. There must, of course, be an upper limit to the rate of flow of argon which can be completely condensed in a particular design of trap and this is solely determined by the rate of heat transfer to the coolant. That this is high is indicated by the fact that in every experiment where initially argon was passed through the 'Drechsel' tube trap at room temperature, the reversal of flow at the outlet of the trap occurred within 5–10 sec of immersion in liquid nitrogen.

Quantitative recovery of the frozen sample on evaporation of the liquid argon–nitrogen mixture is achieved if the input of heat is not so excessive as to cause explosive vaporization, and the ultimate temperature attained is not so high that the sample has a considerable vapour pressure. The simplest procedure is to transfer quickly the trap, with its inlet now closed and the outlet vented to the atmosphere, to a 150 × 25 mm test-tube half-filled with liquid nitrogen. After standing for a few minutes the liquefied gases have evaporated and the trap will eventually attain room temperature. To limit this final temperature rise the test-tube may be immersed in a suitable cryogenic mixture (for example, melting pentane at −131°). For extremely volatile samples it is preferable

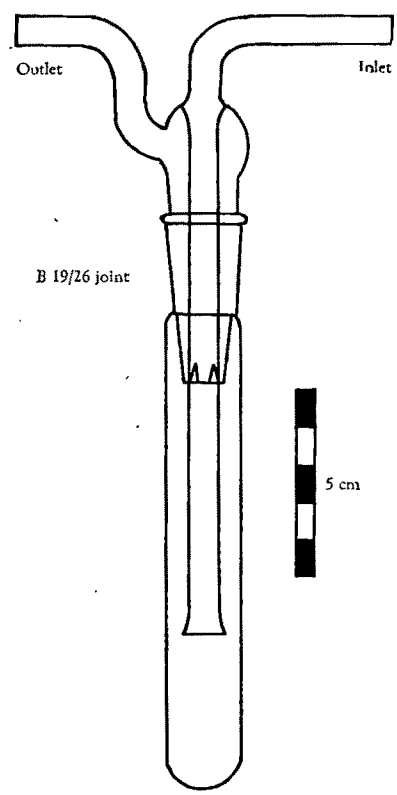

Fig. 1. 'Drechsel' tube used for total trapping. Not shown are the retaining spring and the silicone rubber tubing connexions sealed by Mohr's spring clips

to use liquid oxygen (b.p., −183°). That no loss of sample has occurred may most conveniently be confirmed by connecting a second trap with its outlet closed and re-condensing the total effluent gases, repeating the evaporation and assaying the residue.

Recoveries of 100±3 per cent, usually quantitative within the precision of assay, were obtained with 0·6–26 mg samples of acetic acid, anisole, benzene, hexanal, phenol and propanal. While no loss of acetic acid or of phenol into the second trap was observed when using the pre-cooled test-tube procedure of controlling evaporation, benzene required the use of the melting pentane cryostat. The effectiveness of limiting the rise in temperature is best illustrated by the finding that less than 5 per cent of the sample in the first trap was transferred to the second trap for hydrogen sulphide when using the cryostat, and for ethane when using liquid oxygen.

The design of trap shown in Fig. 1, which consists of a Quickfit 'Drechsel' head *MF*28/2 with shortened stem inserted in an *MF*24/2/6 test-tube, was chosen because it may conveniently be rinsed with small volumes of solvent and yet has sufficient capacity to contain considerable amounts of liquefied gas without development of hydrostatic pressure gradients. Moreover, during the evaporation step the effluent gas does not pass through the inlet tube and therefore cannot cause loss of the sample which may have partly condensed there.

The ease with which quantitative recoveries are obtained by this procedure of total trapping suggests its application not only to preparative gas chromatography but also analytically in combination with independent chemical or physical assay procedures. The trap can be directly connected to an analytical argon chromatograph using the collection adapter previously described[2]. The trap design is in no way critical and the principle of total trapping may equally well be used with other carrier gases such as oxygen, carbon dioxide or steam. Even air at atmospheric pressure can be totally condensed by liquid nitrogen; the 'Drechsel' tube trap with its outlet closed will liquefy more than 200 ml./min (vapour pressure about 640 mm mercury at −196°).

IMPORTANCE OF MIXING SEQUENCE WHEN USING SET-RETARDING AGENTS WITH PORTLAND CEMENT

By G. M. BRUERE

Division of Applied Mineralogy, C.S.I.R.O. Chemical Research Laboratories, Melbourne

INITIAL experiments in an investigation of the actions of set-retarding agents in Portland cement pastes, showed that the sequence of adding these agents to pastes had large effects on setting times. These effects could account for some of the anomalous behaviour of set-retarders in concrete practice.

The set-retarding effects of various amounts of calcium ligno-sulphonate and citric acid were studied in cement pastes made with water/cement ratios of 0·35 by weight, and mixed with a propeller-type mixer at 1,000 r.p.m. Pastes were made from two commercial cements, the calculated mineral compound compositions of which are shown in Table 1. The initial and final setting times of the pastes were determined at 20° ± 1° C with a Vicat needle according to A.S.T.M. method *C*191. Pastes were mixed by the following methods: (1) Water containing a dissolved retarding agent was added to dry cement and the paste was mixed for 6 min. (2) Dry cement was pre-mixed with 90 per cent of the mixing water for 4 min, then the remaining 10 per cent, containing the retarding agent, was added and the paste was mixed for a further 2 min.

Table 1. Calculated Percentage Mineral Compositions of Cements

Mineral	Cement No. 1 Ordinary Portland cement	Cement No. 2 Low-heat Portland cement
Tricalcium silicate	51	31
Dicalcium silicate	25	43
Tricalcium aluminate	10	4
Tetracalcium aluminoferrite	7	16
Total alkali*	1·30	0·15

* Sodium oxide + 0·658 potassium oxide.

The data in Figs. 1 and 2 show that when both cements were pre-mixed with water before adding calcium ligno-sulphonate the setting times were considerably longer than when calcium ligno-sulphonate was added in the mixing water to the dry cements. In addition, differences between setting times produced by the different mixing sequences were much greater in pastes made from cement No. 1, which had a high tricalcium aluminate content, than in pastes made from the low-heat-type cement No. 2, which had a low tricalcium aluminate content. Similar differences between setting times caused by the different mixing sequences were obtained when citric acid was used as a set-retarder. However, at all concentrations, citric acid was a more powerful retarder than calcium ligno-sulphonate.

The mixing sequence effect on setting times is possibly due to competition between the gypsum in cement and

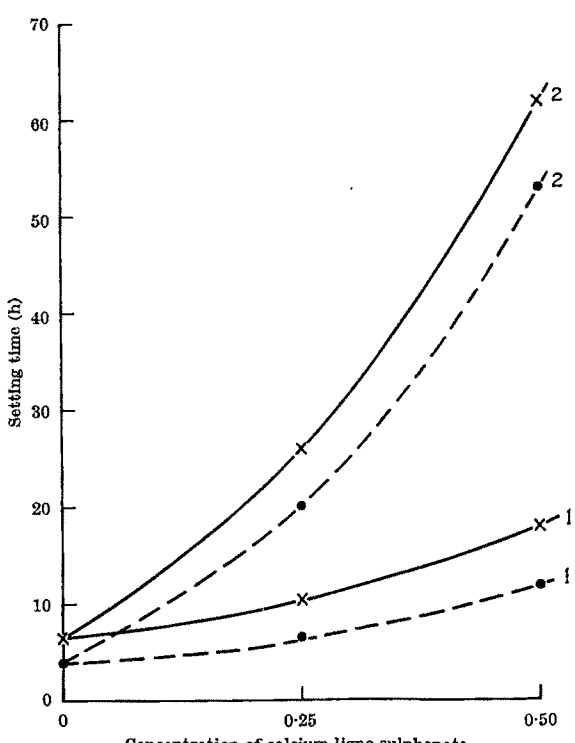

Fig. 1

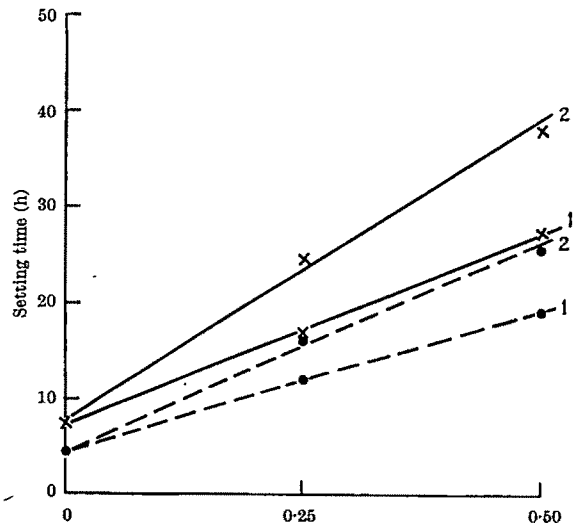

Fig. 2

Figs. 1 and 2. Setting times of Portland cement pastes containing varying concentrations of calcium ligno-sulphonate. The data in Fig. 1 were obtained with cement No. 1 and the data in Fig. 2 with cement No. 2

the organic retarder to combine with or adsorb on the tricalcium aluminate surfaces. Measurements[1] of adsorption isotherms of calcium ligno-sulphonate and salicylic acid on cement and pure cement mineral surfaces showed that tricalcium aluminate adsorbed both these organic materials much more strongly than either dicalcium or tricalcium silicate. Gypsum, which is interground with cement clinker to prevent the rapid hydration reaction of tricalcium aluminate and consequent flash setting of cement, performs this function by rapidly combining with the tricalcium aluminate surface forming calcium sulphoaluminate. When a retarder, such as calcium ligno-sulphonate or citric acid, is added directly in the mixing water to dry cement, it should adsorb on the tricalcium aluminate before any appreciable quantity of gypsum dissolves. This adsorption removes a large amount of retarder from solution and leaves only a small

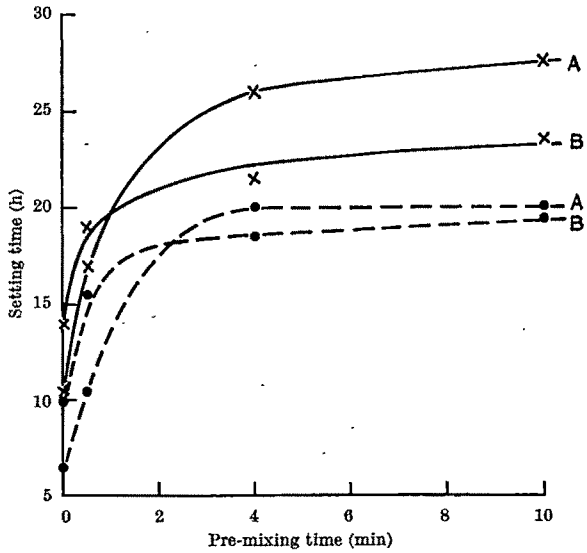

Fig. 3. Variations in setting times of Portland cement pastes with varying periods of pre-mixing before adding set-retarding agents. Cement No. 1, temperature of pastes = 20 ± 1° C, water/cement ratio = 0·35 by weight; ×, final setting time; ●, initial setting time; *A*, 0·25 per cent of calcium ligno-sulphonate by weight of cement, *B*, 0·10 per cent of citric acid by weight of cement

amount to adsorb on the silicate minerals and regard the silicate hydration reactions. In contrast to this behaviour, when cement is pre-mixed with water for a few minutes, gypsum has ample time to dissolve and coat the tricalcium aluminate. Consequently, when the retarder is added to the pre-mixed paste, the tricalcium aluminate is unable to adsorb it and a large amount of retarder is available to retard the silicate hydration reactions.

Fig. 3 shows how setting times of pastes varied with different pre-mixing periods before a retarder was added. The data demonstrate that although pre-mixing periods of 4 min were necessary to get maximum extensions of setting times, pre-mixing periods as short as 30 sec extended setting times by as much as 70 per cent.

In practice, control and prediction of setting behaviour of set-retarded concrete should be improved by specifying the time and sequence of adding water and retarding agent to cement during concrete mixing operations.

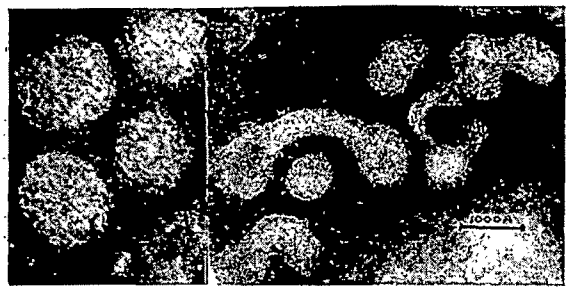
A MOLECULAR APPROACH TO TERATOGENESIS: EFFECT OF VITAMIN A ON INFLUENZA VIRUS *IN OVO*



By Dr. H. A. BLOUGH

Virus Laboratory, Department of Pathology, University of Cambridge

IN vitro studies have demonstrated that excess vitamin A may decrease the stability of lipoprotein membranes[1–3]. In a recent investigation, it was shown that vitamin A alcohol drastically altered the morphology of influenza and Newcastle disease viruses *in ovo*[4]. Since the influenza viral envelope represents a large sampling of cell membrane, the negative contrast technique[5] provides a rapid and unique method for detecting alterations in surface structure. The purpose of the work recorded here is to compare the effects of various vitamin A preparations on the integrity and shape of the viral envelope and to attempt to correlate these changes with the known teratogenic action of vitamin A (refs. 6 and 7).

The classical *PR*8 strain of influenza *A* virus was used throughout the experiments. Ten dozen 11-day-old eggs were inoculated with 100 EID_{50} of virus and incubated at 35° C. 6 h after infection, the eggs were divided into four groups and inoculated allantoically with either 150 μg, 50 μg or 5 μg of vitamin A alcohol. The remaining eggs served as viral controls. Allantoic fluids were gathered after 48 h, clarified, and infectivity and hæmagglutination assays[8] were carried out within 24 h. This experiment was repeated on consecutive weeks with all-*trans* vitamin A aldehyde, vitamin A acetate and vitamin A acid.

Virus preparations were partially purified by adsorption to and elution from human group O erythrocytes. Vitamin-treated virus was sedimented at 7,000*g* for 30 min; untreated viral controls were sedimented at 44,000*g* for 1 h. Resultant pellets were resuspended in 0·1 ml. of 1 per cent ammonium acetate, mixed with twice their

volume of 2 per cent potassium phosphotungstate (*p*H 7·0) and sprayed on to carbon-coated grids[5]. These were examined in a Siemens Elmiskop electron microscope. Particle counts, with a minimum of 500 particles, were made at random. Particles were classified as either spherical, filamentous or 'aberrant'—this latter group included all particles > 2000 Å in diameter and others the morphology of which defied description. All experiments were repeated with samples of *PR8* from the World Influenza Centre (courtesy of Dr. H. Pereira).

Untreated viral particles (Fig. 1) were similar to those described by Horne *et al.*[9]. In contrast to these, all vitamin A preparations produced marked pleomorphism (Fig. 2). Filamentous forms (Fig. 3) were most prevalent, constituting approximately 33 per cent of all specimens examined. Occasional rows of beaded particles were observed separately (Fig. 4) or arising from or within filamentous forms. Terminal bodies were occasionally seen. When virus was grown in the presence of 150 μg of (all) vitamin analogues, 'aberrant' forms (Figs. 5 and 6) accounted for 10–12 per cent of the particles. These latter particles possessed external projections and measured up to 5000 Å in diameter (or along their longest axis); with lower concentrations of vitamin, the number of these forms decreased to 5 per cent. The acetate, aldehyde, acid and alcohol were equally effective in the production of filaments and aberrant forms. However, the possibility of vitamin A acetate being hydrolysed *in ovo* to a more active form (for example, the alcohol) could not be excluded.

Some partially disrupted particles were seen with all analogues tested. In others, large portions of the viral envelope were dissolved out, revealing a tightly bound internal helix (Fig. 5). Most striking was the effect of vitamin A acid; multiple areas of the envelope were rendered electron-opaque (Fig. 6). In contrast to the effect of saponin on the Rous sarcoma virus *in vitro*[10], hexagonal arrays were not observed. Infectivity and hæmagglutination titres (Table 1) showed little change from the controls, thus suggesting that the nucleoprotein helix was unchanged.

Figs. 5 and 6. 5 (left), Large 'aberrant' particles showing dissolution of viral envelope revealing internal helix (vitamin A acetate, 5 μg) (× *c.* 68,000); 6 (right), partial dissolution of viral envelope (vitamin A acid, 150 μg) (× *c.* 98,000)

The importance of the cell surface in virus-induced congenital malformations[11], and to the localization of defects in an *in vitro* chick embryo system using antimycin-*A* (ref. 12), have been noted. Animal studies qualitating the embryopathic effect of vitamin A have shown that the neural tube, lens primordia and oral cavity are most frequently involved[6,7]. Since these latter structures are surface ectodermal ones, it is suggested that vitamin A exerts its teratogenic effect by a direct physicochemical attack on the cell membrane.

Vitamin A can act on the cellular surface in two ways. First, alterations may occur in the packing of the bimolecular lipide leaflet[13]; a linear orientation of cholesterol-phospholipide molecules would account for the production of viral filaments[4]. Secondly, because of the high degree of unsaturation of vitamin A, a sudden increase in Van der Waals' forces between lipide molecules would cause a 'separating out' of cholesterol from the leaflet[14]; this would account for defects in the envelope. Since cholesterol probably exists as an inclusion compound[15] it is unlikely that these changes are reversible *in vivo*, as has been suggested recently[16]. It would appear that the greater toxicity of the acid on the membrane is due to its larger head group (—COOH) and/or its potential ease of ionization in an *in ovo* system. Furthermore, recent experiments[17,18] have shown that the oxidation of vitamin A aldehyde to the acid is irreversible; thus suggesting that vitamin A acid may be the effective form of the vitamin.

The possibility of utilizing a viral system to elucidate alterations in membrane structure during morphogenesis may provide yet another tool for the rapid screening of potential teratogenic agents.

This investigation was supported in part by a fellowship (*EPD*-11, 468) from the National Institute of Allergy and Infectious Diseases, U.S. Public Health Service.

I thank Prof. J. D. Boyd for reviewing this manuscript.

EFFECT OF 3,4-DEHYDRO-DL-PROLINE ON GROWTH AND PROTEIN SYNTHESIS

By DR. L. FOWDEN, S. NEALE and H. TRISTRAM

Department of Botany, University College, London

AZETIDINE-2-CARBOXYLIC acid, the lower homologue of proline, acts as a potent proline analogue producing very marked growth inhibition of seedlings[1] and of *Escherichia coli*[2]. Growth inhibition was attributed to the production of abnormal protein molecules in which an extensive and stoichiometric replacement of proline residues by azetidine-2-carboxylic acid had occurred. Pipecolic acid, the higher proline homologue, showed no growth inhibitory effect and was not incorporated into cell protein.

Recently, 3,4-dehydro-DL-proline was shown to produce strong inhibition of growth of several micro-organisms[3]. This inhibition could be reversed by an exogenous supply of proline. No attempt was made to show whether the compound was incorporated into microbial protein. Other biological effects of 3,4-dehydroproline have been demonstrated (cited in ref. 4). The experiments described here show that 3,4-dehydro-DL-proline is incorporated into both higher plant and bacterial protein, replacing an approximately equimolar amount of proline. The effect of this incorporation on the rate of bacterial protein and enzyme synthesis was also determined.

Mung bean seeds were supplied with various amounts of 3,4-dehydro-DL-proline dissolved in water imbibed during 18 h at 26°. The seedlings were then transferred to moistened vermiculite and grown for further periods in the dark[1]. Radicles were detached from batches of collected seedlings (usually 50), and their combined fresh weights used as the index of growth. Proline was supplied together with dehydroproline in the water of imbibition in experiments designed to investigate the reversal of analogue inhibition.

*E. coli C*4 (ref. 5) was grown in a glucose/mineral salts medium[6] in shake-cultures at 37°. This strain forms an inducible β-galactosidase and carries a mutation rendering the formation of alkaline phosphatase insensitive to repression by orthophosphate. In experiments in which induced β-galactosidase formation was measured glucose was replaced by 0·5 per cent maltose and 10^{-3} M methyl-β-D-thiogalactoside added as inducer. Growth was determined by optical density measurement. 3,4-Dehydro-DL-proline was added to exponentially growing cultures (when cell density reached 35 μg dry weight/ml.) at concentrations indicated in the text. Incorporation of amino-acids labelled with carbon-14 into the trichloroacetic acid (TCA)-insoluble fraction and alkaline phosphatase and β-galactosidase levels in *E. coli* were determined as described by Neale and Tristram[8].

In order to extract protein, radicles were macerated in 1 per cent sodium borate solution (*p*H *c.* 9), centrifuged at 25,000*g* (15 min) and a protein fraction precipitated from the supernatant by adjustment to *p*H 4·5 with acetic acid, followed by warming at 60° for 10 min. This protein fraction was twice extracted with 5 per cent TCA (15 min at 90°), twice with 75 per cent ethanol (15 min at 80°), and then successively with ethanol, acetone and ether. Protein of *E. coli* cells was obtained by the procedure described by Roberts *et al.*[7]. The insoluble fraction finally obtained consists of most of the cell protein, together with cell wall material, and is referred to as the 'principal protein fraction'.

Protein fractions were hydrolysed with 6 N hydrochloric acid at 100° for 24 h. Paper chromatography was used to establish the presence of dehydroproline in the hydrolysates. A specific method for identifying the analogue has been developed. Chromatograms were first treated with 0·2 per cent isatin in acetone to reveal the proline spots (dehydroproline gave no colour at this stage); they were then oversprayed with Ehrlich's reagent when the blue spots of proline were rapidly decolorized and dehydroproline spots became an intense pink colour. Less than 0·5 μg dehydroproline could be detected on one-dimensional chromatograms run in butan-1-ol–acetic acid–water (90 : 10 : 29, by vol.) when the analogue moved slightly slower than proline. For analysis, portions of hydrolysates were chromatographed together with a series of known amounts of proline and dehydroproline; an estimate of the proline and dehydroproline content of the hydrolysate could be made after colour development as here.

Incorporation of dehydroproline into seedling protein. Dehydroproline produced a marked growth inhibition of mung bean seedlings although quantitatively it was less effective than azetidine-2-carboxylic acid at similar concentrations (Fig. 1). The growth inhibition caused by providing 4 mg dehydro-DL-proline to 50 seeds was reversed when 8 mg (or more) L-proline were supplied simultaneously. The possibility that dehydroproline became incorporated into protein was examined using radicles detached from seedlings grown for total periods of 24, 48 and 72 h. Dehydroproline could be detected in protein isolated from each type of radicle. However, the number of proline residues replaced in the protein by the analogue decreased as the age of the radicle increased and represented 12–15, 6–8, and 3–5 per cent of the total prolines for 1-, 2-, and 3-day radicles respectively. The growth rate of the radicles in the presence of L-azetidine-2-carboxylic acid or dehydroproline is recorded in Table 1. L-Azetidine-2-carboxylic acid supplied at a level of 3 mg/50 seeds allowed slight initial growth but soon proved lethal. In contrast, after an early initial inhibition had been overcome, it is probable that growth in the presence

Table 1. Rate of Growth of Single Radicles of *Phaseolus aureus* (Mung Bean) Radicles in the Presence of L-Azetidine-2-Carboxylic Acid and 3,4-Dehydro-DL-Proline

Analogue	mg/50 seeds	Radicle fresh weights Day 1 g	Day 1 $\log_{10}$g	Day 2 g	Day 2 $\log_{10}$g	Day 3 g	Day 3 $\log_{10}$g
None	—	0·68	−0·17	1·46	0·16	2·95	0·47
L-azetidine-2-carboxylic acid	3	0·21	−0·68	0·22	−0·66	0·23	−0·64
3,4-dehydro-DL-proline	6	0·31	−0·51	0·58	−0·24	1·14	0·06

of the same amount of the L-form of dehydroproline became logarithmic, as in control seeds.

Effect of dehydroproline on growth and protein synthesis in E. coli. When added to exponentially growing cultures of *E. coli* dehydroproline (20 or 50 μg/ml.) caused severe inhibition of growth. After a short initial period, during which increase in optical density occurred at a rate only slightly lower than that of a control culture, growth became 'linear'. The linear increase continued at a constant rate for about 3 h and then at a slightly diminished rate for at least a further 3 h. Exposure to 5 μg dehydroproline/ml. still resulted in 'linear' growth but after about 2·5 h the culture partially escaped from inhibition, growth becoming exponential, though at a somewhat lower rate than that found in control cultures (Fig. 2). Microscopic examination of stained smears revealed that the average length of cells exposed to dehydroproline was 2–3 times that of control cells.

Dehydroproline (25 μg/ml.) was added to cultures growing exponentially in 15 ml. basal medium supplemented with L-[U-^{14}C]-arginine (3 μmoles; 0·8 μc./μmole). At suitable intervals incorporation of radioactivity into TCA-insoluble material and increases in optical density were measured. Growth and incorporation of radioactivity were also followed in appropriate control flasks without analogue. The results are presented in Fig. 3 and demonstrate that the differential rate of incorporation of arginine into the TCA-insoluble fraction is unaffected by growth in the presence of dehydroproline. Similar results were obtained when basal medium was supplemented with L-[U-^{14}C]-phenylalanine or L-[2-ring-^{14}C]-histidine.

Dehydroproline (3 mg) was added to an exponentially growing culture of *E. coli* (final volume 120 ml.). During the subsequent growth period the optical density of the culture increased linearly from 0·075 to 0·200 in 5·5 h. At the end of the growth period the culture was rapidly cooled and the 'principal protein fraction' isolated as already described. A similar fraction was isolated from a control culture. The 'principal protein fraction' from control cells contained 20–25 μg proline/mg, while that from treated cells contained 8–9 μg proline and 12–14 μg dehydroproline/mg. The analogue accounted for about 60 per cent of the total imino-acid residues present in protein and therefore must have almost completely replaced proline in those protein molecules synthesized after addition of analogue.

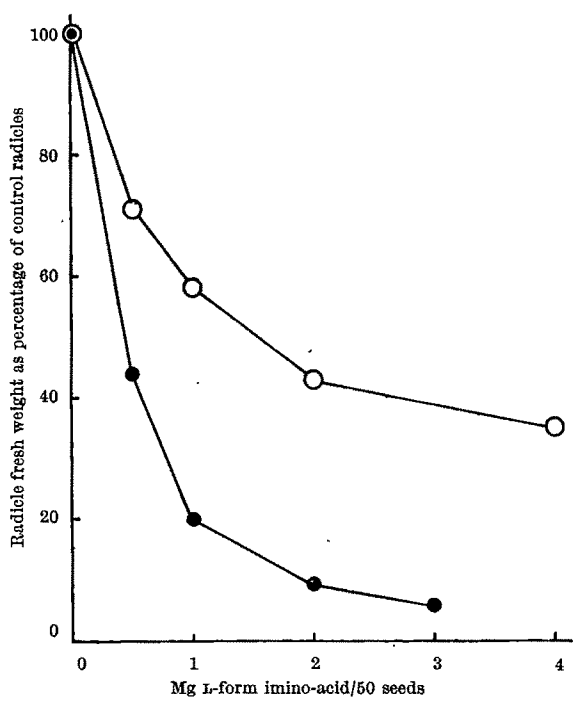

Fig. 1. Fresh weight yield of mung bean radicles after 3 days' growth in the presence of L-azetidine-2-carboxylic acid (●) and 3,4-dehydro-DL-proline (○)

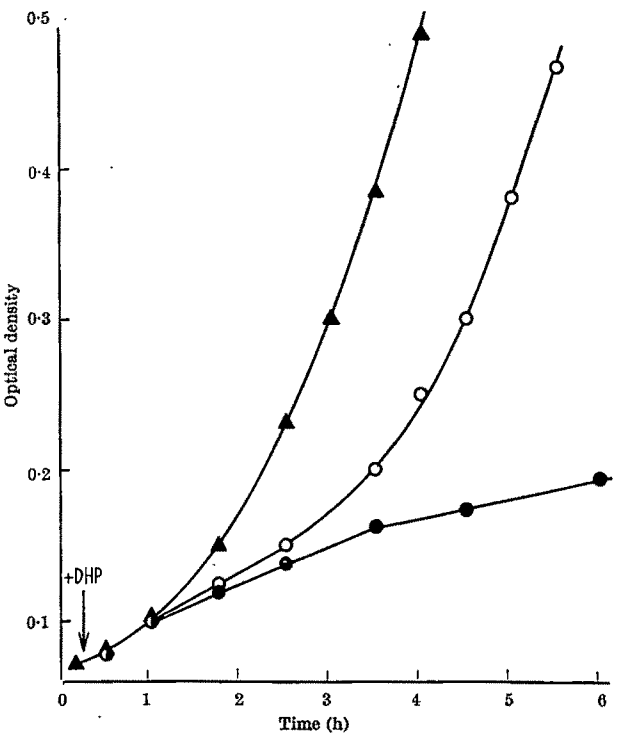

Fig. 2. Growth of *E. coli* in the presence of varying concentrations of 3,4-dehydro-DL-proline. Analogue was added to exponentially growing cultures at the point indicated (+ DHP). Control (▲); plus analogue, 5 μg/ml. (○); 20 μg/ml. or 50 μg/ml. (●)

Synthesis of alkaline phosphatase and β-galactosidase in E. coli. The production of alkaline phosphatase and induced β-galactosidase was compared in normal cells and cells growing in the presence of dehydroproline. The differential rate of synthesis of both enzymes in control cultures remained constant throughout the experiment (Fig. 4*a* and *b*). The presence of dehydroproline (20 or 50 μg/ml.) completely prevented the appearance of β-galactosidase activity. Dehydroproline (5 μg/ml.) also initially prevented β-galactosidase synthesis, but enzyme activity developed later, the differential rate of synthesis being identical with that in control cultures (Fig. 4*a*). The production of active β-galactosidase coincided with the increase in growth rate already noted (Fig. 2).

The differential rate of synthesis of alkaline phosphatase was also affected by the presence of dehydroproline (25 μg/ml.). Initially it remained comparable with that observed in the control culture, but later the differential rate of synthesis of active enzyme decreased. Although the change in rate was not great it was reproducible in a series of experiments (Fig. 4*b*).

Discussion

The initial level of dehydroproline incorporation, although restricting early growth of mung bean seedlings by the production of biologically ineffective protein molecules, apparently did not prevent limited hydrolysis of reserve seed protein. Therefore the amount of free

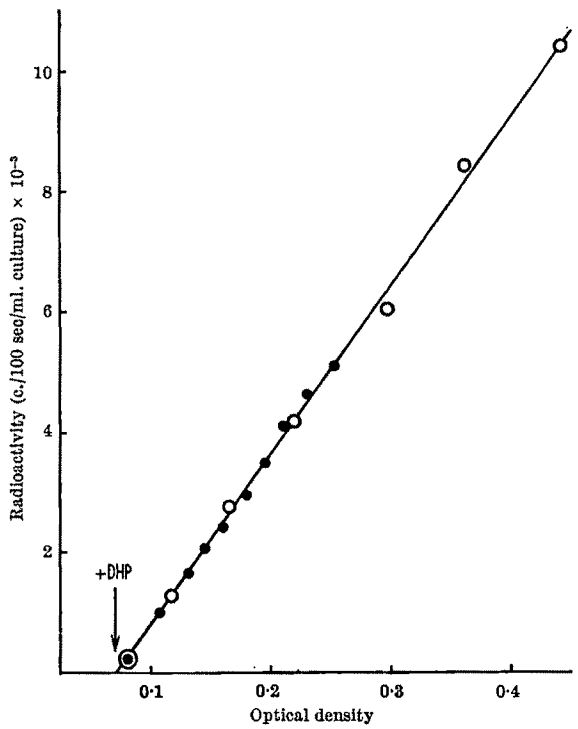

Fig. 3. Incorporation of radioactive arginine into the TCA-insoluble fraction of *E. coli*. 3,4-Dehydro-DL-proline (25 μg/ml.), where required, was added to exponentially growing cultures, as indicated by the arrow (+DHP). Flasks contained 15 ml. basal medium +L-[U-^{14}C]-arginine (3 μmoles; 0·8 μc./μmole). Control (○); plus dehydroproline (●)

proline in the seedlings would increase gradually and eventually would be sufficient to exclude effectively any further incorporation of the analogue into proteins of growing radicles. This stage may be reached at about 48 h, after which the increase in the value of $\log_{10}$ (radicle fresh weight) was about the same for the control and dehydroproline-treated seedlings.

The growth response of *E. coli* to the presence of dehydroproline resembled closely that caused by other amino-acid analogues known to be incorporated into protein (for review, see ref. 9). During the first 45–60 min exposure to analogue growth inhibition was slight, suggesting that the cells at first produced sufficient proline to compete with analogue for incorporation into protein, but that the levels of available proline afterwards decreased, so allowing greater incorporation of dehydroproline, accompanied by 'linear' growth. This behaviour is consistent with the view that dehydroproline repressed enzymes involved in proline synthesis. That amino-acid analogues can 'mimic' naturally occurring amino-acids in operating repression mechanisms leading to cessation of formation of biosynthetic enzymes has been demonstrated in other systems[10,11]. The possible repression of proline biosynthetic enzymes has not been investigated in detail, but a proline-dependent *E. coli* mutant accumulated Δ^1-pyrroline-5-carboxylic acid, an intermediate in the conversion of glutamate to proline, when grown in proline-limiting medium but not when grown in proline-rich medium[12].

This observation could be interpreted as repression of proline biosynthetic enzymes by proline, and although Strecker[12] demonstrated inhibition of Δ^1-pyrroline-5-carboxylic acid formation as a result of end-product inhibition by proline the possibility of partial repression of proline biosynthetic enzymes was not excluded.

Using the value reported by Roberts *et al.*[7] for the weight of proline/g dry weight *E. coli* cells it was calculated that the recovery from growth inhibition observed in cultures exposed to 5 μg dehydroproline/ml. (Fig. 2) was not due to exhaustion of analogue as a result of complete incorporation into protein. Escape from growth inhibition in the presence of low concentrations of dehydroproline could be explained by metabolic conversion of the analogue to a non-toxic compound, though there is no evidence for such a conversion. Alternatively, if dehydroproline repressed proline biosynthetic enzymes, the fall in dehydroproline concentration due to incorporation of some of the analogue into protein could lead to dehydroproline levels no longer effective in repression. Proline biosynthesis would then recommence, leading to proline concentrations sufficient to compete with the analogue and prevent its further incorporation into protein.

Incorporation of either arginine, phenylalanine or histidine occurred at the same differential rate in both control and dehydroproline-treated *E. coli* cells, indicating the continued synthesis of protein in the presence of the analogue. A high level of replacement of proline by dehydroproline residues in protein was attained and was accompanied by failure to produce active β-galactosidase. Earlier workers[13,14] have concluded that such observations are consistent with the view that enzymatically inactive proteins may be formed as a result of replacement of naturally occurring amino-acids by appropriate structural analogues. However, it has been demonstrated[15] that β-galactosidase formation by a 'regulator-constitutive' (*i*⁻) *E. coli* strain could be reduced by growth under conditions leading to accumulation of metabolic intermediates, and it has been suggested[9] that this mechanism may operate under conditions of low growth rates, as observed during exposure to amino-acid analogues. The possibility that formation of a β-galactosidase-like protein occurs in the presence of dehydroproline is under investigation. In *E. coli C*4 the synthesis of active induced β-galactosidase was prevented even when growth was little affected. It has been suggested[16] that induction involves the antagonism

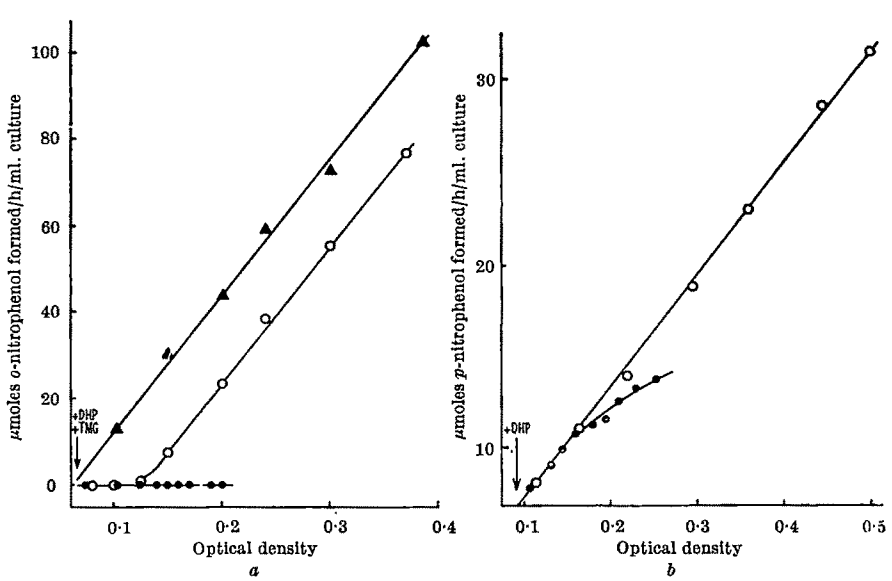

Fig. 4. Differential rate of synthesis of (*a*) β-galactosidase and (*b*) alkaline phosphatase in the presence of 3,4-dehydro-DL-proline. Arrows indicate the point of addition of analogue (+DHP) and, in (*a*), 10^{-2} M methyl-β-D-thiogalactoside (+TMG). (*a*) β-Galactosidase: control (▲); plus dehydroproline, 5 μg/ml. (○); 20 μg/ml. or 50 μg/ml. (●); (*b*) alkaline phosphatase: control (○); plus dehydroproline (25 μg/ml.) (●)

by the inducer, of a repressor formed by the relevant regulator gene. If, as appears likely, the repressor is protein[17], minor modification resulting from incorporation of very small amounts of dehydroproline might render it incapable of combination with the inducer. This explanation is unlikely since formation of active β-galactosidase is also stopped abruptly by addition of dehydroproline (25 μg/ml.) to exponentially growing cultures of 'regulator-constitutive' (i^-) and 'operator-constitutive' (o^c) strains of *E. coli*[18]. In both these strains, since production of β-galactosidase is not dependent on the presence of a functional repressor, even if the repressor were affected by dehydroproline, synthesis of the enzyme might be expected to continue at least during the period when growth was scarcely affected (cf. alkaline phosphatase).

Synthesis of alkaline phosphatase differed from that of β-galactosidase in that the differential rate of formation was at first identical with that of control cells, but later decreased. Since, at identical analogue-levels, the differential rates of incorporation of several labelled amino-acids remained constant, it seems likely that the fall in the differential rate of formation of active alkaline phosphatase coincided with the production of enzymatically impaired protein due to the incorporation of progressively increasing amounts of dehydroproline towards the end of the experiment.

We thank Dr. B. Witkop of the National Institutes of Health, Bethesda, Maryland, for a gift of dehydroproline, and Dr. A. Garen of the Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts, for a culture of the bacterial strain used. One of us (S. N,) thanks the University of London for the award of a Keddey Fletcher–Warr studentship.

ACTION SPECTRUM OF MITOTIC FERROUS COMPLEX

By Dr. J. E. AMOORE

Department of Zoology, University of California, Berkeley

"UNKNOWN mitotic ferrous complex" was my provisional name for an endogenous iron compound which I deduced must exist in root tips, and which seems to be an indispensable participant in the mitotic process[1]. My chain of reasoning was as follows. Cell divisions actually in progress in pea root tips can be arrested by oxygen lack or cyanide poisoning[2]. It would be natural to assume that the arrest occurred because of the stoppage of respiration through cytochrome oxidase. However, quantitative measurements of the rates of mitosis and respiration as functions of oxygen tension showed that a far higher degree of anaerobiosis was required to arrest mitosis than sufficed to stop respiration[3,4]. Hence not cytochrome oxidase but some other component of the cell must be responsible for the stoppage of mitosis. Now the fact that both oxygen lack and cyanide inhibit mitosis suggests that a heavy metal is involved. If the heavy metal should happen to be iron, then it would be expected that carbon monoxide would also be capable of arresting mitosis (in the dark), and that the inhibition would be relieved by illumination[5,6,21]. Both these predictions were fulfilled by experiment[1], which provides very strong evidence that an iron compound is indeed responsible for the arrest of mitosis. Further tests showed that the inhibition of mitosis by hydrogen cyanide was also reversed by light[1] (experiment based on ref. 7), which indicates that the iron compound remains always in the divalent state. Hence the responsible component was referred to as the 'mitotic ferrous complex' (MFC).

It will be recalled that this chain of reasoning lies closely parallel to that of Warburg[6] in his celebrated series of investigations leading to the recognition of the *Atmungsferment*, now known as cytochrome oxidase. That being so, it was considered desirable to pursue the analogy one step further, and try the efficacy of light of different wave-lengths in reversing the inhibition of mitosis by carbon monoxide. This procedure enabled Warburg *et al.*[8] to plot the relative photochemical absorption spectrum ('action spectrum') of the respiratory pigment, which was not identified or isolated until many years later. In the hope that history might repeat itself, I was encouraged to embark on what is technically rather an exacting series of experiments. However, in order to find out which parts of the spectrum would later repay the most detailed investigation, the whole visible spectrum was first surveyed in a single preliminary experiment. The results of this experiment showed so clearly that the MFC is a ferroporphyrin, that it was felt to be of interest to report the results at this stage.

Under selected conditions, the rate of mitosis may be calculated from the mitotic index (M.I.) observed at a known time after excising the root tips from the seedlings[4]. The largest difference in M.I. between darkness and (white) light was observed[1] in 10 per cent carbon monoxide, 20 per cent oxygen and 70 per cent nitrogen, so this gas mixture was chosen for the present purpose. The experimental cell was constructed from a Beckman silica cuvette of 1-cm light path (Fig. 1). The 2-mm long root tips (*Pisum sativum*, var. Alaska, 2-day seedlings) were placed on a 3 cm × 1 cm glass slide in pairs, with their cut surfaces in contact, so as to form a continuous double file of 20 pairs, covering a length of 20 mm. A spectrum 20 mm wide from red edge to violet edge would be projected on to the root tips, so that each pair of tips would be exposed to radiation of different wave-length, and between them they would cover the whole visible spectrum. The invisible extremes of the spectrum were masked out, and two sets of 3 tips were placed near the ends of the slide, to serve as controls in 10 per cent carbon monoxide in darkness. The tips were moistened with about 0·03 ml. of water, and the slide was inserted in the cuvette. A cup containing 0·05 ml. N potassium hydroxide was included to absorb carbon dioxide, and the cuvette was closed by a square gum-rubber stopper pierced with two 20-gauge hypodermic needles. The moist gas mixture (150 ml.) was flushed through the cell at the start of the experiment, and a further 50 ml. was passed each hour thereafter to replace the oxygen consumed by respiration.

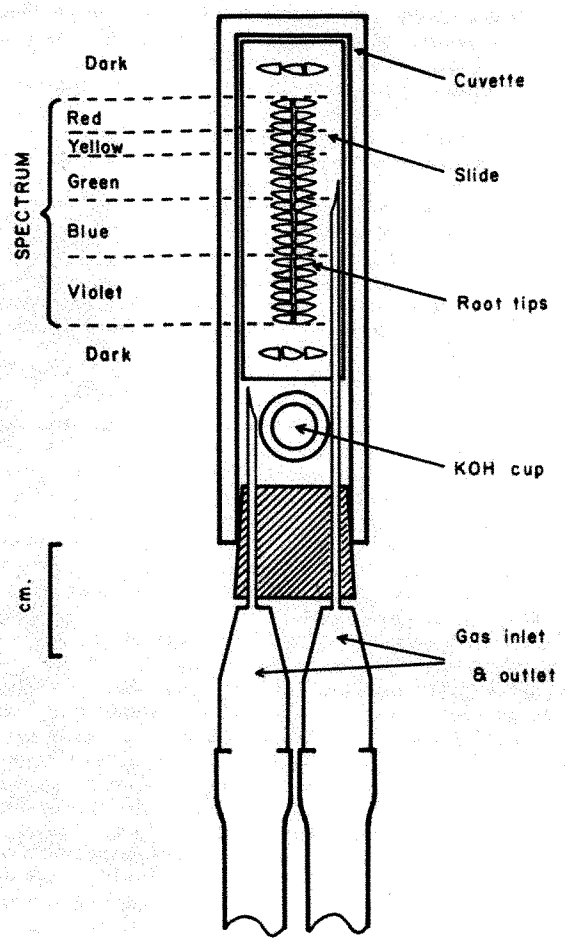

Fig. 1. Experimental cell for illuminating root tips with light of different wave-lengths, under controlled atmosphere

The cuvette was placed in a Beckman cell holder laid flat on a piece of black velvet, and clamped in position.

I thank Prof. J. E. Gullberg of this Department for kindly setting up the optical and electrical equipment necessary for projecting the spectrum, determining the wave-length and measuring the light intensity. The light source was an upright, 21-W straight filament incandescent lamp. The light passed horizontally through an aspheric lens and a large triangular flint-glass prism laid flat, being finally reflected vertically downwards in focus on to the root tips by a surface aluminized mirror. The whole apparatus was set up in a darkroom at 23° C. At the end of the experiment the exact positions of the root tips relative to the red end of the spectrum were found by placing the glass slide on a 1 cm wide strip of mm ruled co-ordinate paper. This paper was later placed in the cuvette *in situ*, and the distribution of wave-length along the cuvette was plotted by inserting in turn in the light path a series of 33 narrow-band interference filters of known maximum transmission wave-length, and noting the position of the transmission band on the co-ordinate paper. The distribution of light intensity through the spectrum was determined with a windowless Moll-type linear thermopile (1 mm slit width) which was moved by millimetre increments through the spectrum at a position equivalent to that of the root tips. The galvanometer deflexions were converted to absolute units (μcal/cm²/sec) by calibration with a radiation standard lamp.

A time of 65 min elapsed between excising the root tips and getting them in place in the cuvette. They were exposed to 10 per cent carbon monoxide in the spectrum for 230 min; and a further 20 min had passed by the time the root tips had been removed (in pairs) and fixed in separate vials of acetic alcohol. The M.I. was counted for each pair of tips, and converted by means of a calibration curve derived from previous experiments[3,4] into amount of mitotic progress. The mitotic progress made by root tips while exposed to 10 per cent carbon monoxide was expressed as a percentage of the mitotic progress made by root tips exposed to air for the same period. This percentage represents the 'relative rate of mitosis', that is, the average rate of progress of cells through the visible phases of mitosis[4].

The results are shown in Fig. 2. The upper broken line represents the rate of mitosis in air (100 per cent), and the lower broken line shows the effect of 10 per cent carbon monoxide in darkness, which decreased the relative rate of mitosis to 58 per cent of normal. The upper curve demonstrates clearly that only certain regions of the spectrum were effective in preventing the inhibition of mitosis by carbon monoxide. Light in the blue-violet and in the yellow-orange regions completely removed the inhibitory effect of carbon monoxide. In fact, a slight stimulation of the rate of mitosis was revealed. The most effective wave-lengths were 436–466 mμ and 578–612 mμ. (There was also possibly a minor peak in the blue-green at 510–525 mμ, but the height of this peak was close to the counting error in determining the M.I.) The lower curve shows the steep fall in light intensity from the red towards the violet, on account of the nature of grey-body radiation from the filament, and the greater dispersion by the prism in the violet. It is notable that although the blue light had only about one-tenth the intensity of the yellow, yet it was just as effective in reversing the inhibition by carbon monoxide.

Insufficient data are yet available to convert these results into a complete photochemical absorption spectrum according to Warburg's procedure[5]. Nevertheless, the form of this simple action spectrum (Fig. 2) allows some important conclusions to be reached. The spectrum is definitely that of a (carboxy-) ferroporphyrin, with its

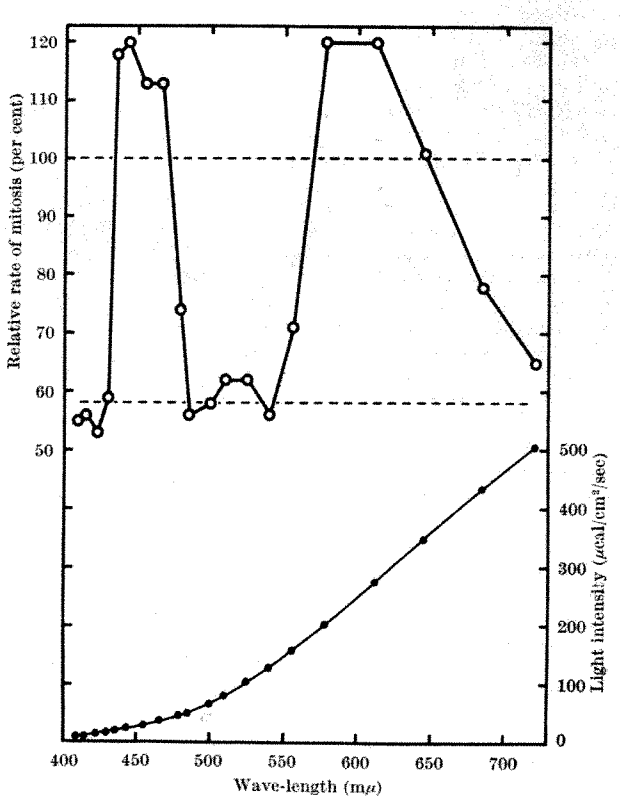

Fig. 2. Action spectrum of the mitotic ferrous complex (MFC, or mitohæm), in 10 per cent carbon monoxide. The upper curve shows the relative rates of mitosis at each wave-length, and the lower curve the corresponding light intensities

Soret or γ-band in the violet and its α-band in the yellow. The roughly 10 times stronger absorption in the violet compared with the yellow is in keeping with this conclusion. One may even follow Warburg's argument[9] a little further; the γ-band is at too long a wave-length for it to be a red hæmin, whereas the α-band is at too short a wave-length for it to be a green hæmin. In fact the positions of the absorption bands suggest that the MFC belongs to the class of red/green hæmins, or phæohæmins. The phæohæmins include Warburg's *Atmungsferment* or cytochrome oxidase, the invertebrate respiratory carrier chloroeruorin, and the disputed 'Pasteur enzyme' of Stern and Melnick[10].

From quantitative measurements of the relative affinities of MFC for oxygen, carbon monoxide and hydrogen cyanide, I had earlier concluded that the MFC must be very closely analogous to *Gastrophilus* hæmoglobin and to the reduced form of cytochrome oxidase[1]. The absorption spectra of *Gastrophilus* hæmoglobin[11] suggest, however, that it is a red hæmin rather than a phæohæmin. The relative affinity of chlorocruorin[12] for carbon monoxide and oxygen is completely different from that of the MFC. Hence, among the known naturally-occurring ferrohæmoproteins, only cytochrome oxidase (cytochrome a_3) and the Pasteur enzyme remain as close relatives of the MFC. Functionally the MFC is distinct from both, because it is involved with mitosis, whereas cytochrome a_3 is concerned with respiration and the Pasteur enzyme perhaps controls glycolysis. In its detailed properties MFC is distinct from cytochrome a_3 because with oxygen the latter undergoes autoxidation to the ferric state (at least in the presence of cytochrome *c*, ref. 13), whereas the MFC becomes oxygenated rather than oxidized. Also cytochrome oxidase differs from the MFC in the relationship of the partition constant to the CO/O_2 ratio, for the partition constant for cytochrome a_3 depends on the simple ratio (CO/O_2), whereas that for the MFC requires the fourth root thereof $(CO/O_2)^{0.25}$. The Pasteur enzyme has not been characterized in enough detail for it to be possible to decide which of the two, cytochrome a_3 or MFC, it resembles the most.

The function and properties of the MFC seem to be sufficiently distinct and definite to qualify it for a separate name. From its demonstrated involvement in *mito*sis, and its characterization as a ferro*hæmo*protein, I suggest that the MFC be called *mitohæm*.

The discovery of mitohæm, and the consideration that cytochrome a_3, Pasteur enzyme and mitohæm may all co-exist in dividing cells, seem to call for some general comments on their interrelationships. Their chemical properties, particularly their susceptibilities to inhibitors, are so similar that it is experimentally rather difficult to distinguish between them and their respective functions. There are in fact long histories of controversy, both as to whether the Pasteur effect is due to respiratory inhibition[14], and as to whether the arrest of mitosis is caused by stoppage of respiration[1,15]. There is evidence that the order of susceptibility of the three hæmoproteins to the same inhibitor may vary from one tissue to another; for example, the Pasteur enzyme is more sensitive than respiration to oxygen lack in retina, chorion and sarcoma, and less sensitive in nucleated blood cells[16]. Such variability may help to account for the recent finding of Epel[17] that mitotic arrest in sea urchin eggs by oxygen-lack, carbon monoxide or hydrogen cyanide is actually caused by the fall in adenosine triphosphate (ATP) content due to respiratory inhibition, whereas carbon monoxide failed to exhibit any selective effect on MFC; and my opposite finding[18] that the arrest of mitosis in pea roots by these inhibitors is quite independent of ATP-level, but is brought about through the MFC.

I have shown that carbon monoxide can lead to stimulations of both mitosis and respiration, provided its inhibitory effects on the iron-containing systems are overcome by strong light, and I suggested that some other heavy metal, not iron, must be involved in mediating the stimulation[1]. The known occurrence of copper, of indefinite function, in cytochrome oxidase[19], suggests the possibility that it may act as a regulator of the activity of the cytochrome oxidase. If copper should also be associated with the closely related mitohæm, it could explain the stimulating effect of carbon monoxide in the light on mitosis.

There is recent evidence from microspectrophotometric investigations that a hæm pigment is present in the chromosomal regions of mature erythrocyte nuclei in the newt, and it is suggested that it may play some part in maintaining the condensed state of the chromosomes[20]. A possible concordance between these results and mitohæm suggests itself.

It must be emphasized that mitohæm represents an important, vulnerable participant in the mitotic cycle. Following its chemical identification, it should prove possible to devise selective co-ordinating agents which will combine with and inactivate the ferrous atom of mitohæm, without affecting the Pasteur enzyme or cytochrome oxidase. For example, carbon monoxide itself demonstrates the possibility[1,21], and ethylisocyanide may be a further step in the right direction. Ethylisocyanide selectively inhibits the Pasteur effect without affecting respiration[22], and it is also a very potent inhibitor of mitosis[23]. This last observation prompts the thought that some other known mitotic inhibitors may actually bring about their effect by inactivating mitohæm.

Considering the close relationship among cytochrome oxidase, Pasteur enzyme and mitohæm it seems appropriate to mention Warburg's belief that cancer cells are those which have reverted from respiration to fermentation[24]; in other words, that their Pasteur effect is out of control. Remembering that cancer cells are almost by definition those in which mitosis is out of control, it may be suggested that the cancerous condition is associated with a reciprocal imbalance among the normal activities of cytochrome a_3, Pasteur enzyme and mitohæm. In any event, it is clear that the complex relationships among these three phæohæmoproteins will amply repay the most detailed investigation.

I have already thanked Prof. J. E. Gullberg for his help. I also thank Prof. D. Mazia for the hospitality of his Laboratory. The work was carried out while I was a Fellow of the Jane Coffin Childs Memorial Fund for Medical Research.

ACETYLCHOLINESTERASE ACTIVITY OF CAPILLARY BLOOD VESSELS IN THE CENTRAL NERVOUS SYSTEM OF THE RABBIT

By Lieut.-Colonel J. C. CROOK, R.A.M.C.
Chemical Defence Experimental Establishment, Porton Down, Salisbury, Wilts.

DURING an investigation into the localization of acetylcholinesterase in the rabbit's central nervous system (to be published) it was noted that capillaries giving a positive reaction to acetylcholinesterase histochemical staining were present in some areas of the brain.

After being killed by intravenous 'Nembutal', normal rabbits were perfused via the aorta with saline followed by neutral formalin for 3 h, after which the brain and medulla were removed and placed in cold buffered formalin overnight (4° C). Frozen sections 40μ thick were then treated by Shute and Lewis's[1] modification of the Koelle[2] technique using acetylthiocholine iodide as substrate.

To confirm that the esterase present in capillaries was acetylcholinesterase, butyrylthiocholine iodide, which is hydrolysed by cholinesterase but not by acetylcholinesterase, was used as a substrate on a number of sections. Also in another series of controls using acetylthiocholine iodide as the substrate the specific acetylcholinesterase

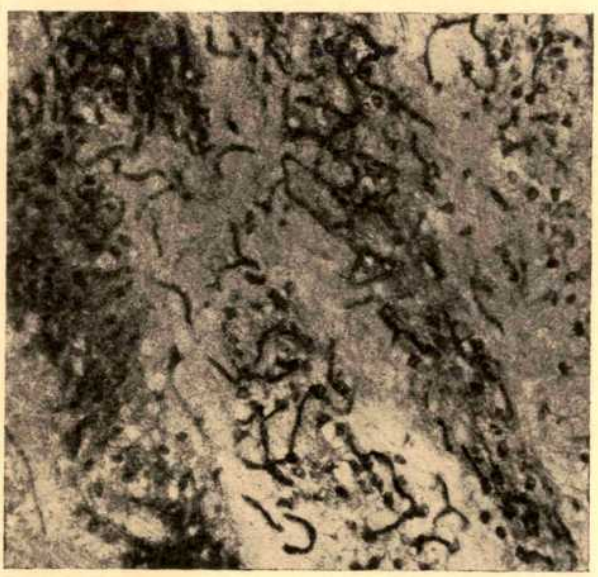

Fig. 1. Medulla. Olive: acetylcholinesterase-positive capillaries (× 75)

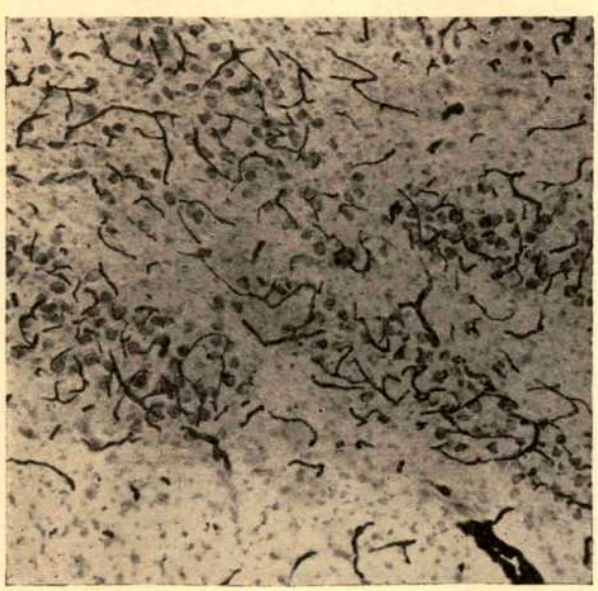

Fig. 2. Medulla. Olive: indian ink-filled capillaries (× 75)

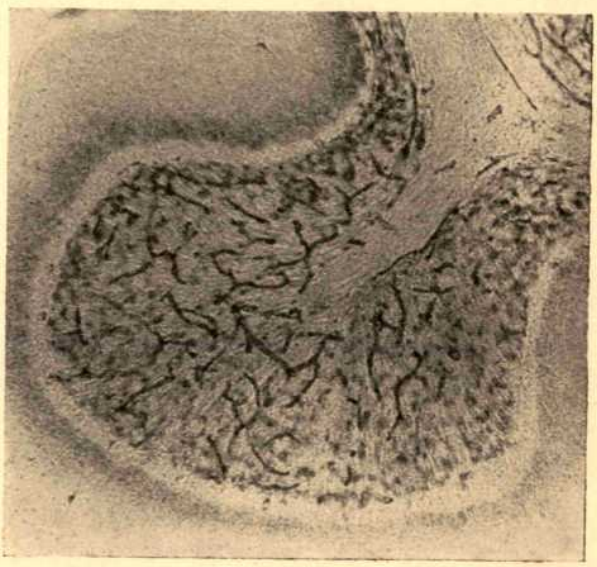

Fig. 3. Cerebellum. Acetylcholinesterase-positive capillaries in granular layer only (× *c.* 66)

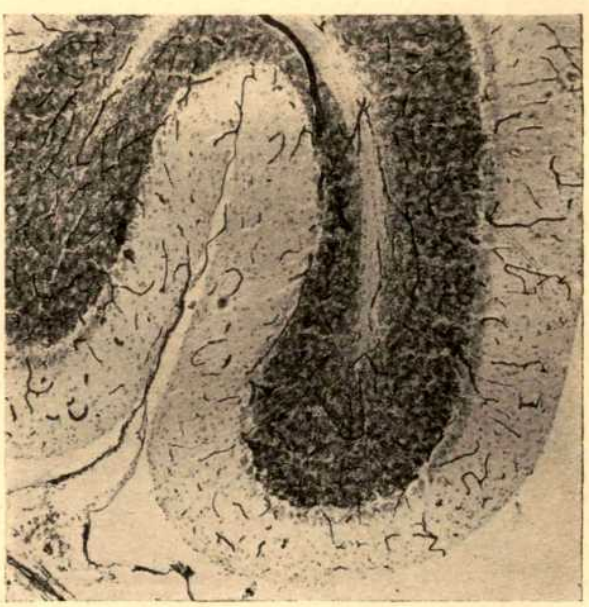

Fig. 4. Cerebellum. Indian ink-filled capillaries present in all layers (× 60)

inhibitor 62 *C*47 was added. These two control series gave consistently negative results.

As an indication that the structures concerned actually were capillary blood vessels, the general picture presented was compared with that provided by indian ink perfusion.

In all about 25 rabbits were used for the enzyme preparations and two for the indian ink perfusion.

Although the indian ink preparations showed that small capillaries were abundant throughout the central nervous system with an increase in density in grey matter relative to white, the acetylcholinesterase-positive capillaries were limited in their distribution and appeared to be present in the following areas only:

(*A*) *Medulla.* (1) Olive (Figs. 1 and 2); (2) a small area of the nucleus of the spinal tract of the V nerve; (3) vestibular nucleus.

In addition weakly positive acetylcholinesterase-positive capillaries were often found lateral to the X nerve nucleus and in the reticular formation, particularly around the lateral nucleus.

(*B*) *Cerebellum* (Figs. 3 and 4). Acetylcholinesterase-positive capillaries were abundantly present in the granular layer yet absent in the molecular and Purkinje cell layers. Indian ink preparations showed that capillaries were present almost equally in all layers with perhaps a slight preponderance in the granular layer.

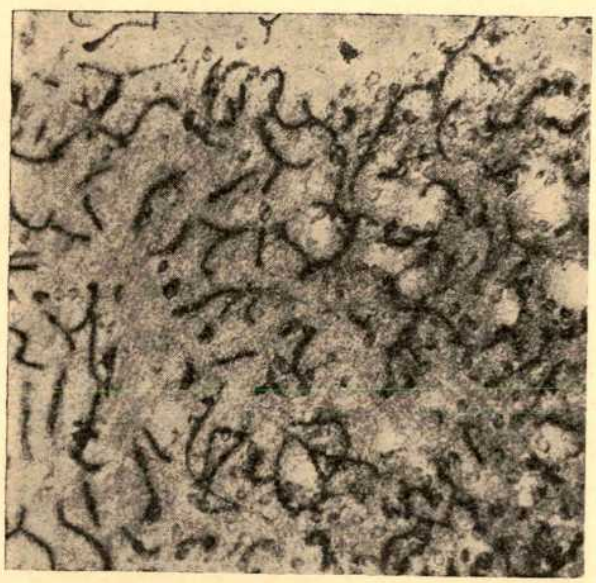

Fig. 5. Thalamus. Acetylcholinesterase-positive capillaries (× 75)

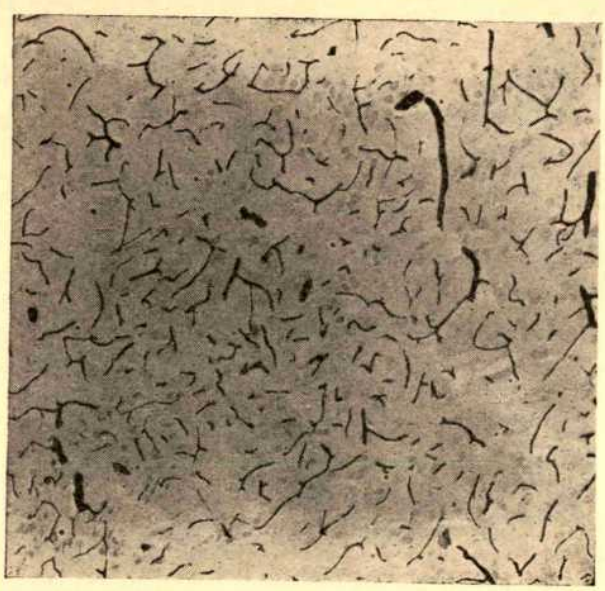

Fig. 6. Thalamus. Indian ink-filled capillaries (× 75)

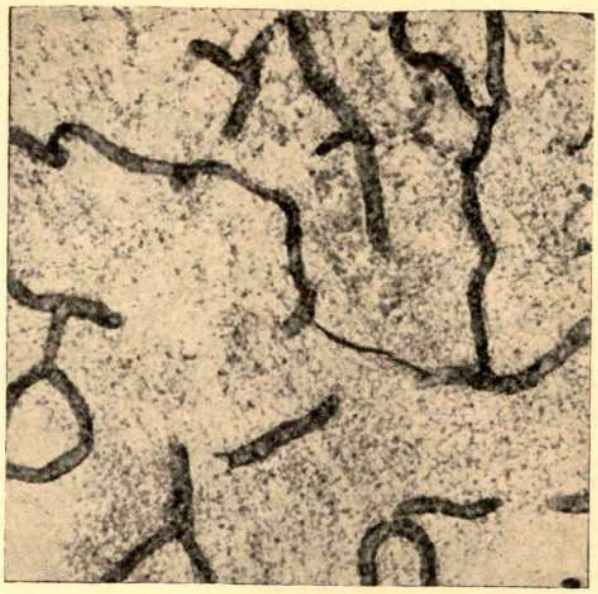

Fig. 7. Thalamus. Acetylcholinesterase-positive capillaries and threads (× *c.* 200)

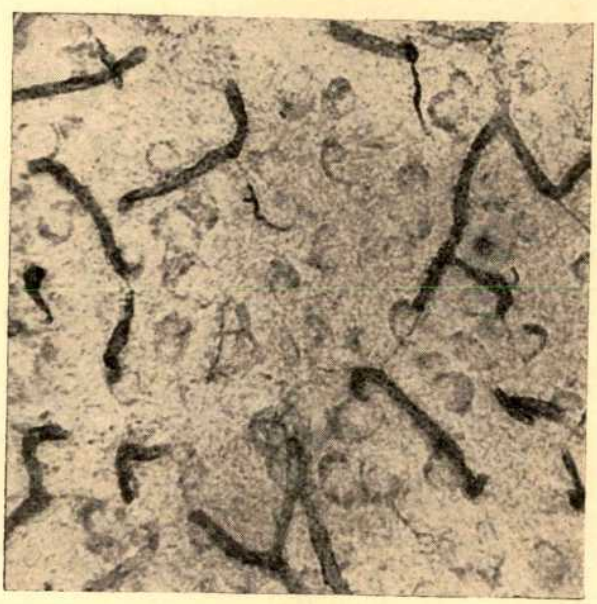

Fig. 8. Thalamus. Acetylcholinesterase-positive capillaries and threads (× 200)

(*C*) *Forebrain.* (Figs. 5, 6, 7 and 8.) Acetylcholinesterase-positive capillaries were more abundant in the region of the thalamus than in any other area of the brain investigated while none was present in the region of the hypothalamus. Indian ink preparations showed that capillaries in the thalamus were denser than those in the region of the hypothalamus bordering the third ventricle. No acetylcholinesterase-positive capillaries were observed in the cerebral cortex or corpus striatum although indian ink-filled capillaries were abundant.

Figs. 7 and 8 are high-power views of acetylcholinesterase-positive capillaries in the thalamus. They have a cylindrical appearance and are hollow on cross-section, indicating that the enzyme activity resides in the wall of the vessel and not within the lumen: although apparently endothelial, the exact site of activity has not been determined. Close inspection shows the presence

of isolated acetylcholinesterase-positive strands which link two or three capillaries together and terminate in their walls. The nature of these strands has not been investigated.

Discussion. Capillaries in most parts of the body do not give a histochemical reaction for cholinesterase but D'agostino and Rossatti[3] have shown acetylcholinesterase to be present in the walls of blood capillaries supplying the germinal centres of lymphatic follicles in mammals and man, and Cavanagh and Holland[4] describe acetylcholinesterase-positive capillaries in the spinal cord and brain stem of chicken. In addition, Koelle[2], Palmer and Ellerker[5] have described cholinesterase in the capillary walls of rats and sheep brains.

Gerebtzoff[6] believes that where cholinesterase localization in capillary walls occurs it is due to a common diffusion artefact. This is difficult to understand in the case of the present investigation because the acetylcholinesterase-positive capillaries are always present only in localized areas and by no means to those areas showing histochemically most tissue acetylcholinesterase, for example, corpus striatum.

Wolff[7] pointed out that the grey matter of the central nervous system is much more richly supplied with capillaries than is the white matter: this investigation has shown that acetylcholinesterase-positive capillaries are confined to parts of the grey matter and particularly to those parts where the capillary pattern is densest although the converse is not true—the cerebral cortex being devoid of acetylcholinesterase-positive capillaries.

The blood supply to the brain, despite the large number of publications, is still imperfectly understood. The pial vessels are known to be supplied with nerves and to react to adrenaline and acetylcholine, but little has been reported on the intrinsic capillaries. The findings of this investigation may perhaps be relevant to the innervation of these capillaries but no final conclusion can be drawn.

I thank H. F. Colgrave for the preparation of the specimens.

IMMUNOLOGICAL REACTIVITY OF BURSALESS CHICKENS IN GRAFT VERSUS HOST REACTIONS

By NOEL L. WARNER and A. SZENBERG
Walter and Eliza Hall Institute of Medical Research, Melbourne

THE bursa of Fabricius has recently been shown to play a fundamental part in the development of immunological competence in the chicken[1–3]. The original reports[1,2] showed that surgical removal of the bursa at one day of age or up to 2 weeks of age greatly impaired the subsequent capacity of chickens to produce circulating antibodies to protein and bacterial antigens. This suppressive effect of bursectomy was found to be even more marked if the development of the bursa was prevented in embryonic life by the injection of testosterone or some of its derivatives[2–4]. In investigations on the immunological competence of chicks reared from hormone-treated eggs, it was found that if the thymus in the bursaless birds were intact, then the capacity to reject foreign skin grafts was unaltered[3,5]. It was concluded from this work and from other investigations[6] that, in the chicken, the bursa of Fabricius is concerned with the development of antibody-forming capacity, and the thymus with the development of cells potentially capable of homograft immunity, that is, that there are at least two distinct populations of immunologically competent cells in the chicken.

Several reports by Papermaster *et al.*[7–9] have inferred, however, that chicks reared from embryos treated with 19-nortestosterone showed a deficient homograft response, as assessed by their ability to overcome immunological attack by adult homologous spleen cells, the tentative conclusion being that the lymphoid development and functions of the avian thymus and bursa are similar and are both suppressed by hormone. This is difficult to reconcile with our previous findings which show that the development of cellular homograft immunity is thymus-dependent and unrelated to the bursa of Fabricius. The aim of this present work was therefore to determine the basis of the impaired capacity of young bursaless chicks to reject homologous spleen cells.

All birds used in these experiments were outbred White Leghorn–Australorp hybrids. Bursaless chickens were obtained from eggs injected on the twelfth day of incubation with 4 mg of a corn-oil solution of testosterone proprionate (B.D.H.). Polyvalent tolerance was induced in 15-day-old embryos by the method of Hilgard *et al.*[10]. The recipient birds of one or both of these groups together with untreated controls were injected intraperitoneally with a washed spleen cell suspension prepared from adult birds. Two ages of recipients were used, those between 6–18 h post hatch were given 100 m spleen cells, and those 12-day-old post hatch were given 400 m spleen cells.

All birds were killed 6 days later and spleen and body-weights recorded. The graft versus host (*GVH*) index is the ratio of the mean spleen weight to mean body-weight, and the chimeric index[7] the ratio of the *GVH* index of the cell injected group to control group.

The results obtained with one-day recipients given spleen cells from normal birds are shown in Table 1. There is no statistically significant difference between the chimeric indices of any group. The presence of macroscopically visible lesions was observed equally in all groups. This type of assay does not seem to detect any homograft immunity in normal one-day recipients, as the chimeric index of the normals is not lower than that of the polyvalent tolerant chickens, and there is certainly no evidence that the bursaless chickens were more susceptible to immunological attack by the homologous spleen cells as was suggested by Papermaster *et al.*[7].

These results (Table 1) thus fail to confirm those of the American workers and we can only suppose that there is some difference in the birds used or in the way they were handled. With the 12-day recipients, however, this was not the case. Table 2 shows the results obtained, in which

Table 1. GRAFT VERSUS HOST REACTION IN 1-DAY CHICKENS

Group	Mean body-weight (g)	Mean spleen-weight (mg)	*GVH* index	Control *GVH* index	Chimeric index
Normal	43·4	63·3	1·53(33)	0·86(22)	1·78
Bursaless	40·7	28·6	0·70(31)	0·46(20)	1·55
Polyvalent tolerant	35·5	46·6	1·31(15)	0·90(14)	1·46

GVH index is the ratio of spleen-weight to body-weight, control *GVH* index being the value for an uninjected similar group of chickens. Values in brackets in fourth and fifth column show the respective numbers of chickens per group. Homologous spleen cells were from normal adult donor fowls.

it is evident that there is an impairment of the ability of these bursaless chickens to counteract the attack of the homologous spleen cells. Thymic sections from these birds showed them to be completely normal in this regard, so impairment of homograft immunity due to failure of thymic development is apparently not involved.

Table 3 demonstrates that spleen cells from two four-month-old bursaless birds were fully competent in initiating a graft versus host reaction in 1-day normal recipients.

As both the rejection of homologous spleen cells and the initiation of a graft versus host reaction by spleen cells are in all probability directed towards the same antigens, we must attempt to reconcile the results of Tables 2 and 3. In view of the latter results (Table 3) and our previous observations[5] showing that bursaless fowls have full competence to reject skin grafts, it is felt that the heightened chimeric index of the 12-day bursaless recipients cannot be ascribed to a failure of the population of cells associated with the cellular response to transplantation antigens.

Table 2. Graft versus Host Reaction in 12-day Chickens

Group	Mean body-weight (g)	Mean spleen-weight (mg)	*GVH* index	Control *GVH* index	Chimeric index
Normal	104·0	225	2·13(12)	1·45(15)	1·48
Bursaless	86·7	102·3	1·20(13)	0·52(12)	2·31

See legend to Table 1.

Table 3. Graft versus Host Reaction in 1-day Normal Recipients induced by Spleen Cells from Bursaless Birds

Mean body-weight (g)	Mean spleen-weight (mg)	*GVH* index	Control *GVH* index	Chimeric index
43·0	63·0	1·41	0·82	1·72

cf. with Table 1, in which chimeric index for normal recipients given normal adult homologous spleen cells was 1·78.

There are at least two other alternative explanations. (1) The spleen of bursaless chickens is relatively poor in lymphoid elements and there may simply be more potential space available for the proliferation of reacting host and donor elements. (2) If the difference is more directly immunological in nature it is likely that the failure to suppress the immunological attack is associated with the failure of antibody production. There are growing indications from mammalian systems that circulating antibody may play a part in the complex process of homograft rejection. We are specially interested in the possible significance of the *B* group hæmagglutinins in the chicken since their relation to histocompatibility reactions was shown by Schierman[11]. Search for the relevant cytotoxic antibodies is being undertaken in this laboratory and in due course we hope to be in a position to determine experimentally whether these known or possible antibodies related to histocompatibility antigens are under the control of thymus, bursa, or both organs.

Whatever the eventual decision, we see no reason to modify our opinion that the thymus and not the bursa is concerned with cellular histocompatibility reactions. Papermaster and Good have confirmed our earlier finding that lymphoid cells of bursaless chickens are fully capable of provoking graft versus host reactions[9], so that it is difficult to understand their contention that the functions of bursa and thymus in the chicken are similar. All the available evidence is consistent with the view that the thymus and bursa are concerned with the development of two basically different populations of immunologically competent cells, the precise nature of which is yet to be completely determined. This work was supported by a research grant from the N.H.M.R.C., Canberra, which is gratefully acknowledged.

INHIBITION OF RIBONUCLEIC ACID-POLYMERASE REACTIONS BY ACTINOMYCIN AND PROFLAVINE

By Dr. I. H. GOLDBERG, Dr. E. REICH and Dr. M. RABINOWITZ

Departments of Medicine and Biochemistry, University of Chicago; Laboratory of Biochemical Genetics, Rockefeller Institute, New York; Argonne Cancer Research Hospital, Chicago

ACTINOMYCIN inhibits DNA-directed RNA* synthesis of intact cells[1] and enzyme preparations[2–4], and this inhibition is dependent on the ability of the antibiotic to bind to the DNA primer[3–6]. Several effects of actinomycin on RNA-polymerase activity appeared inconsistent with the view that the antibiotic acted simply by obstructing polynucleotide chain growth. One unexplained phenomenon concerns the different susceptibility to actinomycin of DNA and RNA synthesis[4]. The most puzzling observation relates to homopolymer formation which, in the case of DNA-directed poly A and poly U formation, is very resistant to actinomycin[4,6]. Since heteropolymer synthesis is very sensitive to the antibiotic, it might be expected that the presence of actinomycin would shift the enzymatic reaction toward the formation of homopolymers. However, this does not occur, suggesting that in the presence of actinomycin the enzyme might be fixed on portions of the DNA incapable of priming homopolymer formation. We have, therefore, investigated the possibility that actinomycin may be involved in a reaction which binds RNA-polymerase to DNA. The results reported here demonstrate that this is not the case. In addition, we have attempted to establish whether biologically inactive actinomycin derivatives might compete with the parent compound and prevent the inhibition by the latter of RNA-polymerase; this possibility has also been ruled out. Finally, we have investigated the action of proflavine on RNA synthesis primed by synthetic DNA's in order to differentiate the effect of this compound from that of actinomycin.

The details of enzyme isolation, and assay, and the preparation of radioactive nucleoside triphosphates have been described previously[6]. All experiments were performed at an enzyme concentration corresponding to the linear portion of the velocity/enzyme concentration curve.

The possibility that enzyme binding to DNA might be a factor in the action of actinomycin was tested in the following manner: The synthesis of polynucleotides by RNA-polymerase is known to be insensitive to actinomycin when the primers do not bind the antibiotic, for example, when dAT or polyribonucleotides are used as primers[6–8]. If inhibition of RNA polymerase by actinomycin were related to binding of enzyme to DNA, the presence in a reaction mixture of a DNA species (for

RNA synthesis was measured according to Chamberlin and Berg (ref. 10) for 30 min at 37°. In Exps. 1 and 2, calf thymus DNA (highly polymerized, obtained from Sigma Chemical Co., St. Louis, Missouri) was present at 48 mμmoles, and in Exp. 3 at 6 mμmoles per 0·25 ml. reaction volume. Synthetic and crab dAT were added, where indicated, at 0·01 O.D. units (260 mμ) per 0·25 ml. Enzyme preparation equivalent to 2 μg protein was used in Exps. 1 and 2, and 3 μg protein/0·25 ml. in Exp. 3. The specific activity of UT^{32}P was 4×10^6 c.p.m./μmole. In an experiment conducted in parallel with Exp. 3, the RNA product was subjected to alkaline hydrolysis (0·3 N potassium hydroxide, 18 h, 37°) and the radioactivity of the resulting 2′ (3′) nucleoside monophosphates analysed following paper electrophoresis (0·05 M citrate buffer, *p*H 3·5); the results showed that when both calf thymus DNA and crab dAT were present as indicated, the priming due to calf thymus DNA accounted for 18 per cent of the total RNA produced in the absence of actinomycin; in the presence of actinomycin the product resulted entirely from priming due to crab dAT.

example, calf thymus DNA) known to complex the antibiotic should result in the immobilization of at least some of the available enzyme. Under conditions in which enzyme concentration is rate limiting the addition of calf thymus DNA to dAT or poly A-primed reactions should render the latter partially susceptible to actinomycin. The results in Table 1 demonstrate that this is not the case. The presence of a large excess of calf thymus DNA in the dAT-primed reaction mixtures markedly lowers the overall reaction rate; dAT is the most efficient DNA primer for RNA synthesis (a reflexion of its high AT content) and calf thymus DNA presumably competes with the dAT for the enzyme. The addition of actinomycin does not further lower the reaction rate, as would be expected if the antibiotic facilitated enzyme binding to and consequent immobilization on the calf thymus DNA. On the contrary, the antibiotic reproducibly stimulates the reaction conducted with UT^{32}P and ATP alone, and does not significantly affect the synthesis in the presence of four NTP. These results are compatible with the displacement, by actinomycin, of a fraction of the enzyme bound to calf thymus DNA, and appear to rule out antibiotic-dependent enzyme binding to DNA. Corroborative evidence is presented in Table 2. In this experiment the actinomycin-sensitive primer was *Micrococcus lysodeikticus* DNA, and poly A was the actinomycin-resistant primer. Alkaline hydrolysis of the product of the mixed reaction (tube 3), followed by analysis of the radioactivity of the resulting 2′ (3′) nucleoside monophosphates, revealed that 26 per cent (0·20 mμmoles) of the incorporation of UM^{32}P was due to *M. lysodeikticus* DNA priming, the remainder (0·57 mμmoles) being due to poly-A. As

Table 2

μg/0·25 ml. Poly A	DNA mμmoles/0·25 ml. *M. lysodeikticus*	Nucleotide	Actinomycin (μg/ml.)	UM^{32}P incorporated (mμmoles)
5	—	UT^{32}P, ATP, CTP, GTP	—	0·83
5	—	UT^{32}P, ATP, CTP, GTP	40	0·80
5	48	UT^{32}P, ATP, CTP, GTP	—	0·77
5	48	UT^{32}P, ATP, CTP, GTP	40	0·66
—	48	UT^{32}P, ATP, CTP, GTP	—	0·37
—	48	UT^{32}P, ATP, CTP, GTP	40	0·01

Assay conditions as in Table 1, but performed at 25°, 30 min, in final volume of 0·25 ml. containing 4 μg enzyme protein. Analysis of the nature of the radioactive product revealed that with both poly A and *Micrococcus lysodeikticus* DNA present, the priming due to poly A accounted for 74 per cent of the RNA synthesized in the absence of actinomycin.

Table 3

	AMP-^{14}C incorporated (mμmoles)
Control	1·32

+ Actinomycin C_1, 0·5 μg/ml.	0·54
+ Actinomycin C_1 (0·5 μg/ml.) + *N*-β-aminoethylactinomycin C_2-25 μg/ml.	0·47
+ Actinomycin C_1 (0·5 μg/ml.) + *N*-*p*-aminophenylactinomycin C_2-25 μg/ml.	0·52

Assay conducted as in Table 1, 30 min, 37°, in 0·25 ml. containing 6 μg enzyme protein ATP-8-^{14}C (sp. act. 6·8 μc./μmole, obtained from Schwarz Bioresearch, Mt. Vernon, New York), was the radioactive precursor. Calf thymus DNA was present at 30 mμmoles deoxynucleotide/0·25 ml.

Table 4

		GMP incorporated (mμmoles)	Inhibition (per cent)
Control		0·704	
+ Proflavine	30 mμmoles/ml.	0·362	49

Experiment performed as in Table 1, 30 min, 37°, in final volume of 0·25 ml. containing 1·5 μg enzyme protein. The radioactive precursor was GTP-8-^{14}C (spec. act. 8·28 μc./μmole), obtained from Schwarz Bioresearch, Mt. Vernon, New York. dGC was present at 7·4 mμmoles/0·25 ml.

already seen with calf thymus DNA and dAT, the addition of actinomycin to the mixture stimulates modestly the poly-A primed reaction. This finding would be expected if actinomycin prevented the attachment of some enzyme molecules to *M. lysodeikticus* DNA, thereby making them available for poly A-primed RNA formation. A similar observation has been recorded by Weiss[8] using a system of mixed primers in which calf thymus DNA was the actinomycin-sensitive and polycytidylic acid the actinomycin-insensitive primer for RNA synthesis.

Lack of competitive relationship between actinomycin and inactive derivatives. The results in Table 3 show that two biologically inactive derivatives[5] of actinomycin were incapable of relieving the inhibition of RNA polymerase caused by a much smaller concentration of an active compound. It is noteworthy that one of the inactive compounds, *N*-β-aminoethyl actinomycin, interacts with DNA, but in a manner which does not affect the functional activity of DNA *in vivo* or *in vitro*[5].

Effect of proflavine on RNA synthesis primed by dAT and dGC. Previous work has shown that proflavine inhibits DNA-directed RNA synthesis of enzyme prepara-

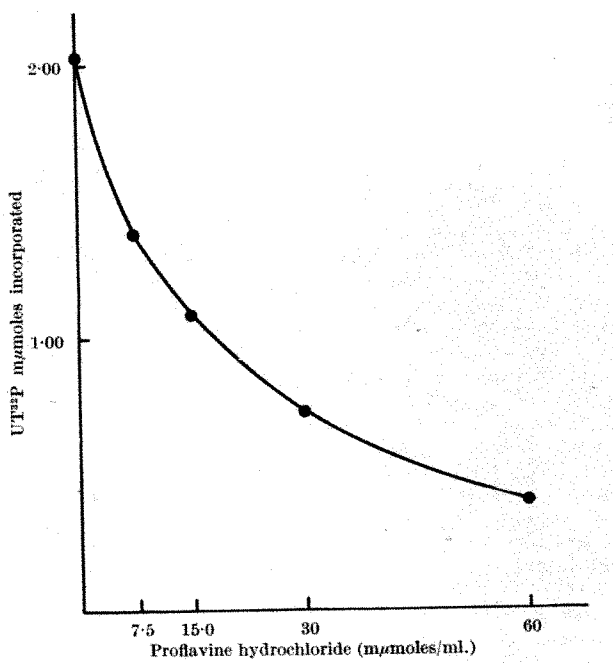

Fig. 1. Effect of proflavine on RNA synthesis primed by dAT. The reaction mixture contained 0·005 O.D. units (260 mμ) synthetic dAT and 4·1 μg enzyme protein in a final volume of 0·25 ml. UT^{32}P ($1·1 \times 10^6$ c.p.m./μmole) was the radioactive precursor. Incubation was for 15 min, 37°

tions from animal[2] and bacterial[4] sources. In view of the specificity of actinomycin action, which depends on the presence of guanine in DNA primers[6], it was of interest to establish whether proflavine effects demonstrated similar, if any, specificity for inhibition of RNA synthesis. The results in Fig. 1 and Table 4 show that this is not the case; proflavine inhibits both dAT- and- dGC-primed syntheses, whereas actinomycin affects only the latter. It is known that actinomycin which is bound to one strand of the dGC inhibits RNA synthesis from both. The results presented here do not establish whether this is the case for proflavine since the priming action of only one strand—the polydeoxycytidylic—has been assayed in this experiment. In view of the suggestion[9] that proflavine molecules are intercalated between the base pairs of DNA, it might be expected that all enzymatic reactions involving either strand of DNA would be inhibited by this dye.

From previous work it has been concluded that the inhibition of RNA synthesis by actinomycin is based exclusively on the binding of the antibiotic to priming DNA in some manner involving the guanine residues[6]. The experiments reported in this article support these conclusions. The tight binding to DNA may be visualized as obstructing polyribonucleotide chain growth, without affecting the ability of the enzyme, RNA-polymerase, to catalyse the synthesis of RNA from primers (such as dAT or poly-A) which do not bind the antibiotic. The inactive derivatives tested are not bound to DNA in the manner of the parent compounds and, consequently, do not compete with the latter. The effect of actinomycin, its specificity, and, therefore, the principles of its binding to DNA, are thus differentiated from those of proflavine. The failure of actinomycin-inhibited RNA synthetic reactions to switch to resistant homopolymer formation remains unexplained. It has been shown[10] that the presence of other nucleoside triphosphates reduces DNA-directed poly A synthesis in the absence of actinomycin. As anticipated, poly A synthesis is intrinsically very actinomycin-resistant since the supposed priming sequences in DNA would not bind the antibiotic[6]. Therefore, it is of interest that the presence of all four NTP is incompatible with homopolymer synthesis even in the presence of high concentrations of actinomycin[6]—a condition in which RNA synthesis is virtually undetectable. The results presented here exclude the possibility that an actinomycin-mediated immobilization of enzyme might be responsible for this finding, and suggest that the presence of all NTP is itself incompatible with homopolymer growth independently of concurrent RNA synthesis. This effect of NTP may be due to interference with a 'slippage' mechanism as previously proposed[10].

We thank Dr. E. L. Tatum for encouragement; Dr. A. Kornberg, Stanford University, for gifts of dAT and dGC; Dr. N. Sueoka, Princeton University, for a gift of a crab dAT; and Dr. W. Müller, University of Göttingen, for gifts of the actinomycin derivatives. This work was supported by the American Cancer Society (I. H. G.), the Helen Hay Whitney Foundation (E. R.), and the U.S. National Institutes of Health.

ASPIDIN : THE PRECURSOR OF BONE

By Dr L. B. HALSTEAD TARLO*
Department of Geology and Mineralogy, University of Oxford, and Royal Dental Hospital of London

It has previously been believed that aspidin[1], the calcified tissue forming the bulk of the plates of the carapace of the heterostracan ostracoderms—the earliest known vertebrates—was acellular[2]. In consequence, it was thought by Stensiö and Ørvig[3] that like the bone of modern teleosts it had been derived secondarily from normal bone. Since, however, aspidin precedes the first incontrovertible evidence of bone in the fossil record by about 100 million years, and since bone is just as easily preserved as aspidin, until definite evidence to the contrary is produced, it seems reasonable to take aspidin as the most primitive calcified tissue, rather than bone. Aspidin of successive geological ages has therefore been examined, and its development has been traced in time through the various heterostracan groups.

In forms from the Ordovician Period (about 500 million years ago) such as *Astraspis* and *Eriptychius*, this tissue was deposited as successive lamellæ in concentric rings or aspidones[4] around vascular spaces, by cells named aspidinoblasts by Bystrow[5]. These must have originated in the vascular tissue and retreated as calcification occurred, since no cells seem to have become trapped in the hard tissue. Occasionally, however, very fine tubules are visible normal to the lamellæ, which can best be explained as canaliculi formed around the processes of the aspidinoblasts[6]. Tubules of this type are more numerous in the superficial tubercules of the carapace of *Astraspis*, and it may well be that it was at this stage that the tissue dentine became differentiated from aspidin. In later forms such as the early Devonian genera *Kallostrakon*, *Tesseraspis* and *Weigeltaspis*, the aspidin is permeated by randomly arranged spindle-shaped structures, although at the growing edges of the plates these are seen to be aligned parallel to the direction of growth, and are greatly elongated. Such structures have long been observed[2]; but they have been identified as representing the former position of bundles of collagen, and in fact the general practice has been to name them fibres of Sharpey[5,7], regardless of their position or alignment. However, fibres of Sharpey are not a component of internal systems, but are usually found anchoring one tissue to another, and this is not the case with the spindle-shaped structures in aspidin.

In more advanced heterostracans such as *Tartuosteus*, *Psammolepis*, and *Psammosteus*, these structures are no longer scattered throughout the tissue, but are now organized in a well-defined pattern. They are very abundant in trabeculæ which seem to have been laid down before the concentric lamellæ of the aspidones were apposited (Fig. 1), and can now be seen to be spindle-shaped cell spaces crossing each other in all directions. But it should be noted that they are not in direct contact with one another (Fig. 2). The spaces can thus be best understood

* Nuffield Research Fellow.

Fig. 1. *Psammosteus*. Vertical section of advanced aspidin showing aspidinocytes with random arrangement in trabeculæ, and with orientation parallel to lamellæ of aspidones. (× 120)

Fig. 2. *Psammosteus*. Enlargement of single aspidinocyte. (× 400)

as marking the former position of aspidinocytes which became trapped in hard tissue, after being responsible during their role as aspidinoblasts for the production of the organic matrix on which calcification took place. The cells can thus be compared directly with osteoblasts which can also be spindle-shaped, and it may well be that in aspidin, which appears to represent a primitive stage in the development of hard tissues, both aspidinoblasts and aspidinocytes were normally spindle-shaped.

The cells in the trabeculæ do not appear to have moved, but instead, as the lamellæ of the aspidones were laid down, some of the aspidinocytes seem to have developed cytoplasmic extensions at one end, which became further and further drawn out in an attempt to maintain contact with the source of nutriment. This seems to parallel closely the situation in cementum, where cementocytes frequently behave in much the same way. Although in general the aspidinoblasts responsible for the production of the lamellæ in advanced aspidin do not seem to have become enclosed, nevertheless spindle-shaped spaces can also be seen occasionally between successive layers of the aspidones, orientated parallel to them (Fig. 1). These presumably mark the position of the few cells which did become trapped during calcification, and which thus resemble the osteocytes of primary osteones in bone.

When aspidin of successive geological ages is studied under polarized light, it is evident that there is also a gradual change in the organization of the organic matrix towards the condition found in modern bone. In the Ordovician genera the tissue consists of simple lamellæ in which the apatite crystallites appear to have been aligned parallel to the surface of apposition, and it seems reasonable, therefore, to infer that the original collagen fibrils were also so aligned. This same basic arrangement occurs in modern dentine, and supports the idea that dentine could have been derived from an aspidin-like tissue at an early stage of evolution. In forms from the Lower Devonian such as *Kallostrakon* and *Tesseraspis*, a very broad black-and-white banding is visible, suggesting that the collagen fibrils had become aligned alternately in broad zones, while in the Upper Devonian *Psammosteus*[1] and *Obruchevia* (*Aspidosteus*), a much finer black-and-white banding can be seen which is virtually indistinguishable from that well known in mammalian bone (Fig. 3). Thus, the most advanced heterostracans demonstrate that, in the organization of its organic matrix, aspidin reached the same condition as is known in true bone.

Furthermore, it was believed in the past that, since remodelling did not occur in aspidin, there was a fundamental difference between this tissue and bone. Nevertheless, Gross[4] was convinced that resorption must have taken place in the Heterostraci, and suggested the base of the middle layer of the plates as a likely site, although he was unable to produce any concrete evidence for his theory. Now, however, it is possible to demonstrate resorption in aspidin, but it is seen to occur in the more superficial part of the plates beneath the tubercles, and not where suggested by Gross. Initially, dense aspidin seems to have been laid down which was then opened out to form larger vascular spaces, indicating the presence of cells which can be called aspidinoclasts. Areas of resorption can be seen clearly where the concentric lamellæ of the aspidones have been either partially eroded or completely breached (Fig. 4). Occasionally, also, very simple secondary aspidones clearly delineated by a marked cement line are found filling in formerly resorbed areas

Fig. 3. *Obruchevia* (*Aspidosteus*). Advanced aspidin under polarized light (crossed nicols), showing alternate light and dark banding. (× 75)

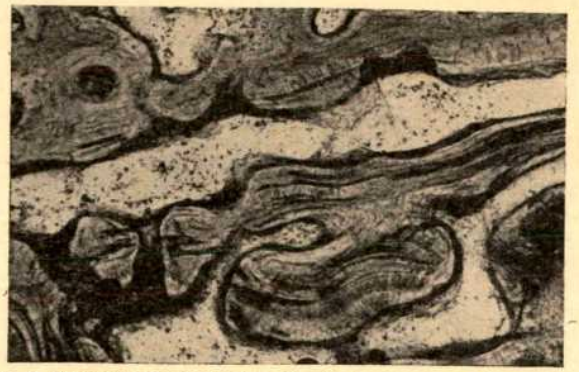

Fig. 4. *Ganosteus*. Vertical section showing irregular areas of resorption cutting into and through lamellæ of aspidones. (× 75)

(Fig. 5). These are obviously directly comparable with secondary osteones in the higher vertebrates.

Aspidin, therefore, seems to have had the essential attributes of bone even though it was not as highly organized in some respects. With its similar basic composition[8], its almost certain possession of cells with the same role as osteoblasts, osteocytes and osteoclasts, with the gradual organization of its collagen fibrils into alternate layers, and with its ability to remodel, aspidin must surely be considered as a primitive type of bone, or as the precursor of true bone. This seems much more reasonable than that it was a highly specialized and unusual tissue derived from bone, particularly in view of the fact that, in time, the gradual evolution of aspidin can be followed towards true bone, and not in the opposite direction.

SUCCESSFUL RE-INTRODUCTION OF THE MURPHY–STURM LYMPHOSARCOMA AFTER METHYLCELLULOSE-INDUCED REGRESSION OF THIS TUMOUR IN RATS

By Dr. ALLAN W. LAZAR and DIANE E. CHILDRESS LAZAR
Department of Pathology, University of Chicago Hospitals and Clinics

IN our laboratory, and in others[1], complete, spontaneous regression of the Murphy–Sturm lymphosarcoma[2] in rats results in life-long resistance, on the part of such an animal, to the successful re-introduction of this tumour. If re-introduced, the tumour will not grow.

Over a period of three years we have maintained this tumour, by serial passage, in a total of more than 350 adult, Sprague–Dawley rats. Growth of the tumour, after its subcutaneous inoculation, occurred in 99 per cent of the rats and, after attaining a moderate size in 10–13 days, spontaneous regression of the tumour occurred in 20 per cent of the rats. The rest of the rats died, with progressively growing tumours, in 21–35 days. We have observed no association of symptoms in these animals, such as might be due to an infectious agent[3], in any significant degree to lead us to suspect a causal relationship between such an agent and regression of the tumour.

We define regression as the absence of tumour by palpation during life and followed by absence of tumour in a complete gross and histopathological post-mortem examination which includes careful dissection and multiple histological sections from the site of injection of the tumour.

Methylcellulose, which has been found to induce regression of some transplantable tumours in rats[4–6], is a long-chained polymer; a methyl ether of cellulose which forms a colloidal suspension in water. It is not absorbed in appreciable amounts from the alimentary tract[7,8]. Anatomical and physiological changes, after parenteral administration of amounts of methylcellulose comparable with those used in our investigations, include: hypersplenism and hæmolytic anæmia[9,10]; quantitative and qualitative changes in circulating γ-globulins[6,9]; changes in serum lipoproteins[11]; decrease in the formation of hæmolysin[9,12]; decreased coagulability of the blood[13]; storage of methylcellulose in the glomeruli and a nephrosis-like syndrome[14]; and storage of large amounts of methylcellulose in macrophages, especially in the liver and spleen[5].

We have no evidence for a direct cytotoxic effect by methylcellulose. Its action in the regression of tumours requires the presence of the spleen[5]; the mode of this action is probably an enhancement of the homograft reaction by some mechanism, as yet, not clear.

In the work recorded here we transplanted the Murphy–Sturm lymphosarcoma subcutaneously into rats which had had a methylcellulose-induced regression of a similar tumour a few weeks before. The injections of methylcellulose were continued but the animals were not 'conditioned' by any of the usual means of abrogating immunological resistance (total-body X-irradiation, adrenal cortical steroids, etc.). After the usual latent period, the second tumour grew and, again, regressed. Subsequent attempts to transplant the tumour into these rats resulted in no growth. Adequate controls demonstrated the potency of all the tumours used for transplantation.

Non-litter-mate, male, adult Sprague–Dawley rats, 300–360 g, were divided into 4 groups averaging 340–350 g. All the animals were fed Purina laboratory rat chow and water, *ad lib.*, throughout the study.

The methylcellulose ('Methocel 400 CPS', U.S.P., Dow Chemical Co.) was prepared as a clean, but not sterile, 2·5 per cent aqueous suspension and kept under refrigeration; aliquots were removed from this stock solution as needed.

Each Murphy–Sturm tumour used for transplantation had been given to its respective host (donor) rat 14 days previously. These donors were killed, while under ether anæsthesia, by cutting the aorta. The tumour was quickly removed and homogenized in cold saline using a clean but not sterile technique. A cell-count was done and the volume of homogenate containing 2×10^7 tumorous cells was inoculated subcutaneously with as little delay in the procedure as possible. The site of injection was different for the first, second and third transplantations; the control animals were always inoculated in the same site as the experimental group inoculated at the same time. The first transplantation was in the area of the right scapula; second in the area of the left scapula; third in the lumbar area.

Measurement of each tumour was carried out daily with a caliper and the volume of the tumour was calculated[6].

The treated group (*A*) of 40 rats received 2 c.c. of 2·5 per cent aqueous suspension of methylcellulose intraperitoneally 3 times per week (Monday, Wednesday, Friday) starting 10 days before transplantation of the tumour. Once started, the injections were continued, on this same dosage schedule, as long as the animal remained alive.

The control group (*B*) of 26 rats received the same tumour at the same time as group *A*, but were otherwise untreated.

Control groups *C* and *D* of 20 rats each were from the same shipment as the foregoing groups and comparable in sex and size. They were untreated and used for testing the potency of the tumours utilized for the second and third transplantations.

The tumour was transplanted into all the animals in groups *A* and *B*, became established in all these animals, and grew to approximately the same average size for both groups in the first 11 days. Thereafter, regressions began in 38 (95 per cent) of the rats in the treated group (*A*), and 6 (23 per cent) of the rats in the control group (*B*).

Considering as sub-group *A′* only those 38 rats in group *A*, and as sub-group *B′* only those 6 rats in group *B*, in which there was subsequent regression of the first tumour, the following differences were noted between these two sub-groups: (1) although the maximum average size of the tumour in both these sub-groups was reached 11 days after transplantation, the average size of the tumours was 100 per cent larger in the 6 untreated control rats (*B′*); (2) the regressions were completed by the twenty-first day after transplantation of the tumour in the 38 treated rats (*A′*), but not until the twenty-eighth day in the 6 control rats (*B′*).

Forty days after the first transplantation, 12 of the 38 rats in sub-group *A′* which had methylcellulose-induced regression of the first tumour, and all 6 of the rats in sub-group *B′* which had spontaneous regression of the first tumour, were re-inoculated with Murphy–Sturm tumour, in the same manner as here, but in the second site. In addition, control group *C* was inoculated with this second tumour.

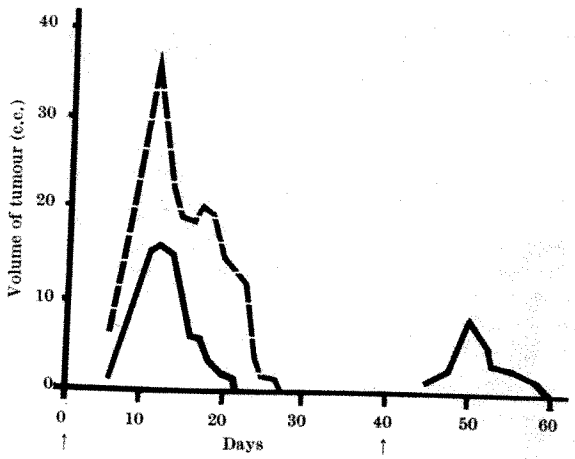

Fig. 1. Arrows indicate transplantation of tumour. Comparison of average size of tumours which regressed after first transplantation (spontaneously and induced by methylcellulose) and after second transplantation (methylcellulose-induced)
——, Treated sub-group *A′*; – – –, control sub-group *B′*

The tumour used for the second transplantation was of usual potency; it established in all 20 of the rats in control group *C* and caused the death of 17 of them by the thirtieth day after transplantation; 3 had spontaneous regression.

As expected, there was no growth of the second tumour in the 6 rats in sub-group *B′*.

In 9 of the 12 rats from sub-group *A′* the tumour established, grew to its maximum average size in 10 days, and then completely regressed in all 9 of the rats by the twentieth day after transplantation. Fig. 1 shows the average size of the tumours in all 38 rats in sub-group *A′* during the first methylcellulose-induced regression as compared with the 9 rats from sub-group *A′* in which there was methylcellulose-induced regression of the second tumour. The larger size of the tumours which regressed spontaneously in the 6 rats in sub-group *B′* is shown for comparison.

All the rats which had regression of the tumour, either spontaneously or induced by methylcellulose, maintained a generally healthy appearance and gained weight.

A third subcutaneous inoculation of the tumour was performed, 40 days after the second transplantation, in: the 9 rats in sub-group *A′* which had had methylcellulose-induced regression of both previous tumours; the 3 rats in sub-group *A′* which had methylcellulose-induced regression of the first tumour, but no growth of the second tumour; the 6 rats in sub-group *B′* which had spontaneous regression of the first tumour and no growth of the second tumour; and the 20 previously unused rats in control group *D*.

The tumour established and grew in all the rats in control group *D*, killing 16 of them by the twenty-eighth day after transplantation; 4 had spontaneous regression. None of the other rats which were inoculated with this tumour had any detectable growth of the tumour 20 days after inoculation, at which time they were killed for internal examination.

All the animals in this investigation, which remained alive 20 days after the third inoculation of the tumour, were killed at that time and a complete post-mortem examination was made of each. Tissues were fixed in formalin, embedded in paraffin, cut at 6μ, and stained with hæmatoxylin and eosin. Multiple cut surfaces and at least one histological section were made from each of the following organs from each rat: heart, lung, liver,

spleen, abdominal lymph nodes, mesentery, pancreas, testis, small intestine, and femoral bone-marrow. The sites of inoculation of tumour were all examined grossly and multiple histological sections were made from each site. In addition, the peripheral lymph nodes draining the sites of inoculation of tumour were also examined histologically. None of the gross or histological sections of internal organs, sites of injection, or peripheral lymph nodes, contained tumour. The changes due to storage of methylcellulose were similar to those reported elsewhere[5].

This work was supported by grant *CF*–9810 (*C*1) of the National Cancer Institute and by the American Cancer Society.

TONIC STRETCH REFLEXES IN THE CALF MUSCLES OF NORMAL HUMAN SUBJECTS

By R. F. MARK*

Laboratoire de Psychophysiologie, Faculté des Sciences, Marseille, France

A REFLEX response to muscle stretch, the tendon jerk, can be demonstrated in most individuals by a tap on one of several suitably placed tendons. Should the responses be small or difficult to evoke it has long been known that they may be temporarily exaggerated by any prolonged voluntary muscle contraction occurring elsewhere in the body. The usual method when examining the leg reflexes is to ask the subject to perform Jendrassik's[1] manœuvre of sustained traction exerted between the linked right and left hands. The increase in amplitude of the reflex responses is brought about indirectly by a heightening of the sensitivity of the muscle stretch receptors which is thought to be caused by the activation of the γ-motoneurones supplying the intrafusal muscle fibres of the muscle spindles. Contraction of the intrafusal fibres leads to a tensing of the annulo-spiral ending and thus an increased response to stretch. The excitability of the large motoneurones supplying the leg muscles does not seem to be directly affected[2–4].

In a normal relaxed person the response to muscle stretch is dependent on the abruptness of the stimulus for if the same amount of stretch is applied slowly no active opposing contraction occurs. Continuously exaggerated responses to slow stretch are only seen in man in certain disorders of the nervous system, just as they may become obvious in experimental animals with certain brain lesions, notably intercollicular decerebration[5]. In both man and animals it has been shown that in some, though not all, of these cases the sensitization of the stretch reflex arc is due to increased activity of the γ-motoneurones acting on the intrafusal fibres supporting the annulospiral ending of the muscle spindles[6,7]. This is the same mechanism as is known to underlie the temporary augmentation of tendon jerks by the performance of the Jendrassik manœuvre in normal man. It was therefore thought of interest to determine whether the Jendrassik manœuvre had any effect on the response of human muscles to slow or maintained stretch.

The experiments were performed on six apparently normal young adults, men and women. They lay face downward on a couch with their right foot fixed to a flat plate mounted on a pivot allowing full flexion and extension of the ankle joint. A system of springs kept the foot in mid-position from where it could be moved through a variable number of degrees of dorsiflexion by a chain attached to a heavy piston moving vertically in an oil-filled cylinder.

The standard passive stretch of the triceps suræ muscles resulted from a dorsiflexion of the ankle joint of 5° in 1·5 sec which was accomplished by the free descent of the piston. At the end of the passive movement the foot remained dorsiflexed until the piston was pumped back towards the starting point. The triceps suræ could also be stretched without simultaneous movement of the ankle joint by pressing slowly and steadily on the Achilles tendon while holding the foot still, although the rate and degree of muscle stretch could not then be controlled accurately from trial to trial as in the case of dorsiflexion of the foot. Surface electrodes were placed over the triceps suræ muscles and over the antagonistic tibialis anterior muscle on the anterior surface of the leg. Another pair of electrodes were fixed over the extensors of the right wrist to indicate the timing and the intensity of the Jendrassik manœuvre. Muscle action potentials were amplified and displayed on a pen-writing Offner dynograph. A potentiometric device for measuring the position of the foot was connected to one of the channels of the dynograph so that electromyographic activity could be observed in relation to the passive movement of the ankle joint.

In the normal relaxed subject a passive dorsiflexion of the ankle joint of 5° in 1·5 sec was not accompanied by any recordable electromyographic activity of the calf muscles or of their antagonists. Occasionally in the first few trials subjects would tend to follow the applied movement of the foot with a contraction of the dorsiflexors of the ankle joint, but when they became used to the conditions of the experiment and relaxed completely this was no longer seen. Subjects were then asked to perform a series of Jendrassik manœuvres of different intensities as judged by the electromyogram of the extensors of the wrist joint. It was found that a manœuvre performed with all the subject's strength would frequently be associated with contraction of the muscles of the legs including those monitored. With the expenditure of somewhat less effort there was no movement of the legs and no electromyographic activity of the triceps suræ or of the tibialis anterior.

Several seconds after the beginning of one of the Jendrassik manœuvres which did not evoke any overt activity of the leg muscles the descent of the piston was triggered and the passive dorsiflexion applied to the foot. As soon as the foot began to move from the neutral position an irregular shower of action potentials appeared in the

* Holder of a Wellcome Trust Research Travel Grant. British Medical Research Council Scholar to the Centre National de la Recherche Scientifique, France. Present address : Division of Biology, California Institute of Technology, Pasadena.

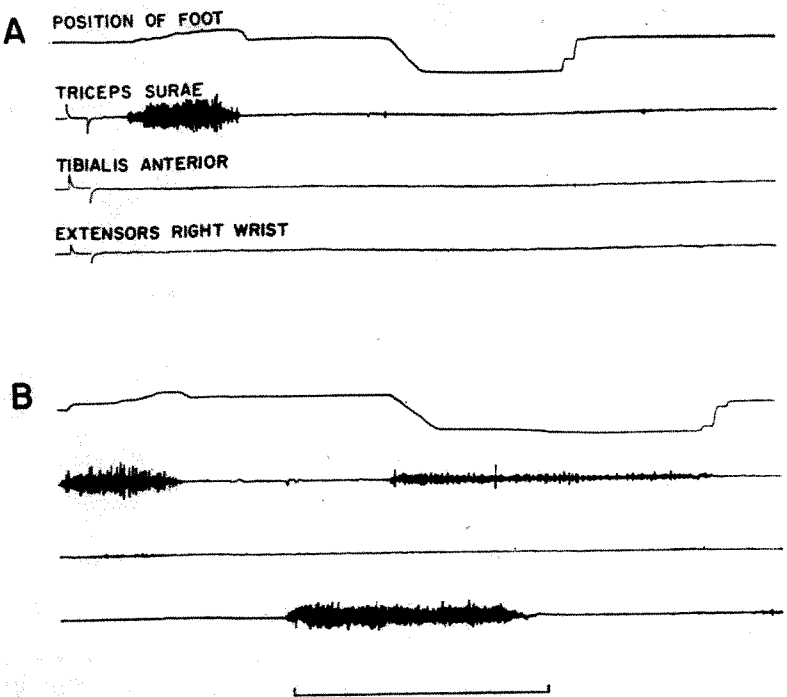

Fig. 1. Electromyographic responses of the triceps suræ to slow passive dorsiflexion of the foot

A, Top line indicates the position of the foot with dorsiflexion signalled by a depression of the trace. Five degrees between starting position and full dorsiflexion. Lower three traces are surface electromyograms each beginning with a calibration mark of 500 μV. Record shows a short voluntary contraction of the triceps suræ which is followed several seconds later by passive dorsiflexion of the foot. Note the lack of electromyographic response of the triceps suræ to dorsiflexion of the foot in the relaxed subject

B, Recordings made immediately following *A*. After a preliminary voluntary contraction of the triceps suræ (at left) a Jendrassik manœuvre is begun, signalled by the electromyogram of the extensors of the right wrist. During the Jendrassik manœuvre the foot is again passively dorsiflexed. Electromyographic activity begins in the triceps suræ as soon as the dorsiflexion of the foot starts and continues with diminishing intensity after the end of the Jendrassik manœuvre until the foot is rotated back towards the initial position. There is no activity recorded from the tibialis anterior
Time marker, 10 sec

record from the calf muscles and continued after the end of the movement while the foot was held steady in the dorsiflexed position. Provided the Jendrassik manœuvre was maintained at an approximately constant level the activity of the calf muscles could be interrupted by rotating the foot back towards the neutral position and would begin again in response to a second dorsiflexion. If the Jendrassik manœuvre was discontinued while the foot was held in the dorsiflexed position the activity of the calf muscles declined, in some cases abruptly and in some cases over a period of several seconds until eventually the muscles showed no action potentials.

There was no activity of the tibialis anterior during the movement of dorsiflexion of the foot. Fig. 1 shows a typical series of recordings during passive dorsiflexion of the foot in the relaxed subject and during the performance of the Jendrassik manœuvre. The apparatus used for rotating the foot about the ankle joint was virtually silent and was placed outside the subjects' field of view. There was no way for them to tell which among the many Jendrassik manœuvres they performed would be combined with the movement of the foot and no way of telling at what moment during any manœuvre the dorsiflexion of the foot would begin. When questioned about the activity of their leg muscles they were generally quite unaware, at least during the first experiment, that any muscle contraction had occurred apart from the voluntary contraction of the arm muscles. Often they did not realize that their foot had been moved. A similar tonic response to muscle stretch could also be evoked from the calf muscles during the performance of a Jendrassik manœuvre by holding the foot still and pressing firmly and steadily on the Achilles tendon just behind the ankle joint. Presumably in this case as with the dorsiflexion of the foot the essential stimulus was the elongation of the calf muscles. Pinching the tendon between the fingers without pulling on the tricep suræ muscles did not cause any activity. The antagonistic tibialis anterior muscle remained without recordable electrical activity throughout the manipulations.

After a passive dorsiflexion of the foot to which there was no active response it was noticed that succeeding manœuvres of dorsiflexion tended to be less effective than usual in evoking a contraction of the calf muscles. Provided the subject lay quite relaxed this apparent increase in the threshold of the stretch response would last indefinitely. Responsiveness to stretch could be immediately restored by either a short voluntary contraction of the calf muscles or by a prolonged and intense Jendrassik manœuvre. In subjects showing this effect strongly each passive dorsiflexion of the foot was preceded by either a short contraction of the calf muscles (as in Fig. 1) or by a standard number of cycles of dorsiflexion and release of the foot. When this was done it became clear that the electromyographic response of the calf muscles to slow stretch was highly dependent on the vigour with which the subjects performed the accompanying Jendrassik manœuvre. Relatively sparse activity of the arm muscles was associated with no stretch response of the calf muscles or perhaps with a response which was delayed until the movement of dorsiflexion of the foot neared completion. Increasingly intense electromyograms from the arm muscles led to stronger calf muscle responses appearing progressively earlier in the dorsiflexion of the foot until action potentials could be recorded while the foot was held stationary in the neutral position. Passive dorsiflexion would then cause an abrupt increase in activity.

The contraction of the calf muscles in response to dorsiflexion of the foot is probably dependent on the monosynaptic segmental stretch reflex arc. No measurements of latency could be made to a satisfactory degree of accuracy, but under suitable conditions the muscle contraction begins with very little delay once the dorsiflexion of the foot begins, and it ceases in a dead-beat manner when the foot is passively plantar flexed. Contraction is restricted to muscles stretched by dorsiflexion of the foot and occurs in response to stretch applied directly through the tendon of the triceps suræ with no movement of the ankle joint. The appearance of a response to slow muscle stretch during the Jendrassik manœuvre is thus thought to depend on the same mechanism of activation of γ-motoneurones as accounts for the increase in the amplitude of the tendon jerks. γ-Motoneurone activity brought about in this manner therefore appears to affect both the dynamic and static sensitivities of the muscle spindle receptors responsible for the afferent impulses generated by both fast and slow stretch.

The very long-lasting increase in stretch reflex threshold that follows a passive muscle stretch which does not evoke any active response is similar to a phenomenon encountered in experiments on human subjects by Hugon and Paillard[8]. They noticed that passive dorsiflexion and release of the foot would greatly reduce the amplitude of the ankle jerks and that reflex responsiveness was not restored until the subjects voluntarily contracted the calf muscles or performed a vigorous Jendrassik manœuvre. The explanation they offered was that passive stretch

produces a deformation of either the muscle spindle or of its linkage with the body of the muscle, and this persists after release when the rest of the muscle tends to regain its original length. Subsequent stretches would therefore need to be more extensive to have the same effect on the receptor endings. Re-setting the receptors after deformation is presumably brought about by contraction of the intrafusal muscle fibres which occurs in isolation in the Jendrassik manœuvre or in conjunction with the contraction of the extrafusal fibres in a voluntary innervation of the stretched muscle.

It was also noticed quite frequently that once the contraction of the triceps suræ was established by the combination of passive dorsiflexion of the foot and the Jendrassik manœuvre, the electromyographic activity would continue for an appreciable time, perhaps many seconds after the Jendrassik manœuvre was interrupted. Since the appearance of tonic stretch reflexes probably depends on the activation of the γ-motoneurones, this observation may mean either that γ-motoneurone discharge produces long-lasting changes in the sensitivity of the muscle spindle endings, or that γ-motoneurone discharge may outlast the Jendrassik manœuvre. It is not unlikely that in intrafusal muscle fibres contraction and relaxation are slower processes than those in extrafusal fibres. However, such differences could only be inferred if the intensity of γ-motoneurone activity was accurately measured, and this was certainly not possible in these experiments. Investigations of tendon jerks have shown that fluctuations in reflex excitability due to changes in γ-motoneurone activity are correlated with many subjective and environmental factors in addition to the well-known effect of voluntary muscle contraction[9]. The electromyogram of the arm muscles provides a guide to only one of the mechanisms which may influence the discharge of the lumbo-sacral γ-motoneurones; we have no sure way of ruling out fluctuations dependent on other factors. Nevertheless, a fairly constant relationship was seen between the intensity of the electromyographic record of contraction of the wrist extensors and the intensity (as opposed to the duration) of the stretch response of the calf muscles. A similar experiment using the tendon jerks was reported by Courts[10], who showed that the amplitude of the knee jerk varied in proportion to the weight that subjects supported by steady contraction of the arm muscles.

The graded sensitization of the stretch reflex of the triceps suræ muscles accompanying voluntary contraction of the arm muscles is probably part of an important mechanism involved in the organization of movement in man. If a similar sensitization of stretch reflexes occurs in other limb muscles the overall effect would be to stabilize the position of the limb in space by tending to fix the length of the muscles. This would be done in a very efficient way, for active muscle contraction would be automatically concentrated in muscles which, in any body position, were those subjected to stretch. The threshold of the stretch reflexes and therefore the degree of stability of the limbs would vary with the intensity of the contraction of the arm muscles. Delicate manipulations involving minimal effort would scarcely alter the stretch reflex threshold whereas a massive mobilization of the arm musculature for lifting heavy weights or for pushing or prising large objects would automatically be accompanied by such fixation of the lower limbs as would be necessary for the effective execution of the movement.

In normal intact man it is usually difficult to distinguish the contribution of simple reflexes to overall behaviour because of the complexity of most movements and the complicated nature of the stimuli that evoke them. The experimental situation used here is of particular interest because it allows the demonstration of one function of the stretch reflex in comparative isolation, making it possible to infer what part this mechanism is likely to play in the control of posture and movement in other circumstances.

I thank Prof. J. Paillard for providing the facilities, support and discussion in connexion with this work.

DISTRIBUTION OF ALLOTYPIC SPECIFICITIES AMONG RABBIT γ-GLOBULIN MOLECULES GENETICALLY DEFINED AT TWO LOCI

By Dr. SHELDON DRAY and GLENDOWLYN O. YOUNG

THE 7*S* γ-globulins of individual rabbits are antigenic for other rabbits and yield precipitating antibodies[1–3]. These isoantibodies identify antigenic specificities on the γ-globulin molecules in the sera of some, but not all, rabbits. Such antigenic specificities are called allotypic specificities and distinguish among 7*S* γ-globulins not thus far separable by chemical criteria. The allotypic specificities A1, A2 and A3 appear to be controlled by three allelic genes at one locus, *a*; the allotypic specificities A4, A5 and A6, by three allelic genes at a second locus, *b* (refs. 4–10). These two loci, *a* and *b*, are not closely linked[10]. Agar-gel tube analysis of sera from individual rabbits indicated that the non-allelic controlled Aa1 and Ab6 are found on the same molecule whereas the allelic controlled Aa1 and Aa3 were on different molecules[11].

A method for quantitative analysis of allotypes based on successive precipitations of specific allotype from ^{131}I-labelled 7*S* γ-globulins with anti-allotype sera was developed[12]. This method was used to study the contribution of allelic genes $A\frac{4}{b}$ and $A\frac{5}{b}$ to the formation of 7*S* γ-globulins in homozygous and heterozygous rabbits[12]. It was found that in homozygotes or heterozygotes, 80–90 per cent of the γ-globulin molecules have Ab4 or Ab5; 10–20 per cent of the γ-globulin molecules lacked Ab4 and Ab5. In the heterozygote, the quantities of molecules precipitated by anti-Ab4 or anti-Ab5 were

lependent of the order of precipitation, indicating that ›4 and Ab5 are not found on the same γ-globulin mole-ıles but only on separate molecules. In two hetero-ygotes, 64 and 66 per cent of the γ-globulin labelled with iodine-131 was precipitated by anti-Ab4 and 27 and 24 per cent by Anti-Ab5.

This article presents a study of the contribution of genes at two loci to the formation of 7*S* γ-globulin molecules, by the quantitative analysis for allotypes[12] and by agar gel investigations[2,13].

In brief, the quantitative method[12] consisted in labelling a purified preparation of γ-globulin (ref. 14) with iodine-131 (ref. 15) and determining the amount of label precipitable by monospecific anti-allotype sera. The γ-globulin preparations used give a single precipitin line by immuno-electrophoresis with a sheep anti-rabbit serum which has precipitins to several β-globulins (including β_2A) as well as to γ-globulins. More than 97 per cent of the radio-activity in each preparation was precipitated by a sheep antiserum monospecific for rabbit γ-globulin; more than 99 per cent was precipitated by trichloroacetic acid (5 per cent).

Although the reactions with anti-allotype sera are carried out in the region of antibody excess, unlabelled carrier γ-globulin together with additional antibody are added to a portion of the supernatant to ensure complete precipitation. Depending on the particular antiserum, 2–4 successive precipitations are necessary to remove completely the corresponding allotype. After complete precipitation of one allotype, small aliquots of the super-natant can be analysed in the same manner with anti-allotypic antibodies of different specificities. To achieve uniform conditions for successive precipitations, only a portion of each supernatant is used. To this is added unlabelled carrier γ-globulin of the appropriate allotypic specificity and additional antiserum. The amount of antigen and antibody present is nearly the same in successive precipitations and the volume is held to less than 1 ml. Mixtures are allowed to stand in the refriger-ator for 1 day (anti-Ab4 and anti-Ab5) or 2 days (anti-Aa1). The percentage of the radioactivity precipitated in the successive steps is used to calculate the amount of γ-globulin of a particular allotypic specificity that was initially present[12].

Fig. 1 is a photograph of an Ouchterlony experiment which compares the reactions of anti-Ab5 and anti-Aa1 with serum of an Aa1, Ab5 double homozygote as well as with a mixture of two sera obtained from Aa1, Ab4

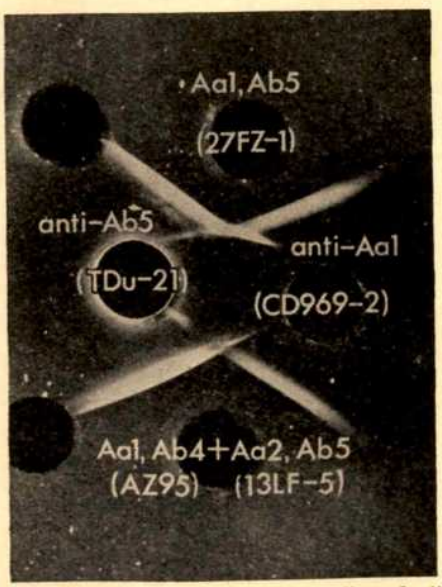

Fig. 1. Ouchterlony experiment comparing reactions of anti-Aa1 and anti-Ab5 with sera from an Aa1, Ab5 double homozygote and with the mixture of two sera from Aa1, Ab4 and Aa2, Ab5 double homozygotes

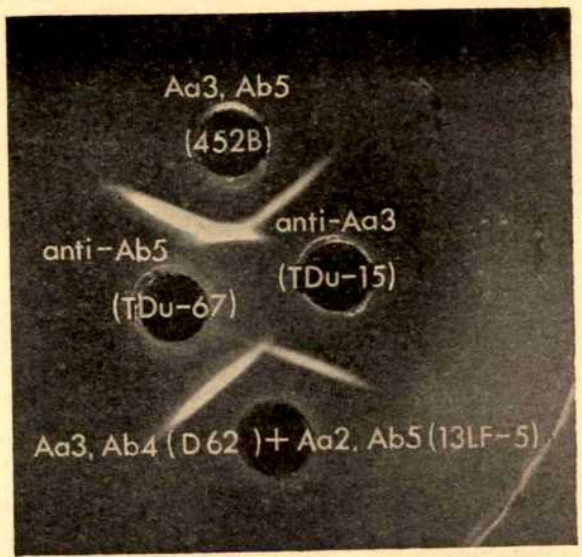

Fig. 2. Ouchterlony experiment comparing reactions of anti-Aa3 and anti-Ab5 with sera from an Aa3, Ab5 double homozygote and with mixture of two sera from Aa3, Ab4 and Aa2, Ab5 double homozygotes

and Aa2, Ab5 double homozygotes. In the mixture of the two sera, Aa1 and Ab5 are *a priori* not on the same molecules; the agar-gel plate accordingly shows a typical reaction of non-identity as expected for antisera which do not cross-react. The reaction of anti-Ab5 and anti-Aa1 with the serum of an Aa1, Ab5 double homozygote is quite different; there is partial coalescence and double spur formation, indicating that Aa1 and Ab5 are on separate molecules as well as on the same molecules. This hypothesis is supported by quantitative precipitin data, which are discussed later.

Fig. 2 shows a similar experiment comparing the reactions of anti-Aa3 and anti-Ab5 with the serum of an Aa3, Ab5 double homozygote as well as with a mixture of two sera from Aa3, Ab4 and Aa2, Ab5 double homozygotes. Again, the artificial mixture gives a typical reaction of non-identity whereas the serum of the Aa3, Ab5 double homozygote gives a reaction of partial coalescence and double spur formation. This suggests that some molecules have either the Aa3 or Ab5 specificity while others have both.

The γ-globulin preparations, when substituted for the sera of the double homozygotes (27FZ–1 and 452B) in the Ouchterlony experiments of Figs. 1 and 2, also showed the same result of partial coalescence and double spur formation in accordance with the idea that the reactions shown are due to the γ-globulins in the sera.

In previous work[12], quantitative analysis for Ab4 and Ab5 yielded the following results: (1) in the double homozygote (31FZ–2) 82 per cent of the γ-globulin labelled with iodine-131 was precipitable by anti-Ab5; (2) in the double heterozygote (20FZ–2), 64 per cent of the labelled γ-globulin was precipitable by anti-Ab4 and 27 per cent by anti-Ab5.

Fig. 3 shows the results of quantitative analysis for Aa1 in 7*S* γ-globulin from the same Aa1, Ab5 double homo-zygote (31FZ–2, top curve) and the same Aa1–Aa3, Ab4–Ab5 double heterozygote (20FZ–2). Four pre-cipitations with anti-Aa1 removed 66 per cent of the labelled γ-globulin from the double homozygote (31FZ–2) and 38 per cent from the double heterozygote (20FZ–2). After precipitation from the double heterozygote of Ab5 (27 per cent of the molecules), 32 per cent of labelled γ-globulin was then precipitable by anti-Aa1. After precipitation from the double heterozygote of Ab4 (64 per cent of the molecules) only 12 per cent of the γ-globulin labelled with iodine-131 was precipitable by anti-Aa1 (as compared with 38 per cent when the anti-Aa1 was used first). In each case the percentages given are based on

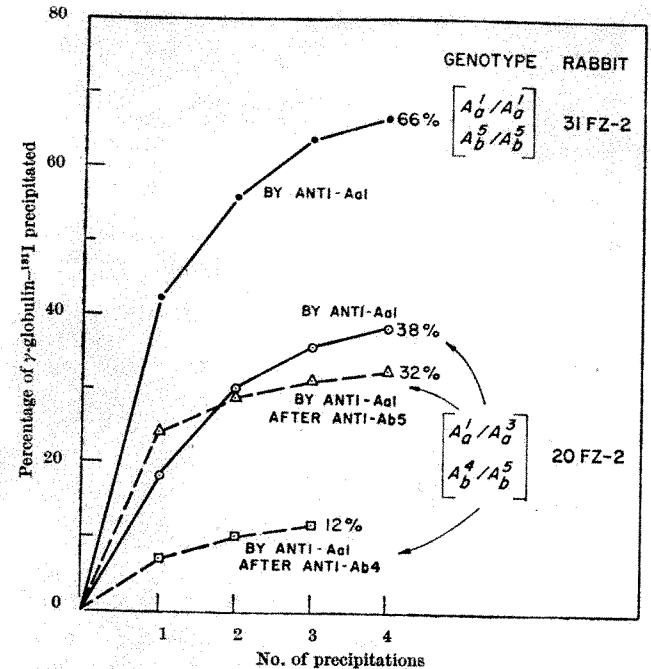

Fig. 3. Quantitative analysis of purified γ-globulin from two rabbits for the amount precipitable by anti-Aa1

the total amount of protein originally present. Three or four precipitations were necessary before the removal of Aa1 approached completion in contrast to the two precipitations generally sufficient for removal of Ab4 or Ab5. This suggests that Aa1 is a 'weak' antigen, perhaps due to an insufficiency of antigenic sites and/or that the amount precipitable may depend to some extent on the antibody preparation used[16].

Since, in the double homozygote, 66 per cent of the labelled γ-globulin is precipitated by anti-Aa1 and 82 per cent by anti-Ab5 (ref. 12), at least 48 per cent (66–18 per cent) of the radioactivity must be associated with molecules having both specificities Aa1 and Ab5. In another experiment (not shown) after precipitation of Ab5 (82 per cent of the molecules), 7 per cent was precipitable by anti-Aa1. Thus at least 7 per cent of the molecules have Aa1 but not Ab5 in accord with the Ouchterlony analysis shown in Fig. 1. In another Aa1–Ab5 double homozygote, 35FZ–1, 17·8 per cent of the labelled γ-globulin was precipitable by anti-Aa1 after removal of 70·3 per cent of the radioactivity by anti-Ab5, confirming the existence of Aa1 molecules lacking the Ab5 specificity (by the criteria of precipitation).

It had been shown previously[12] that in the heterozygote Ab4 and Ab5 are on separate molecules, and that 91 per cent of the molecules have one or the other specificity. Therefore, at least 29 per cent (38–9 per cent) of the radioactivity must be associated with molecules having two specificities, Aa1 plus either Ab4 or Ab5. In the double heterozygote, precipitation by anti-Ab5 reduced the amount of Aa1 from 38 to 32 per cent of the total, whereas precipitation by anti-Ab4 reduced the amount of Aa1 from 38 to 12 per cent. This indicates that 68 per cent (26/38) of the molecules with Aa1 also have Ab4 specificity and that 16 per cent (6/38) of the molecules with Aa1 also have Ab5. If the results presented in Fig. 1 were consistent with completely random association of the non-allelic specificities, then the fraction of Aa1 molecules associated with Ab4 would be the same as the fraction of Ab4 molecules in the total population (64 per cent). The actual value observed was 68 per cent. In the case of association of Aa1 with Ab5, the predicted and observed values were 27 and 16 per cent. However, the value of 16 per cent is sensitive to small errors in percentages of Aa1 observed before and after removal of Ab5. It is of particular interest that the Aa1 and Ab5 specificities were under control of genes derived from different parents. Thus, the molecules in the double heterozygote which have both Aa1 and Ab4 are γ-globulins which are present in neither parent. That such hybrid protein molecules have antigenic specificities (or other properties) differing from the γ-globulins in either parent is suggested also by the work of Oudin[16].

It is of interest to compare the relationship of genetic control of the biosynthesis of γ-globulin to that of hæmoglobin[17,18]. So far, the results obtained for γ-globulin are consistent with those obtained for hæmoglobin. Allelic genes for γ-globulin, as well as for hæmoglobin, do not contribute to the same molecules, whereas non-allelic genes do contribute to the same molecules. Moreover, allelic genes function in the same cell to produce two forms of hæmoglobin. For the γ-globulin, the evidence obtained also indicates that allelic genes function within the same cell to produce two varieties of γ-globulin[19]. It is of interest to note that analogous studies of mucopolysaccharide molecules for human blood group specificities yield somewhat different results: the A and B specificities determined by allelic genes as well as the A and Le specificities determined by genes at two loci appear on the same mucopolysaccharide molecule[20]. Incorporation of the antigenic specificities into the mucopolysaccharide molecule is considered to occur late in its biosynthesis and to be a result of enzyme action rather than a result of primary gene action[20].

Since the facts obtained so far for γ-globulin are in accordance with those for hæmoglobin[17,18] with respect to the contribution of allelic genes[11,12], we suggested[12] that in the double heterozygote, polypeptide chains carrying the Ab4 specificity form pairs immediately after synthesis and that the Ab4 pairs do not combine with similarly formed Ab5 pairs but do combine with pairs of polypeptide chains the synthesis of which is controlled by genes at the a locus, such as by $A\frac{1.}{a}$. This hypothesis further suggests the possibility that the structural model of γ-globulin may differ from that proposed by Porter[21] in that the B-chains as well as the A-chains may exist within the molecule as dimers similar to the α- and β-chains of hæmoglobin. A distinction between γ-globulin and hæmoglobin would be the importance of disulphide bonds in holding together polypeptide chains in γ-globulin. Chemical investigations are needed to evaluate this hypothesis.

If we assume that the synthesis of polypeptide chains and their interaction to form the completed γ-globulin molecule occurs within a single cell, then the foregoing findings lead to the conclusion that in a double heterozygote such as 20FZ–2 (Aa1–Aa3, Ab4–Ab5), at least four allotypes of γ-globulin molecules are synthesized within the same cell; these allotypes are A–a1–b4, A–a1–b5, A–a3–b4 and A–a3–b5. Also, since the parents were Aa1, Ab5 and Aa3, Ab4 double homozygotes, then the A–a1–b5 molecules correspond to those in one parent, the A–a3–b4 molecules to those in the other parent, and finally the other two allotypes A–a1–b4 and A–a3–b5 are hybrids present only in the offspring but not in either parent.

Since more than one allotypic specificity, that is, Ab5, Ab5′ (refs. 4 and 10), is 'functionally' determined by a single allele, that is, $A\frac{5}{b}$, and since the number of genetic loci involved in γ-globulin synthesis is at least three[10], the number of allotypes synthesized within a single cell in a double heterozygote is likely to be much more than four. The question then arises as to the relationship (if any) of this information to the number of antibodies of different specificities formed within single cells[22,23]. Work is continuing to determine the extent of the variation of γ-globulin molecules (number of allotypes) synthesized within a single cell.

In conclusion, the results presented in this article show that genes at the two loci *a* and *b* contribute to the synthesis of the same γ-globulin molecules but not to all of them. Thus, in the Aa1–Ab5 double homozygote there are at least four kinds of γ-globulin molecules: (1) those with Aa1 not precipitable by anti-Ab5; (2) those with Ab5 not precipitable by anti-Aa1; (3) those with both Aa1 and Ab5; (4) those not precipitable by either anti-Aa1 or anti-Ab5. The explanation of this distribution of allotypic specificities among γ-globulin molecules must lie partly in the fact that additional loci are involved in the control of γ-globulins. For example, it is now known that allotypic specificity *P* (ref. 10) is present in each of the γ-globulin preparations analysed and its distribution among the γ-globulins is under investigation.

Finally, in the Aa1–Aa3, Ab4–Ab5 double heterozygote, the polypeptide chains carrying the Aa1 specificity associate with polypeptide chains carrying either Ab4 or Ab5. About two-thirds of the molecules with Aa1 also had the Ab4 specificity even though the genes controlling these specificities came from different parents. Thus, these A–a1–b4 molecules present in the offspring are not present in either parent. The quantities of A–a1–b4 and A–a1–b5 molecules found are consistent with the possibility that the assortment of polypeptide chains under control of the two loci is random, that is, that the fraction of Aa1 molecules also bearing the Ab4 or Ab5 specificity is equal to the fraction of molecules with Ab4 or Ab5, respectively, in the total population[24].

EFFECT OF STARVATION ON ADENOSINE TRIPHOSPHATE CONCENTRATION IN *AEROBACTER AEROGENES*

By R. E. STRANGE, H. E. WADE and F. A. DARK

Microbiological Research Establishment, Porton, Salisbury, Wilts.

WHEN washed stationary phase *Aerobacter aerogenes* are starved in aerated phosphate–saline buffer, *p*H 6·5 (about 10^{10} bacteria/ml.), the viability remains high (90–98 per cent) for at least 40 h (ref. 1). During this period, degradation of endogenous protein, ribonucleic acid and, if present, glycogen occurs and the products are excreted. Synthesis of various compounds also occurs in starved bacteria, for example, during protein and nucleic acid turnover[2], and many of the reactions involved will require adenosine triphosphate (ATP). Dawes and Ribbons[3] have pointed out that energy will also be utilized by starved bacteria during osmotic regulation and for the maintenance of the intracellular *p*H value. Although ATP will be formed during the metabolism of reserves, the rate of formation is likely to fall as the reserves decline during prolonged starvation. Because the amount of endogenous ATP and the ability to synthesize this compound may be of importance for bacterial survival, we have investigated the effects of starvation on its concentration in *A. aerogenes*.

A. aerogenes, grown in an aerated carbon-limiting mannitol–ammonia–salts medium[1] at *p*H 7·2–7·4, were gathered 0·5 h after growth had ceased and washed twice with phosphate–saline buffer by centrifuging. Suspensions (3–10 × 10^9 cells/ml.) in this buffer (0·11 M NaCl containing K_2HPO_4 + KH_2PO_4 (0·02 M PO_4), *p*H 6·5) were starved in gas wash-bottles with vigorous aeration. Changes in the viability were determined by viable plate counts or a slide culture technique[4].

Extracts were prepared by adding perchloric acid (0·25 ml. of 72 per cent w/v) to bacterial suspensions (5 ml.), allowing each mixture to stand at 20° for 0·5 h and then removing the cell debris by centrifuging. Extraction at 20° rather than at 0°–4° gave more reproducible results for the ATP content and did not cause a significant breakdown of standard ATP. The acid extract was neutralized with 2 N potassium hydroxide solution. Precipitated potassium perchlorate was separated after cooling the mixture to 0° and the clear solution was diluted with water to 10 ml. Neither mechanical disintegration of the bacteria nor their dissolution in potassium hydroxide solution before acid extraction increased the ATP concentration in the extract. Hot water extracts of intact bacteria gave low results due partly to the presence of substances which were inhibitory to the assay.

Adenosine triphosphate was determined with the firefly-luminescence technique[5] using a scintillation counter constructed by our colleague Mr. S. Lovett. Reaction mixtures (4 ml.) contained 0·02 M sodium arsenate buffer (*p*H 7·4), magnesium sulphate (3 mM), sample (0–0·3 μg ATP) and an extract of 2·5 mg firefly tails; luminescence was measured for 0·5 min, starting 1 min after the addition of enzyme, and the response was nearly linear within this range. When testing a series of extracts, standard and blank (no ATP) mixtures were assayed frequently. Perchlorate ions in bacterial extracts inhibited the reaction but interference was small when 0·05 ml. or less of extract was assayed. The separation of ATP from acid extracts by gradient elution from ion-exchange resin[6], followed by ultra-violet absorption measurements or firefly luminescence assay of the appropriate eluates, indicated that direct measurements on extracts were 20–25 per cent high. The loss of added ATP labelled with phosphorus-32 during this fractionation was less than 10 per cent of the quantity applied to the column. Of the various fractions obtained from the extracts, only adenosine-5′-diphosphate,

and deoxyadenosine-5′-triphosphate gave a significant response in the assay and these compounds probably accounted for the discrepancy.

The ATP content of freshly gathered and washed bacteria varied with the oxygen tension and solute concentration of the suspending solution; both anaerobic conditions and high solute concentration markedly reduced the amount of ATP extracted (Fig. 1). Considerably less ATP was found when the acid was added directly to a centrifuged pellet of bacteria rather than to a suspension of the pellet in aerated water or phosphate–saline buffer. Presumably the anaerobic condition of the bacteria in the pellet was responsible for the low ATP concentration since resuspension of the pellet in de-aerated buffer did not increase the ATP content. The synthesis of ATP which occurred when the bacteria were transferred from anaerobic to aerobic conditions (Fig. 2) or from a solution of high to one of low solute concentration was extremely rapid. The concentrations found in freshly gathered bacteria suspended in phosphate–saline buffer under aerobic and anaerobic conditions by direct assay of acid extracts were 1·6–2·2 and 0·2–0·5 μg of ATP/mg bacterial dry weight, respectively.

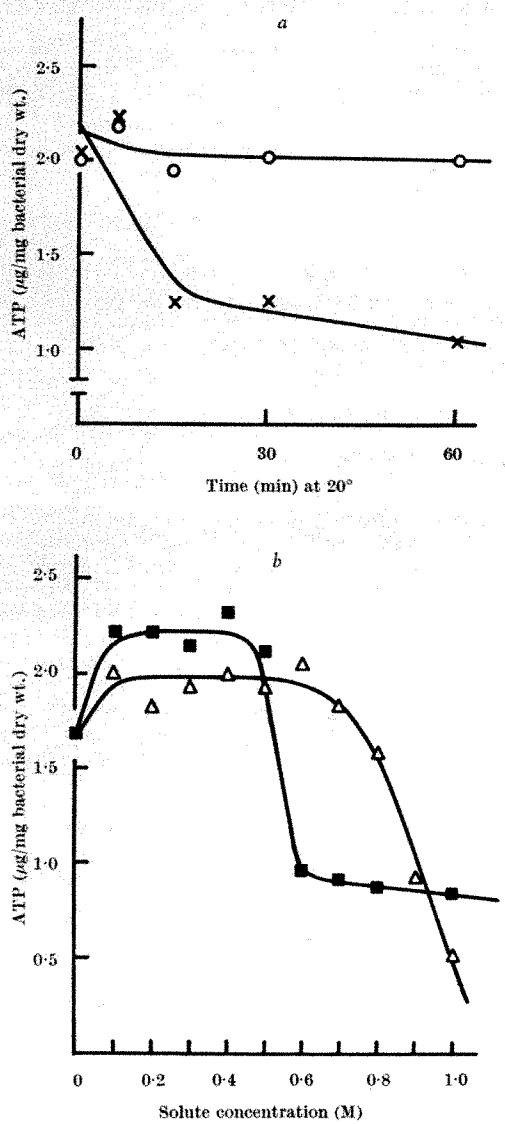

Fig. 1. Effect of oxygen tension and solute concentration of suspending fluid on the ATP content of washed stationary phase *A. aerogenes* (*a*) One portion of an (aerated) bacterial suspension (4·8 mg dry wt./ml.) was aerated (○), and through the other nitrogen was passed (×). Samples taken at intervals from each suspension were acidified and neutralized extracts were prepared for ATP assay. (*b*) Bacteria separated from 5 ml. volumes of a washed suspension (4·1 mg dry wt./ml.) were resuspended in aerated solutions (5 ml.) of various concentrations of sucrose (△) and sodium chlorine (■). After standing for 5 min, acid extracts of the suspensions were prepared for ATP assay

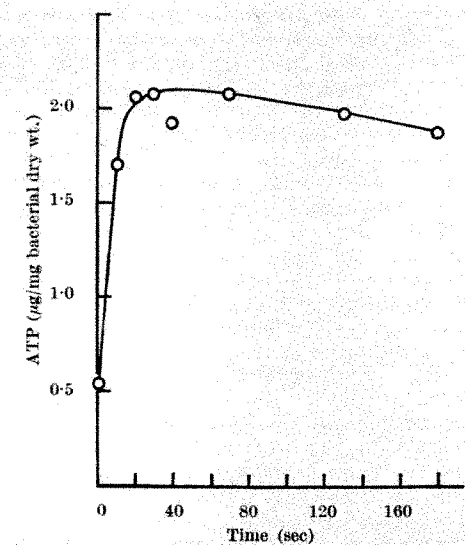

Fig. 2. Synthesis of ATP on transfer of *A. aerogenes* from anaerobic to aerobic conditions. Bacteria separated from 5 ml. volumes of a washed bacterial suspension (4·6 mg dry wt./ml.) were resuspended in 5 ml. of aerated phosphate–saline buffer (*p*H 6·5) and the suspensions were acidified (perchloric acid) at intervals. As a control ($t = 0$) the bacteria were resuspended in acidified phosphate–saline

The analysis of cold perchloric acid extracts of bacteria on ion-exchange resin showed that, although the concentration of ATP was different under aerobic and anaerobic conditions, the total amount of adenosine-5′-mono-, di- and tri-phosphates was the same. For example, the amounts found in 1 g dry weight of bacteria were 1·39, 2·04 and 2·24 μmoles respectively under aerobic conditions and 3·04, 1·81 and 0·8 μmoles respectively under anaerobic conditions. Thus the aeration of an anaerobic suspension causes a regeneration of ATP at the expense of adenosine-5′-phosphate. The concentration of ATP found in this experiment under aerobic conditions was lower than usual, probably because air was passed into a very thick suspension and aeration was not complete. Nevertheless, the value obtained is similar to that reported by Franzen and Binkley[7] for exponentially growing *Escherichia coli*. Using ion-exchange fractionation, these authors found the relative amounts of adenosine-5′-mono-, di- and triphosphates to be about 1 : 5 : 50. These ratios, which were very similar in *E. coli* gathered from six different growth media, are very different from our ratios for stationary phase *A. aerogenes*. However, the relative amounts of these compounds in bacteria appear to vary widely: Kuriki and Okazaki (ref. 8, Fig. 1) showed a high ratio of adenosine-5′-phosphate to ATP in an acid extract from exponentially growing *E. coli* strain 15*T*⁻ (thymine requiring mutant), and Smith and Wheat[9] reported a high ratio of adenosine-5′-phosphate to adenosine-5′-diphosphate in an acid extract from *Chromobacterium violaceum* (NCTC 7917).

The effects of starvation on the ATP content and viability of *A. aerogenes* in aerated phosphate–saline buffer were investigated at 20°, 37° and 44° (Fig. 3). At 20° both viability and ATP remained fairly constant for 55 h; at 37° there was a small initial increase in ATP after which the level fell to less than the initial value before there was a significant loss in viability; at 44° there was a pronounced initial increase in ATP after which the level fell with the viability. The degradation of ribonucleic acid, accompanied by a leakage of ultra-violet-absorbing substances, also increased rapidly with temperature in the range 20°–50°; the initial increase in ATP at the higher temperatures may therefore be due to a synthesis of ATP from adenosine-5′-phosphate or adenosine-5′-di-

phosphate liberated from ribosomes by autodegradation[10] or by some other route which is stimulated by higher temperatures.

Although no direct relationship was found to exist between ATP concentration and viability or survival prospects of a bacterial population, we obtained some evidence to suggest that the ability of bacteria to synthesize ATP in the absence of exogenous nutrient is related to survival. Starvation progressively reduced the magnitude of the increase in ATP which occurs when bacteria are transferred from anaerobic to aerobic conditions; after starvation at 37° for 42 h when viability was 85 per cent, there was no increase when this transfer was made and from then on there was a progressive loss of viability (Fig. 4). Similarly, during starvation at 37° in aerated M sodium chloride the ability of bacteria to synthesize ATP on transfer to aerated 0·15 M sodium chloride declined at a faster rate than viability (Fig. 5). After 4 h, loss in viability was 10 per cent and the amount of ATP synthesized on transfer of the bacteria was less than 50 per cent of the 2-h value; after 18 h loss in viability was 92 per cent, and no ATP was synthesized on transfer of the bacteria. The results obtained for bacteria starved in 0·15 M sodium chloride are also shown (Fig. 5).

These results indicate that the ATP concentration in non-growing *A. aerogenes* depends largely on the oxygen tension and solute concentration of the environment and is not necessarily related to the viability or the survival prospects of a population. Starvation eventually reduces both the ATP concentration and the ability of the bacteria to synthesize ATP when transferred from anaerobic to aerobic conditions or from solutions of high to those of low solute concentrations.

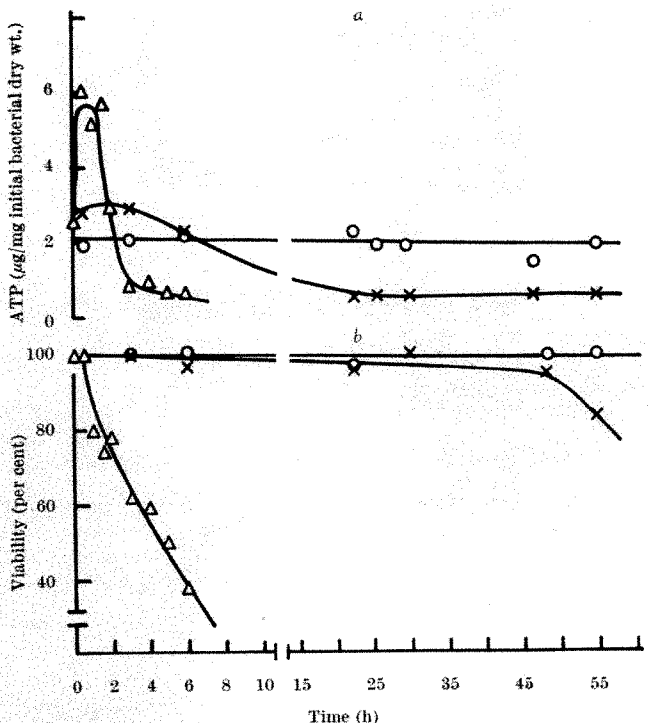

Fig. 3. Effect of starvation on the ATP concentration and viability of *A. aerogenes*. Portions of a washed suspension of stationary phase bacteria (4 × 10⁹/ml.) were held at 20° (○), 37° (×) and 44° (△) in aerated phosphate–saline buffer and samples removed at intervals for (*a*) ATP and (*b*) viability determinations

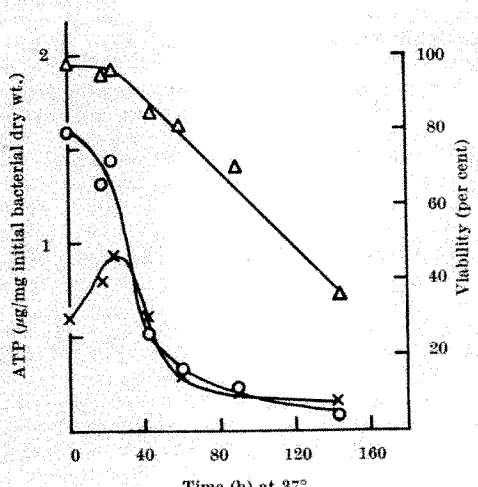

Fig. 4. Effect of starvation on the ability of *A. aerogenes* to synthesize ATP. A washed, aerated suspension of bacteria (4 × 10⁹/ml.) in phosphate–saline was held at 37° and duplicate samples (5 ml.) were removed at intervals. Both samples were centrifuged and the pellet from one resuspended in 5 ml. of 0·5 N perchloric acid (anaerobic, ×); the other pellet was resuspended in aerated phosphate–saline and the suspension acidified after 5 min (aerobic, ○). Extracts were prepared and assayed for ATP. Viability of suspension (△)

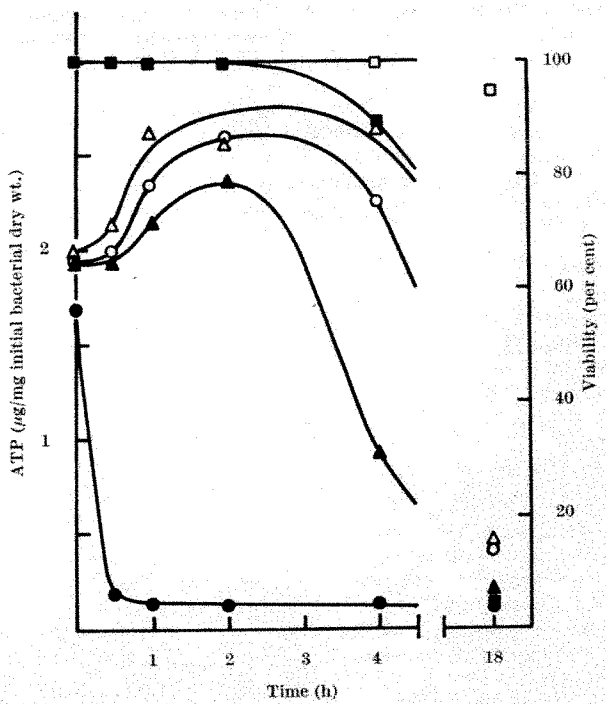

Fig. 5. Effect of starvation in solutions of high and low solute concentration on the ability of *A. aerogenes* to synthesize ATP. Suspensions of washed bacteria (7 × 10⁹/ml.) in 0·15 M sodium chloride (open symbols) and M sodium chloride (closed symbols) were aerated at 37°. Duplicate samples (5 ml.) were removed at intervals from each suspension and one of each pair was acidified directly (○, ●), while the other was centrifuged and the pellet resuspended in aerated 0·15 M sodium chloride before acidifying (△, ▲). Extracts were prepared for ATP assay. Viability of suspensions (□, ■)

LETTERS TO THE EDITOR

PHYSICS

Liquid Explosives with Transparent Detonation Products

In an attempt to observe events behind the shock front of detonating explosives we have investigated the possibility of finding materials having transparent reaction products. Explosives of this sort might then simplify the problems since visible light photography could be used instead of X-ray techniques. Preliminary results obtained using a high-speed framing camera have been reported[1] for 18 molal hydrazine mononitrate in hydrazine. This explosive was chosen since it was believed that the opacity commonly observed[2] in detonation gases was due to free carbon. The reaction products of this carbon-free explosive transmitted light, and strong turbulent patterns could be seen. We can now present evidence showing that explosives containing carbon, specifically mixtures of nitromethane and tetranitromethane, can also have transparent products.

An observation container for liquid explosives was made by cementing thin aluminium ribs between two opposite edges of a pair of $6 \times 6 \times 1\frac{1}{2}$ in. 'Plexiglas' blocks. A 1/8-in. aluminium plate was cemented over one of the open ends, forming a tank open on one side and having an internal thickness equal to the thickness of the metal ribs. The cameras, either a high-speed framing or rotating-mirror streak type, observed events occurring within the loaded tanks by the use of diffused backlight from an argon flash-bomb. Most of the tests were on explosive sheets $\frac{1}{4}$ in. thick since at this thickness the pure explosive components, nitromethane or tetranitromethane, would initiate but later fade after propagating only part way through the sample. Opacity of the pure explosive reaction products could then be clearly seen since our intense backlight could not penetrate the cloud. The test liquids were line initiated through the 1/8-in. aluminium plate. The streak camera photographs were velocity synchronized, that is, the mirror speed was adjusted to produce a stationary image on the film of the event sweeping past the 0·020-in. camera slit.

Fig. 1 is a framing camera photograph looking through a sheet of nitromethane at the time of failure. Early frames of this event show the detonation proceeding uniformly along a straight line. After a time, roughness develops and at points where failure has occurred the shock wave is detached from the product cloud. The emerging shock wave always has the contour of the product cloud but quickly becomes smooth as it pulls away.

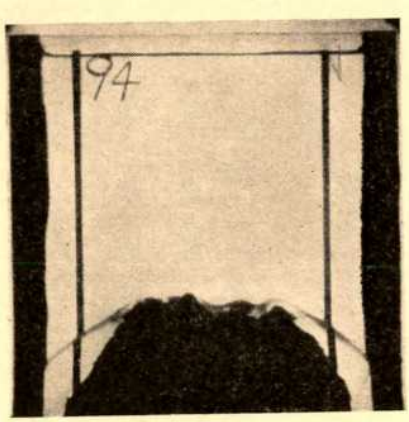

Fig. 1. Framing camera view through a $\frac{1}{4}$-in. thick layer of nitromethane. Exposure time $\frac{1}{4}$ μsec

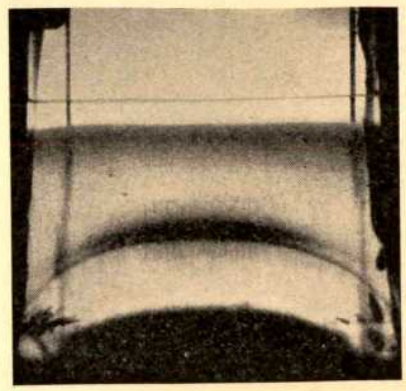

Fig. 2. Framing camera view through a $\frac{1}{4}$-in. layer of detonating nitromethane–tetranitromethane mixture. Exposure time $\frac{1}{4}$ μsec

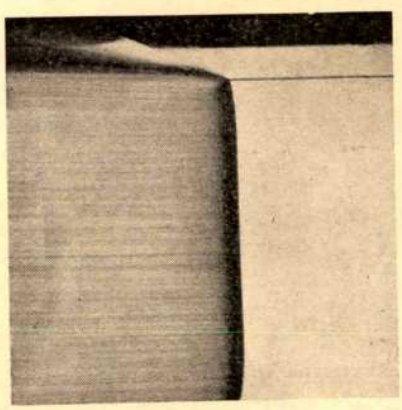

Fig. 3. Streak camera photograph of detonation (left to right) in a nitromethane–tetranitromethane mixture

The two vertical lines which are refracted by the pure shock in the liquid are silhouettes of 1/8-in. wide metal ribbons on the back outside surface of the tank. When such ribbons were placed on the back inside surface, the failing detonation tended to climb them as might be expected. Tetranitromethane at these dimensions shows a somewhat similar failure pattern.

Fig. 2 is a photograph looking through a 1/8-in. sheet of a detonating mixture of 70/30 (by vol.) nitromethane/tetranitromethane. This mixture is sensitive and will easily detonate in 1/32-in. sheets. The two grid lines are visible through the reaction products. The curved arc is due to a shock in the 'Plexiglas' windows from the plane wave booster which overlapped the tank edges. Toward the detonation front some opacity can be seen. In both Figs. 1 and 2 the liquid surface can be seen toward the top of the tank.

Fig. 3 is a streak camera view through an identical 1/8-in. tank filled with 80/20 nitromethane/tetranitromethane. The striations behind the zone are due to turbulence in the gas products[1]. The reaction zone region is abruptly opaque and gradually clears. The air-liquid interface forms a dark horizontal line near the top of the photograph. An air shock followed by a shock in the 'Plexiglas' window can also be seen. The rarefaction at the unconfined interface appears to have produced a region of transparency in the opaque zone and forms an angle of about 45° with the direction of propagation. This opaque zone is roughly twice as long in a 1/4-in. thick tank as in a 1/8-in. one, that is, about $1\frac{1}{4}$ μsec compared with 1/2 μsec.

A 'dark space' of 0·5 sec duration has been observed[3] at the detonation front in pentolite and it was suggested that this was due to a highly ionized region which acted as a reflector and blocked the transmission of internal light. We favour this mechanism to explain the absence of transmitted backlight in our experiments. However, Johansson and Sjölin[2] believe that carbon particles may form a light-absorbing screen at the surface layer of the detonation gas and they have data indicating this as a possibility. Our experiments show that the opaque reaction products from nitromethane, ostensibly free carbon, can be burned to produce clear products if the oxygen balance is adjusted by the addition of tetranitromethane to anywhere within the carbon monoxide–carbon dioxide stoichiometric limits. In line with the Johansson–Sjölin explanation it is of interest to note that self-luminosity is markedly higher in those mixtures having transparent products and reaches a peak within the carbon monoxide–carbon dioxide limits. Detonation luminosity is at its lowest with pure tetranitromethane but in this case, as with oxygen-rich mixtures, the opacity may be due to nitrogen oxides.

Transmission Parameters of Porous Sound Absorbers (with Particular Reference to the Flow Resistance)

Flow resistance, being relatively easy to measure, is commonly used as a rough guide in choosing sound-absorbing materials for specific purposes. This practice is based on the tacit assumption that, when there is an alternating air-flow through the sample, the resistance encountered is identical with the flow resistance. It can be shown, however, that in the case of several materials this assumption is false, and that the acoustical resistance under alternating conditions is substantially greater than the flow resistance.

To establish the variation of effective resistance with frequency the characteristic impedance (Z_0) and the specific transmission constant ($\gamma = \alpha + j\beta$) of a number of commonly used porous sound-absorbing materials have been measured over the range 100–1,300 c/s using samples 1 in.–3 in. thick inserted into a rigid tube 3·47 in. in diameter. At each frequency sound is passed into the sample under two conditions in succession: first, when the sample is terminated by an impedance effectively infinite, and second when the terminal load is purely capacitive. By adopting an electroacoustic artifice the effect of the input impedance of the probe microphones, which measure the sound pressure, is completely eliminated, and by using an a.c. potentiometer to measure microphone voltages, the pressure ratio is derived as a complex number. Assuming that conventional transmission theory is applicable, this ratio is $\cosh(\gamma l)$ (l = sample thickness); whence γl. Knowing γl, the second test yields Z_0 in terms of the terminal capacitance.

After analysing the variation with frequency of these two parameters, it is found that in all the materials examined the series arms of the equivalent-tee network which represents the performance of the acoustical structure contain resistance and inductance in series, the shunt arm being a capacitance in series with a small resistance. Where the test samples have been sufficiently stable to yield very precise data it has been possible to investigate the series arms of the tee network in detail; it is then found that each branch consists of two series combinations of R and L in parallel which have impedances $(R_1 + j\omega L_1)$ and $(R_2 + j\omega L_2)$, L_2, say, being greater than L_1. Re-analysis of the data published in ref. 1 confirms this curious disposition. The same data also confirm the series arrangement of the shunt branch of the tee-network, a fact apparently unrecognized by the authors. It is to be noticed that a later publication[2] discusses the possibility of a rather similar disposition, using arguments of quite a different kind. Yet another publication[3] presents data which on re-analysis confirm the series combination of R and C, in the shunt arm, mentioned here.

If then we assume that the series arm of the equivalent tee-network has the dual form described, with $L_2 > L_1$, it is clear that flow resistance measures the value of R_1 in parallel with R_2, whereas when frequency rises from zero the effective resistance rises towards R_1—a quantity which in various materials has been found to be of the order of 1·5 up to 3 or more times the flow resistance. Moreover, as L_2 may be many times greater than L_1, the frequency at which the transition from the lower to the higher effective resistance is substantially complete may be as low as 150 c/s; usually it is in the region of 200–300 c/s.

Knowing both Z_0 and γ it has been possible to go a stage further and to build electrical artificial lines, the input impedance of which imitates the acoustical impedance, at normal incidence, which sheets of any thickness of the tested materials would present when mounted on the walls of a room as sound absorbers. The real part of the electrical input impedance is—subject to the usual corrections—a measure of the acoustical resistance in which the sound would be absorbed. By modifying the length of the artificial line and its terminal impedance it becomes possible to predict the effect of altering the thickness of the absorber and of its method of mounting.

Dielectric Properties of Cross-linked Polystyrene Film formed in the Glow Discharge

Irradiation of a monomer vapour frequently causes polymerization leading to the formation of a solid deposit on any convenient surface. Electrons[1], ultra-violet, X-, γ-radiation or an electrical discharge[2] can be used.

In the work recorded here. a glow discharge at 180 kc/s is used to form uniform 1μ polystyrene film. The discharge is maintained between parallel cylindrical aluminium electrodes in several mm mercury pressure of styrene vapour contained in a pre-evacuated chamber. Aluminium foil, in contact with one electrode, serves as the substrate for the film. This electrode rotates uniformly during polymerization. Aluminium is afterwards evaporated on to the surface of the polymer film to provide a second electrode.

Fig. 1 shows power factor and capacitance against temperature at several frequencies. The wide distribution of relaxation times, apparent from the shape of the curves, results from the complex structure of the film. Traces of oxygen and water vapour, which give rise to highly polar groups, are especially significant since only milligrams of polymer are formed. Further, electron spin resonance measurements made at room temperature *in vacuo* show the presence of free radicals which presumably peroxidize on exposure to air.

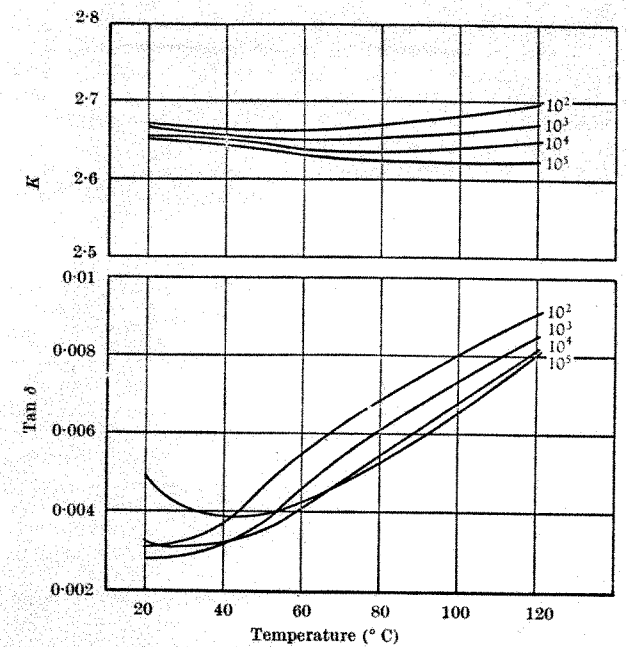

Fig. 1. Permittivity and loss tangent versus temperature at four frequencies

An interesting feature of the films is their insolubility, indicating a high degree of cross-linking. Dipolar loss due to the presence of combined oxygen is evidently spread over a wide frequency range. The frequency/loss angle relationship depends on the flexibility of the polymer chain to which the oxygen is attached. This is greatly restricted in a cross-linked material.

GEOPHYSICS

Tritium Content of Antarctic Snow

The abundance of tritium in Nature is of much geophysical interest[1–3]. In view of the present paucity of data on Antarctic tritium, we are reporting here determinations made on three Antarctic snow samples collected by one of us (H. A. C. N.) during 1960–61.

Three samples of several litres each were collected from the Ross Ice Shelf in the general vicinity of Ross Island (77·5° S., 168° E.). Determinations of tritium were made in August 1962 by a laboratory specializing in low-level tritium assay of geological samples (the tritium laboratory of Isotopes Incorporated, Westwood, New Jersey; we thank M. Trautman for carefully supervising the tritium determinations, for discussions of the techniques used, and for the precautions taken to prevent contamination of the samples by tritium from other sources). The method used was the standard one of electrolytic enrichment of tritium followed by low-level counting[4]. The counting was performed on two portions of each enriched sample, following check-runs using 'blank' (< 10 T.U.) water. One T.U. is an abundance of 1 tritium atom per 10^{18} hydrogen atoms. The results are shown in Table 1 (samples *A*, *B* and *B′*). The third column gives the tritium content extrapolated to the time of precipitation of the snow. The tritium content at the time of assay is given in parentheses in the same column. The errors shown for the values in parentheses are the overall standard deviations of the tritium analyses.

Table 1. Tritium Contents of Antarctic and Southern-Hemisphere Precipitation

Description of sample	Time of precipitation	Tritium content in T.U.*	Ref.
A. Ross Ice Shelf snow, near Cape Crozier; collected early Dec. 1960; top 15 cm	Sept. to Dec. 1960	82 ± 8 (82 ± 8)	This communication
B. Ross Ice Shelf firn, near Scott Base; collected mid-Jan. 1961; 6·6–6·8 m depth	~1941	17 ± 3 (5·2 ± 0·5)	This communication
B′. Ross Ice Shelf ice, near Cape Crozier; collected early Dec. 1960; ~8 m depth (contaminated *in situ*; see text)		– – – – (43 ± 4)	This communication
Antarctic snow; collected Feb. 19, 1955; top 0·3 m; average of 4 samples	1953–54	16 ± 3	Table 2 of ref. 5
Antarctic snow; collected Jan. 15, 1955; 0·3–1 m depth; average of 4 samples	~1952–53	17 ± 3	Table 2 of ref. 5
Antarctic snow; collected Jan. and Mar. 1956; depths covering 5 years; several samples	~1951–55	Little or no artificial tritium (see ref. 6)	Ref. 6
Akatarawa Stream (Wellington, N.Z.) water; yearly average of monthly samples	1956	5·3	Ref. 7
	1957	6·6	Ref. 7
	1958	9·8	Ref. 7
	1960 (May–Sept.)	10	Ref. 7
Average rains in middle and low southern latitudes	1958–mid 1960	~10	Ref. 2

* Values given in parentheses in this column are tritium contents at time of assay; these are preceded by values extrapolated to time of precipitation.

Sample B. This firn sample was collected near the bottom of a glaciological pit 6·8 m deep from a point about 5 cm inside the pit wall. The stratigraphy of the pit walls and of a vertical core taken from below the pit floor shows that this sample represents the snow of approximately the year 1941[8]. The Ross Ice Shelf at this point is 43 m thick, the bottom 28 m of which is soaked by brine from the sea below[8]. The value of 17 T.U. for this single sample is in good agreement with the average of eight shallower Antarctic samples measured by Begemann and Libby[5] and listed in Table 1.

Sample B′. This sample was taken from the side of a deep fissure in the seaward front of the Ross Ice Shelf at a point about 8 m below the Shelf surface. Although some material was removed from the side surface before collecting, the sample very likely had been contaminated *in situ* by seepage of recent precipitation. With this in mind, one sees that its measured tritium content is consistent with those of samples *B* and *A*.

Sample A. This sample, representing the average snow of September–December 1960, has a tritium content five times the level for 1941 as given by sample *B*. For comparison, Table 1 summarizes other published tritium data known to us for southern-hemisphere precipitation after 1956. The doubling of the tritium-level during 1956–60 in New Zealand precipitation (as measured in the fast-flowing waters of Akatarawa Stream) has been ascribed to injection of artificial tritium into the northern-hemisphere stratosphere by thermonuclear explosions[7]. Individual rains at other middle and low southern latitude localities fluctuated considerably around 10 T.U. from 1958 to mid-1960[2], but in no case approached the 82 T.U. measured in sample *A*. It is also likely[9] that much natural tritium was introduced into the north and south polar stratospheres during and following the unusually active 1958 solar maximum, both by local production due to solar cosmic rays and by accretion of solar tritium. However, the global fall-out pattern of artificial strontium-90 introduced at any latitude into the northern-hemisphere stratosphere is strongly peaked in latitudes 30°–60° in both hemispheres[1,9] though the total fall-out is much less in the southern hemisphere. There is evidence that the fall-out mechanism of stratospheric tritium is similar to that of stratospheric strontium-90 (ref. 2). One would then expect the concentration of natural or artificial tritium at the south polar region to be lower (rather than higher) than that at middle southern latitudes. Thus, according to this view, neither artificial nor natural injection of excess tritium into the stratosphere seems to explain the high tritium content of the single sample

reported here. It is conceivable that some special meteorological or hydrological condition was responsible.

One might also consider the possibility of substantially increased tritium porduction in the polar 'troposphere' by the high-energy (> 500 MeV) end of the solar-cosmic-ray spectrum (especially the November, 1960 events just preceding collection of samples). Since the polar tropospheric residence time of tritium is perhaps of the order of weeks only, intense polar fall-out could thus result. However, without knowledge of Antarctic hydrology, no quantitative statement can be made with regard to this possibility. It must be emphasized that the tritium-level given here is based on a single sample (though not on a single snowfall); further Arctic and Antarctic tritium data would be most desirable.

This work was supported in part by the Geophysics Research Directorate, Air Force Cambridge Research Laboratories, Bedford, Massachusetts. One of us (H. A. C. N.) thanks the U.S. Antarctic Research Program and the U.S. Navy for assisting him in collecting the samples.

MINERALOGY

Electron Spin Resonance Spectra in Various Clay Minerals

In the course of studying the mechanism of vinyl polymerization on clay mineral substrates[1] by means of electron spin resonance it became evident that strong electron spin resonance signals were associated with the original clays themselves. A survey of five different montmorillonites, two kaolinites and an illite has shown that this is a general phenomenon.

The electron spin resonance spectra for montmorillonites at room temperature have a single, characteristic, asymmetric peak near the region of free spin ($g = 2{\cdot}00$), as shown in the top trace in Fig. 1 for a sample from Clay Spur, Wyoming (A.P.I., No. 26). In some of the other montmorillonites which we have examined, this characteristic peak is superimposed on multiple peaks from transition metal elements, principally iron and manganese, that are present as impurities in the crystal lattice of the clay mineral. This comparatively narrow signal near the region of free spin we attribute to the presence of appreciable quantities of an organic free radical.

The spectrum for a sample of illite from Fithian, Illinois (A.P.I., No. 35), is shown in the middle trace in Fig. 1, and is seen to be a symmetrical peak near the free spin region.

The two kaolinites yield a different signal, an asymmetrical double peak as shown in the bottom trace in Fig. 1 for a sample from Macon, Georgia (A.P.I., No. 4). This double peak indicates restricted rotation of free radical species with an anisotropic g-value[2]. The sample of vermiculite from Libby, Montana, failed to show any signals other than those attributable to transition metal elements.

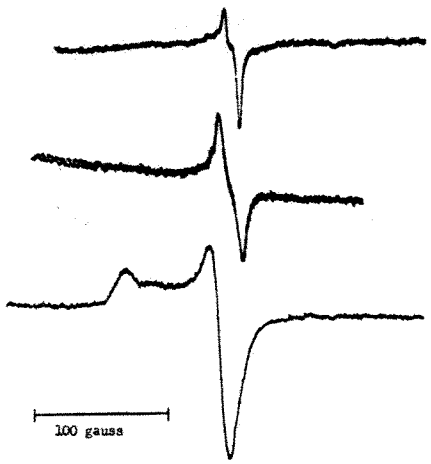

Fig. 1. Characteristic electron spin resonance spectra for clay minerals: top trace, montmorillonite (Clay Spur, Wyo.); middle trace, illite (Fithian, Ill.); bottom trace, kaolinite (Macon, Ga.)

These clay mineral samples which we have examined are all from mineral deposits usually assumed to be substantially free of organic matter. We estimate, by comparison with standardized solutions of DPPH, that the free radical content of these clays is of the order of 10^{16} spins/g. This concentration of free radicals, while large, can be attributed to mere traces of organic matter which are found[3] in most clay deposits. The lack of any organic free radicals in the vermiculite sample may be attributable to the geological nature of vermiculite deposits, which tend to be massive rock-like formations quite impervious to water. The other clay deposits could presumably acquire their organic contaminant by percolation of water-carrying organic matter from surrounding areas.

Identification of these organic free radicals is, as yet, speculative. One is tempted to relate these free radicals to humic acid, which is known to contain free radicals and is adsorbed by clay minerals. Our electron spin resonance spectra for two commercial samples of humic acid (K. and K. Laboratories, New York; Alpco Co., Ione, California) resemble closely those found for humic acid from Alaskan peat[4] and from the *B* horizon of two podzolic soils as well as another commercial sample[5]. All six of these humic acids give an electron spin resonance peak about 7 gauss wide. The clay samples, however, give varying asymmetrical peaks: about 13 gauss for the montmorillonites, and about 24 gauss for the kaolinites and illite. Therefore, we suggest that free radicals are present which cannot be explained in terms of humic acid alone.

Since clay is often added or present in both biological and chemical systems, we deem it important to point out that appreciable and variable concentrations of organic free radicals exist in clay minerals hitherto considered relatively pure. For example, when clays are used in studies of microbial activity at solid–liquid interfaces, the effects are both appreciable and variable, as evidenced by a recent review[6], which cites equal numbers of investigators who have found either stimulation or depression of growth. Similarly, the varying ability of minerals to stabilize soil organic matter[7] is still under investigation. Finally, it seems that the presence of these potentially active organic free radicals should be considered in studies of the reactions of antibiotics in soils[8] and in the present very active investigations of the persistence of herbicides and pesticides[9].

Clays are, of course, used as additives in non-enzymatic systems, and here again we would expect that an organic free radical may play an important part. Catalysis of polymerization[1], a scavenging action for halogens, or interference in any one-electron mode of oxidation or

reduction are among the reactions one might expect from such an impurity. Further work is under way in our laboratories aimed at furthering our knowledge of these potentially reactive materials.

We thank Dr. W. G. Hodgson, Stamford, Connecticut, and Dr. R. G. Wheeler, Yale University, for helpful discussions.

ENGINEERING

Yield Front in the Propagation of Plastic Deformation in Normalized Mild Steel

It is generally accepted that slip occurs in polycrystalline materials along planes subject to the maximum or principal shear stress, inclined at 45° to the principal stress directions. In tensile tests on parallel specimens it has been reported[1] that plastic working advances behind a front inclined at an angle of 35° to the non-zero principal stress. This is not applicable to specimens having varying cross-sectional area where work-hardening appears to occur simultaneously with the progression of a plastic front which has been observed to be normal to the axis of the specimen. In biaxial stress systems plastic working along slip lines has been observed not to be contained within a front[2]. Bijlaard[3] has examined the simple tension case. Using a similar analysis it can be shown that for non-dilatational incremental plastic strains a 'front' exists at 35° to the cross-section behind which deformation can take place to produce zero normal strain along the front. Such deformation would be free from restraint arising from the material ahead of the front, and it is plausible to believe that the propagation of a front and also fracture by necking may be determined by this property.

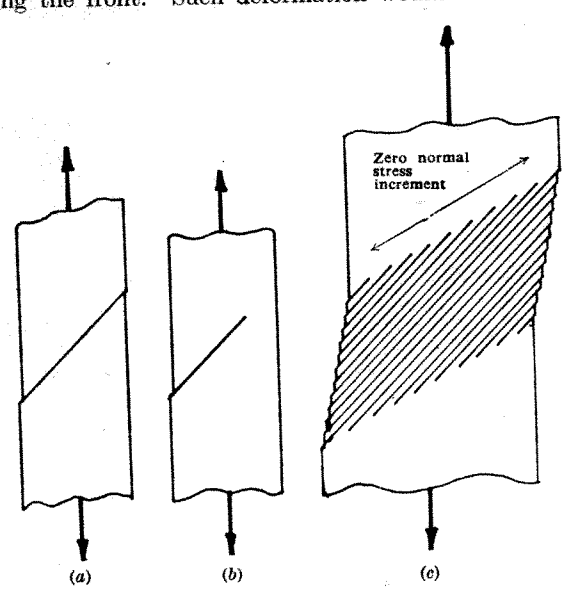

Fig. 1. *a*, Free slip line; *b*, locked slip line with local strain field at head of slip; *c*, stabilized yield front

The plastic strain, however, is produced by a very large number of dislocations, and in a polycrystalline structure these dislocations must occur mostly at 45° to the applied stress. It has been shown that initially slip occurs along the 45° direction, but that as yield continues a well-defined front at 55° to the axis develops. The two effects may be reconciled by a pictorial representation of an idealized slip line and of a system of slip lines. No explanation is offered of the mechanism whereby the front is formed, but it is demonstrated that a front, if formed, would be stable and could propagate.

If these concepts are reconcilable it is necessary to show why in pure shear no such front can exist. Taking principal stresses P, Q, R, with $R = 0$. Suppose $P = -Q$, then for incremental plastic strains the principal strains will be ε and $-\varepsilon$ and the normal strain inclined at an angle β will be:

$$\varepsilon_\beta = \varepsilon \cos^2\beta - \varepsilon \sin^2\beta$$

Thus,

$$\varepsilon_\beta = 0 \text{ when } \cos^2\beta = \sin^2\beta, \text{ or } \beta = 45°$$

There is, therefore, no front behind which principal slip lines can be preferentially arrested.

These effects have been confirmed using strain optically sensitive coating techniques, but further tests are required on other states of biaxial stress.

Effect of Some Organic Additives on Conduction Current and Breakdown of Insulating Liquids

Previous work on the gassing properties of insulating liquids revealed beneficial effects of some organic additives on gassing rate of these liquids[1]. The results presented here show that these additives also affect the conduction current and breakdown voltage of insulating liquids.

Test liquid used was *B*30 transformer oil supplied by Gulf Oil (Great Britain), Ltd., and the additives chosen were: azobenzene, azoxybenzene, diphenyl, benzophenone, benzil, anthracene, naphthaquinone and anthraquinone. The concentrations of additives in solutions varied from $2{\cdot}3 \times 10^{-6}$ to $4{\cdot}59 \times 10^{-3}$ mole/100 g of the basic liquid. Test samples, filtered through a No. 5 sintered glass filter, were carefully degassed (10^{-3} mm mercury) and stress conditioned at about 600 kV/cm, for not less than 2 h, before each test. Spherical nickel electrodes 5 mm in diameter were used in all tests. Conduction current and breakdown voltages were measured for four gap settings, namely: 28, 51, 81 and 125μ, and it was possible to measure the conduction current up to breakdown fields. Reported values of breakdown voltages are mean values of 14 runs.

It was found that all additives used did affect the conduction current and breakdown voltage of transformer oil. For the ranges of concentrations used most additives produced a reduction of conduction current and in general an increase in breakdown voltage. Moreover, the results showed that there was an 'optimum' concentration of the additive which gave maximum reduction of conduction current and another, somewhat higher concentration, which resulted in a maximum increase of breakdown voltage. Exceeding these optimum concentrations produced a smaller reduction in conduction current and the gain in electric strength of the solution became less. For

still higher concentrations even an increase in conduction current and a reduction of breakdown voltage were possible.

Typical results are shown in Fig. 1 for 125μ gap setting. Table 1 gives the optimum concentrations for maximum breakdown voltages and for comparison, also, the concentrations which produced maximum reduction of conduction current.

The beneficial effect of all additives increased with the volume of the solution under stress (gap setting). Additives containing oxygen in their molecular structure gave also a considerable increase of breakdown voltage for small gap settings, an effect which was not observed for other additives, namely: azobenzene, diphenyl and anthracene. Breakdown voltage/gap setting characteristics, given in Fig. 2, show, for solutions containing azoxybenzene,

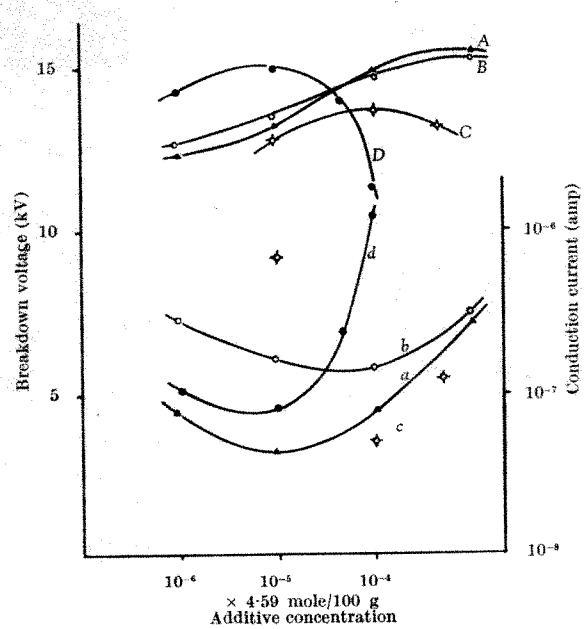

Fig. 1. Breakdown voltage and conduction current in solution as a function of additive concentration for 125μ gap setting. *A*, *B*, *C*, *D*, Breakdown voltage; *a*, *b*, *c*, *d*, conduction current in solutions containing azobenzene, azoxybenzene, benzophenone and benzil respectively. Pure liquid: breakdown voltage, 12·2 kV; conduction current, 0·922 × 10⁻⁶ amp.

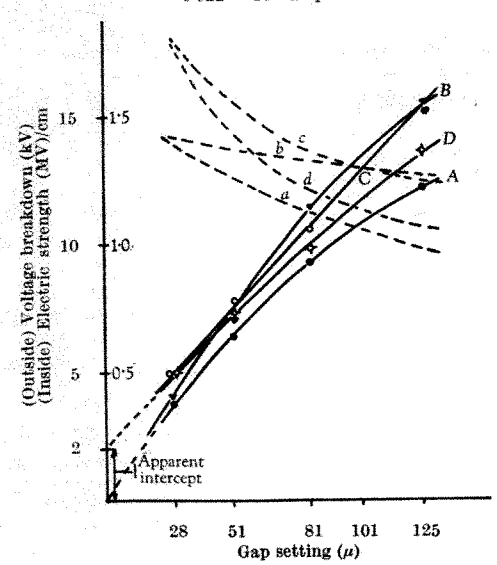

Fig. 2. Breakdown voltage and electric strength of solutions containing various additives as a function of gap setting. Breakdown voltage/gap setting characteristics: *A*, pure transformer oil; *B*, transformer oil + azobenzene, concentration 4·59 × 10⁻³ m/100 g; *C*, transformer oil + azoxybenzene concentration 4·59 × 10⁻³ m/100 g; *D*, transformer oil + benzophenone, concentration 4·59 × 10⁻⁴ m/100 g. *a*, *b*, *c*, *d*, Corresponding electric strength/gap setting characteristics

Table 1. Optimum Concentrations for Maximum Increase of Breakdown Voltage and Maximum Reduction of Conduction Current in Transformer Oil Solutions containing Various Additives

Additive	Optimum concentration (mole/100 g) for: Maximum reduction of conduction current		Maximum increase in breakdown voltage	
	28-μ gap	125-μ gap	28-μ gap	125-μ gap
Azobenzene	$4·59 \times 10^{-4}$	$4·59 \times 10^{-5}$		$4·59 \times 10^{-3}$
Azoxybenzene	$4·59 \times 10^{-6}$	$4·59 \times 10^{-4}$	$4·59 \times 10^{-4}$	$4·59 \times 10^{-3}$
Diphenyl	$2·30 \times 10^{-2}$	$4·59 \times 10^{-3}$		$2·30 \times 10^{-2}$
Benzophenone	$4·59 \times 10^{-5}$	$4·59 \times 10^{-4}$	$4·59 \times 10^{-4}$	$4·59 \times 10^{-4}$
Benzil	$4·59 \times 10^{-6}$	$4·59 \times 10^{-5}$	$4·59 \times 10^{-5}$	$4·59 \times 10^{-5}$
Anthracene	$2·30 \times 10^{-5}$	$2·30 \times 10^{-6}$		$2·30 \times 10^{-4}$
1,4-Naphthaquinone	$4·59 \times 10^{-6}$	$2·30 \times 10^{-5}$	$4·59 \times 10^{-5}$	$4·59 \times 10^{-5}$
1,4-Anthraquinone	$4·59 \times 10^{-6}$	$4·59 \times 10^{-6}$	$2·30 \times 10^{-5}$	$2·30 \times 10^{-5}$

benzophenone, benzil and quinones an apparent intercept for zero gap setting. This intercept was practically constant, at a value of about 2 kV, and independent of the nature of the additive and its concentration.

I thank Prof. M. W. Humphrey Davies for providing the facilities to carry out this work and Dr. H. Tropper for his advice.

CHEMISTRY

Physical Transitions of the Alkali Metal Nitrates as Revealed by Differential Thermal Analysis

Differential thermal analysis experiments have been carried out on the alkali metal nitrates, lithium nitrate, sodium nitrate, potassium nitrate, rubidium nitrate and cæsium nitrate. These experiments were conducted in air at the nominal heating rate of 10° C/min. Differential thermal analysis curves of the alkali metal nitrates were previously reported[1]; however, the use of smaller sample masses, bare thermocouples and the different thermocouple location and arrangement used in the present work considerably improved the resolution of the differential thermal analysis curves. This was also found to be true in the case of potassium perchlorate[2]. The results of the nitrate experiments are shown in Figs. 1, 2, 3, 4 and 5. Generally, the essential features of the curves for lithium, sodium and cæsium nitrates are in agreement with previous work[1]. In the case of potassium nitrate a slight exothermal rise was reported to occur immediately prior to fusion[1]. This is not observed in our work as may be seen in Fig. 3.

The marked increase in the resolution of the differential thermal analysis peaks was revealed to be especially important in the case of rubidium nitrate. This resulted in the observation of a previously unreported endotherm at 302° C. The differential thermal analysis curve for rubidium nitrate shows good resolution of all the endotherms. Five endotherms are clearly revealed. The first three due to crystalline transitions and the fifth due to fusion have been reported[1], although they did not appear as discrete individual bands as recorded here. The fourth endotherm, which involves a very small heat change, estimated from Fig. 4 to be 50 cal/mole, may easily be obscured in a poorly resolved curve, and consequently was not previously observed. The maxima of the five differential thermal analysis bands, which represent the transition temperatures and melting point, for rubidium nitrate occur at 167°, 236°, 290°, 302° and 314° C. The corresponding peaks occur at 172°, 241°, 293°, 303° and 315° C. Thermogravimetric analysis shows that decomposition does not occur during these endotherms, consequently the fourth endotherm at 302° is almost certainly due to a crystalline transition, previously unknown for

rubidium nitrate. Replicate experiments confirm these results. Plyushchev, Markina and Shklovev identified the first three crystalline transitions from phase transformation diagrams at 164°, 219° and 291° C (ref. 3) and reported the melting point at 314° C (ref. 4). These values are in fair agreement with the results of the present work with the exception that the temperature of the second transition is 17° lower than our value of 236° and also the crystalline transition at 302° was not reported.

The differential thermal analysis apparatus used has already been described[2]. Briefly, it consists of a metal block for the reference and sample containers, and 'Pyrex' test-tubes which are heated simultaneously at a pre-

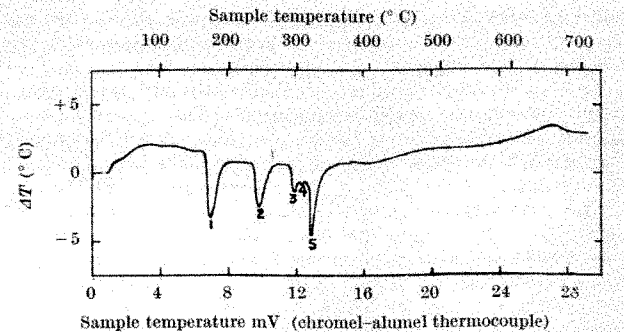

Fig. 4. Differential thermal analysis, $RbNO_3$, 500 mg, in air. Heating rate, 10° C/min

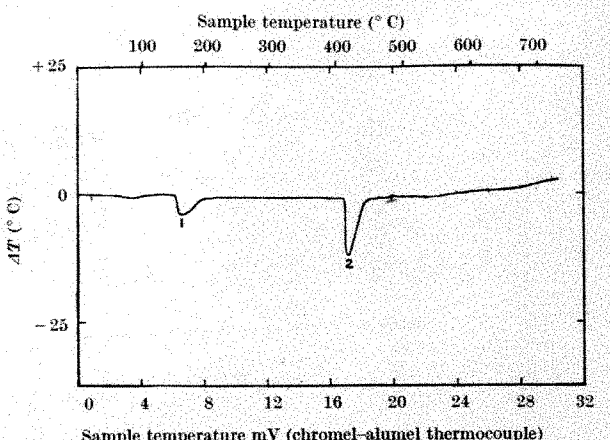

Fig. 5. Differential thermal analysis, $CsNO_3$, 500 mg, in air. Heating rate, 10° C/min

determined heating rate, in this case 10° C/min. The rate of heating was regulated by a West Gardsman controller. Temperature differences between the sample and thermally inert reference compound, calcined alumina, were plotted as a function of sample temperature on a Mosely *X*—*Y* autograph recorder. 500 mg samples were run at atmospheric pressure in air. The 28-gauge chromel–alumel thermocouple wires were spread apart and shaped to fit along the bottom of the sample container. All the samples with the exception of rubidium nitrate were twice recrystallized from triply distilled water. The rubidium nitrate was four times recrystallized. All the starting materials were of C.P. grade.

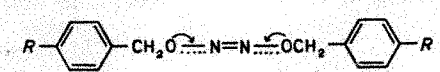
Effect of Alkyl and Halo Substituents on the Homolytic Dissociation of Dibenzyl Hyponitrites

Polar effects showing consistent trends with the nature of substituents and satisfactory correlations with the Hammett equations have been observed in the homolytic dissociations of benzoyl[1] and thenoyl peroxides[2], *t*-butyl perbenzoates[3], phenylperacetates[4] and peroxycarbamates[5], and *m*-substituted phenylazotriphenylmethanes[6]. In all these reactions electron-repelling substituents have been found to increase reaction rate whereas electron-with-



drawing substituents lower rates, the magnitude of the effects being much smaller than in ionic reactions.

A consistent trend with substitution, but in the reverse sense to that already noted, is now reported for the first-order homolytic dissociation of some symmetrically substituted dibenzyl hyponitrites. The final products of decomposition, the respective benzaldehydes, benzyl alcohols and nitrogen, are similar to those reported for the parent dibenzyl hyponitrite[7], where the activation energy for the first-order decomposition, about 25 kcal, obtained manometrically at maximum inhibition has been confirmed by radical counting methods using iodine and diphenylpicrylhydrazyl[8]. Table 1 lists rates for the first-order decomposition of 0·05 M solutions of the substituted compounds in nitrobenzene obtained manometrically in the presence of *p*-benzoquinone (0·8 M) in excess of that required for maximum inhibition.

Table 1. First Order Constants for the Decomposition, at 35·4°, of Substituted Dibenzyl Hyponitrites (0·05 M) in Nitrobenzene in Presence of 0·8 M *p*-Benzoquinone

Substituent	*m*-CH_3	*p*-CH_3	H	*p*-Cl	*p*-Br	*m*-Cl
$10^5\,k$ (sec^{-1})	6·22	6·31	6·50	6·80	6·93	7·11

An extreme variation of 15 per cent in the value of the rate constant is observed in changing from the *m*-CH_3 to the *m*-Cl substituent, the electron-attracting halo substituents increasing the rate whereas the weakly electron-releasing methyl groups decrease the rate, relative to the unsubstituted compound. The effects of substitution may be understood from the nature of electronic influences in dibenzyl hyponitrite, where the known electron-withdrawing tendency of the azo-group[9,10] should lead to an increase in the N—O bond order as depicted in the formula:

This tendency is strongly marked in the hyponitrite anion where infra-red studies of the N—O stretching frequency by Le Fevre *et al.*[11] and by Kuhn and Lippincott[12] indicate an N—O bond order greater than one. Relative to the unsubstituted compound, the effect of electron-repelling and electron-attracting substituents would be, respectively, to increase and decrease the N—O bond order. The relative order of the rates is therefore consistent with a mechanism involving the simultaneous rupture of the two N—O bonds[7] with the formation of the stable nitrogen molecule. A similar mechanism has been invoked in other radical reactions involving the elimination of nitrogen[13]. A Hammett plot (Fig. 1) is satisfactory with the exception of the *p*-methyl substituent. The small value of the reaction constant as compared with other radical dissociations is expected from the damping of pure inductive effects and the absence of any direct resonance interaction with the locus of reaction.

A wider range of substituents is being examined.

This work was initiated at the University of Hong Kong. I thank Prof. J. E. Driver for his interest.

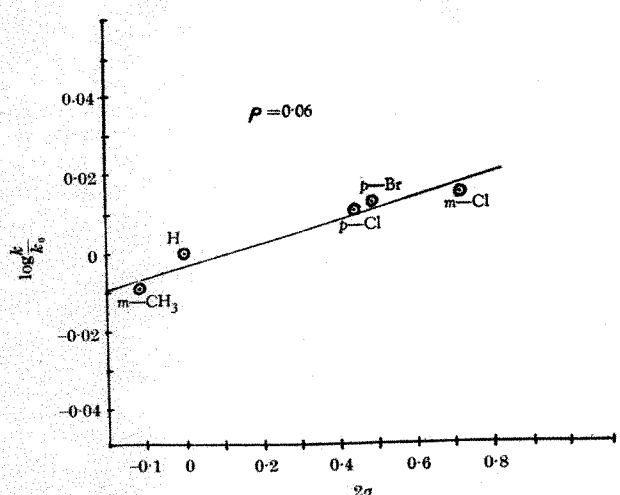

Fig. 1

The Partition Law in Solvent Extraction

The thermodynamic law for the partition of a solute between two immiscible or partially miscible solvents is:

$$a = Ka'$$

where a and a' are the activities in the two phases, and K is a constant. This law is frequently used to determine a' when a is known[1]; but we are unaware of any instance in which independent determinations of a and a' have been compared with measured partition data.

We have now carried out such an investigation of the system HCl–H_2O–TBP (tri-*n*-butyl phosphate) at 25° C. Activities of hydrochloric acid in water are of course well known, partition data have been obtained by various authors[2], and we have determined activities of hydro-

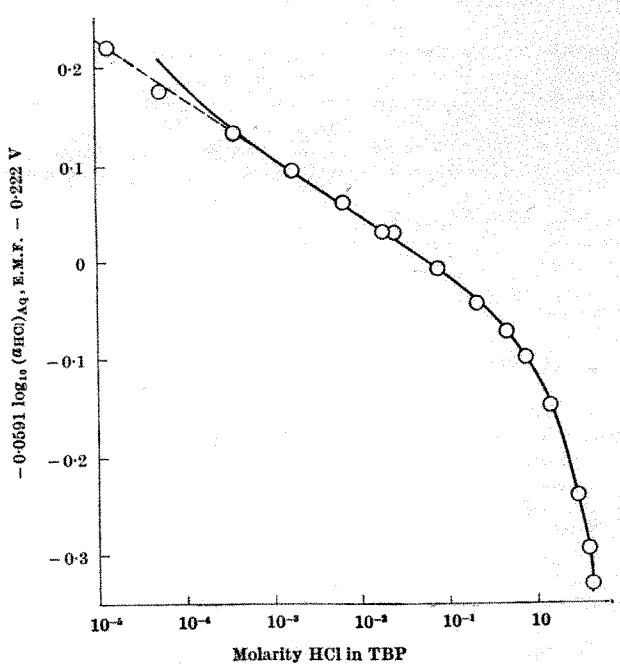

Fig. 1. Comparison of electrochemical and distribution data for activity of hydrochloric acid in tri-*n*-butyl phosphate

chloric acid in the TBP phase by E.M.F. measurements on the cell:

$$H_2,Pt|HCl(m) \text{ in TBP}|AgCl,Ag$$

We have shown that the hydrogen and silver/silver chloride electrodes are reversible in TBP.

For the corresponding aqueous solution cell, the E.M.F. is given by:

$$E = E_0 - 0{\cdot}05914 \log a_{HCl}$$

For the TBP solution cell just mentioned it is given by:

$$E' = E_0' - 0{\cdot}05914 \log a'_{HCl}$$

If the solutions in the two cells are in partition equilibrium, then from the first law of thermodynamics, $E = E'$. Hence:

$$E' - E_0 = -0{\cdot}05914 \log a_{HCl}$$

The accepted value of E_0 is 0·222 V (ref. 3).

Fig. 1 shows $E' - E_0$ (circles) and $-0{\cdot}05914 \log_{10} a_{HCl}$ (solid line based on Hesford and McKay's results[2], which cover the required concentration range), plotted against the concentration of hydrochloric acid in the TBP phase. The agreement is good except at very low concentrations where the measurements become difficult.

Pertechnic Acid : an Aperiodic Variation in Acid Strength

For a given oxidation level the oxy-acids in a given sub-group of the periodic table are normally found to exhibit a regular variation in acid strengths. In group VII, for example, Cobble[1] lists the logical pK values as $-2{\cdot}25$, $(-1{\cdot}5)$ and $-1{\cdot}25$ for $HMnO_4$, $HTcO_4$ (estimated, with due regard for the lanthanide contraction) and $HReO_4$. The general behaviour of pertechnic acid in aqueous neutralimetry certainly is consistent with that of a monoprotic and 'relatively' strong acid.

On the other hand, Kertes and Beck[2] conclude a paper on the tributyl phosphate extraction of Tc(VII) with the dilemma: "Consequently, the origin of the different extractabilities of $HTcO_4$ and $HReO_4$ found, lies in their different acid strengths and it follows that $HReO_4$ is a stronger acid than $HTcO_4$. The respective position of the elements in the Periodic Table definitely suggests the opposite. This discrepancy shows that, although the acid strength is an important factor governing the extractability of acid by oxygen containing extractants, it is probably not the only one. Consequently, some other factors not yet known seem to be more determining".

The sometime red colour of $HTcO_4$, the unexplored possibility of mesopertechnetates, the (H^+)-dependence of certain liquid-liquid extractions of Tc(VII) (refs. 3 and 4), the nature of Re/Tc separations on anion-exchange resins, the polarographic and the spectrophotometric behaviour of pertechnetate ion versus pH (refs. 3 and 4)—all have been examined or are now being examined in this laboratory. Each of these phenomena has an obviously requisite, or a more subtly probable, dependence on the ionization constant of pertechnic acid.

The acid ionization constant itself is now being measured precisely and as a function of temperature. From our earlier results[4], K_{ion} of $HTcO_4$* at 25·4° C is about $5 \pm 2 \times 10^{-1}$. This value of 0·5 is nearly one-hundred-fold less than the anticipated value of 32, and is well below the K_{ion} of 18 for $HReO_4$. We also find that this low value is requisite for a logical explanation of the ether extraction of pertechnetate from aqueous media of various pH (ref. 4).

Of course, this surprisingly aperiodic behaviour may possibly be explained in terms of dimerization, hydration, or similar, factors. Present research is directed toward seeking this explanation, and the expression $HTcO_4$* may represent an over-simplification respecting the measured acidity. Our acid was prepared by the dissolution in distilled water of Tc_2O_7, made by the combustion in oxygen of Tc[99] obtained in 99·9 per cent purity from the Oak Ridge National Laboratory.

Trace Analysis by Combined Chromatographic Techniques

The application of gas chromatography to the determination of trace impurities may be considerably extended by using a combination of chromatographic techniques. We may illustrate this by the following example in which concentrations of alkenes in alkanes as low as 1 in 10^8 have been readily and precisely determined.

n-Heptane was first freed from alkenes by passing the liquid through a column of alumina modified with silver nitrate (about 10 g of packing per 100 g of heptane). In the first series of experiments, quantities of 1-hexene and 1-heptene ranging from 1 to 10 mg each were added to 100 g of the purified heptane. The resulting samples were then forced under slight nitrogen pressure and at room temperature through a similar modified alumina column (3 mm internal diameter and 1 g packing). When the column was free of liquid its temperature was raised to 75° C and nitrogen passed through to elute the last traces of heptane. The hexene and heptene were then displaced from the column by a stream of nitrogen saturated with 1-octene. The resulting chromatogram (gas-density detector) is shown in Fig. 1, the dotted lines representing the hexene and heptene steps. The lengths of these steps were found to be proportional to the quantities of alkenes introduced into the heptane, so that this method may be used directly for concentrations down to 1 in 10^5.

In the second series of experiments 1 μg quantities of 1-hexene, 1-heptene and 2-heptene were added to 100 g of purified heptane. Such samples were treated as in the first

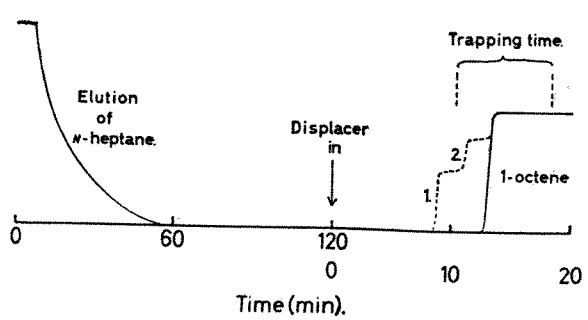

Fig. 1. Elution of last traces of n-heptane and displacement of alkenes (step 1 = hexene, step 2 = heptene) from a column of alumina modified with silver nitrate

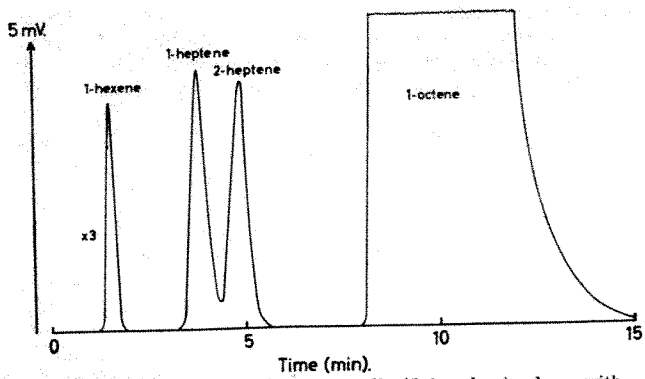

Fig. 2. Analysis of octene-front on gas-liquid (squalane) column with flame-ionization detector. 1 μg each of 1-hexene, 1-heptene (b.p. 94·9°), and 2-heptene (b.p. 98·1°) from 100 g *n*-heptane (b.p. 98·5°)

series to produce the chromatogram shown in Fig. 1 but without distinct hexene and heptene steps. The front of the octene step was trapped out over the period shown and analysed with a gas-liquid elution chromatograph to give the chromatogram shown in Fig. 2. The same peak areas were obtained when either 1 or 2 g of packing was used in the displacement column, indicating that there was no significant irreversible adsorption.

In a preliminary series of experiments, 100 g samples of unadulterated pure heptane were treated as in the second series of experiments. The final gas-liquid elution chromatograms contained no discernible peaks before the emergence of the octene.

For the second series of experiments and for the 'blanks', the octene displacer was itself prepared by a pseudo-displacement technique in which 25 g of the modified alumina was first saturated with commercial octene at room temperature. This was then purged with nitrogen, and the column temperature finally raised to 120° C to release about 1·5 g of purified octene, which was trapped out at low temperature.

There would appear to be no inherent difficulty in extending the method to much lower concentrations, and to other types of trace impurities by appropriate choice of selective column material. The displacement method lends itself to preparative work, thus quantities of an alkene of the order of 2–5 g (depending on molecular weight) could be extracted pure from alkanes with a 100 g silver nitrate modified column. The purification procedures outlined here for heptane and octene should also have application in the preparation of solvents suitable for the extraction of trace materials. We propose to illustrate these further developments in future publications.

Polymerization of a Thermosetting Polymer in an Electric Field

There has recently been a considerable amount of discussion and speculation[1] as to the possible effects on a polymer from polymerization in a relatively strong electric field. The possibility of using this technique to yield polymers which would have unusual physical and/or electrical properties has been considered. Presented in this communication are the results obtained during an investigation of the polymerization of a thermosetting polymer in constant electric fields of various strengths.

The monomer consisted of 30 per cent styrene and 70 per cent of a linear condensation polymer of maleic and phthalic acids with propylene glycol. The source of free radicals was 1 per cent methyl ethyl ketone peroxide. Polymerization was conducted at 80° ± 2° C at field strengths varying from 125 to 25,000 V/cm in small concentric cylindrical electrodes[2]. High voltage was supplied by a DuMont type 263-*B* power supply which was connected directly to the electrodes.

In the initial experiments the conductivity of the polymer was followed continuously during polymerization by a continuous current monitoring device[3] in a manner very similar to that previously described[2,4]. However, at higher field strengths (> 2,500 V/cm) the electric field produced unusual changes and accelerations in the rates of polymerization. Since these changes were not reproducible, attempts to monitor the conductivity during these polymerizations were not continued. Similar effects have been noted recently by Khaletskii and Sukhorukov[5].

We have found[4,6,7] that the dependence on temperature of the electrical volume resistivity is a sensitive index of the extent of polymerization and is indicative of structural changes in the polymer[8]. For comparative purposes the activation energy for the electrical conduction process E_c, which is calculated from the temperature dependence of the resistivity, is a more convenient parameter. Therefore, immediately after polymerization in the electrical field the temperature dependence of the resistivity was determined. This determination was made at a low (~ 200 V/cm) field strength.

The results of this work are shown in Fig. 1 where the E_c values obtained after isothermally polymerizing a series of samples at 80° ± 2° C in electric fields of various strengths for four hours are plotted against the electric field strength. It will be noted that E_c decreases as the field strength is increased. For example, $E_c = 46$ kcal/mole for a polymer polymerized at ~ 200 V/cm while E_c decreases to 32 kcal/mole for a sample polymerized at 25,000 V/cm (5,000 applied volts). Since smaller E_c values indicate less temperature dependence of the resistivity we see that with increasing field strength during polymerization the temperature dependence of the resistivity decreases. Thus, the effect of polymerizing in an electric field is to produce a polymer which is somewhat more conductive in a direction parallel to that of the applied

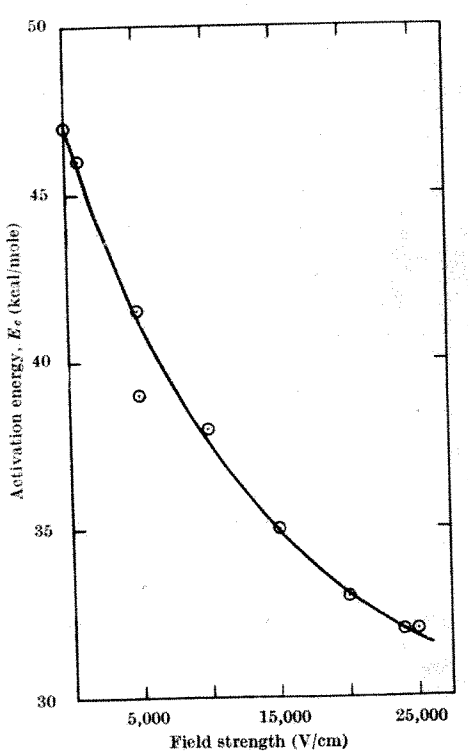

Fig. 1. Dependence of activation energy for electrical conduction in the solid polymer on the field strength during polymerization

field. This effect is more pronounced at higher field strengths.

This effect is relatively small and probably results from minor structural changes. This is evidenced by the fact that the magnitude of the resistivity exhibited only a slight decrease and that the glass transition temperature, T_g, of a polymer polymerized at a field strength of 16,000 V/cm is ~ 123° C as compared with a T_g of 126° C for the same material polymerized in the absence of an applied field.

We conclude that the application of relatively high electrical fields during polymerization produces some degree of alignment or orientation of the polymer structure and that one of the effects of this form of ordering is to reduce the temperature dependence of the resistivity.

We thank Mr. T. J. Wade for assistance in the experimental phase of this investigation.

Isomerization of 1,2-dichloroethylene induced by Chlorodifluoromethyl Radicals : Formation of Metastable Radicals

It has been reported that radicals produced by the decomposition of benzoyl peroxide in the liquid phase cause the rapid isomerization of *cis* and *trans* 1,2-dichloroethylene in the liquid phase in the temperature-range 80°–135° C (refs. 1 and 2). It is supposed that the isomerization is brought about by chlorine atoms which react with the olefines to form 1,2,2-trichloroethyl radicals which rapidly decompose to give the original 1,2-dichloroethylene or its isomer. This reaction has recently been shown to intervene in the chlorination of 1,2-dichloroethylene, even at lower temperatures[3]. The chlorine atoms in the first-mentioned isomerization process are supposed to be formed by displacement from the olefine by a free radical derived from benzoyl peroxide. No direct evidence has previously been obtained for such a process.

In the present investigation the products of the reaction of chlorodifluoromethyl radicals, produced by the photolysis of 1,3-dichlorotetrafluoroacetone[4] with the isomers of 1,2-dichloroethylene, were examined using gas chromatography. The major reaction brought about was the isomerization of the olefine. In addition to unreacted ketone, and the isomers of the olefine, the reaction products were found to contain 1,2-dichlorotetrafluoroethane and an additional major component. No dichlorodifluoromethane was detected, although this compound is known to be formed in small amounts by the abstraction of a chlorine atom from 1,3-dichlorotetrafluoroacetone by chlorodifluoromethyl radicals[5]. The additional component was isolated from a number of gas chromatography runs in sufficient amount to allow its identification by mass spectrometry as 1,3-dichloro-3,3-difluoropropene.

The absence of dichlorodifluoromethane and of 1,2,3-tetrachloro-1,1-difluoropropane shows that the named propene could not have been formed in disproportionation reactions. Although gas chromatography revealed a minor product having a retention time close to that expected for the appropriate substituted propane, this component was present in too small an amount either to permit its identification or to account for the formation of much of the substituted propene. We must suppose, therefore, that the observed propene is formed by the decomposition of 1,2,3-trichloro-3,3-difluoropropyl radicals. No data are available to enable the estimation of the energy required for the dissociation of the propyl radical to give the olefine, but energies for such processes are commonly about 20 kcal/mole (for thermally equilibrated radicals). The rapid decomposition of the radicals in this case at temperatures in the range 25°–60° C can be understood only if the decomposing species are excited. Dainton[3] has recently shown that the 1,2,2-trichloroethyl radicals formed by the addition of a chlorine atom to 1,2-dichloroethylene are formed in an excited state which may easily decompose with a small or zero energy of activation by loss of a chlorine atom. Dainton supposes that the decomposition involves nascent radicals containing the energy with which they are formed. The decomposition of the substituted propyl radical examined in the work recorded here is not the reverse of that leading to its formation, and the decomposition must follow at least a redistribution of energy within the radical. It may be significant that the carbon–chlorine bond in the propyl radical is likely to be weaker than the carbon–carbon bond that would be broken in the reaction that is the reverse of that by which the radical is formed.

This work has provided evidence of the formation of a radical in a relatively long-lived metastable state, and has confirmed a mechanism postulated for the isomerization of the isomeric 1,2-dichloroethylenes by free radicals. Whether all the observed isomerization proceeds through the chain reaction involving chlorine atoms, as has been proposed by previous workers, or whether some results from the breakdown of the substituted propyl radicals to regenerate chlorodifluoromethyl radicals, will be difficult to decide. Further investigation of these phenomena is intended.

One of us (H. D.) thanks the Department of Scientific and Industrial Research for a maintenance grant. We thank Dr. J. R. Majer for mass spectrometric results.

BIOCHEMISTRY

A Possible Mechanism of Synthesis of Nucleic Acids

In the organism, *B. megaterium*, it is possible to separate from the cytoplasm a nuclear fraction which contains all the DNA of the cell, some protein and about 3 per cent of the cellular RNA[1]. It has been found that the DNA polymerase is present both in the nuclear fraction and in the cytoplasm, but the whole of the RNA polymerase is present in the nuclear fraction[2].

These enzymes are not easily removed from the nuclear fraction by mild procedures; in particular it has been found that in order to liberate the RNA polymerase it is necessary to disrupt the DNA with DNase[2] and it is necessary to conclude that this enzyme is firmly bound to DNA in the complex. In the case of mammalian nuclei, it has also been found[3] that certain enzymes are active when present in the nucleus in complexes; for example, in regenerating liver, thymidylate kinase cannot be detected in *in vitro* assays until an hour or two after the onset of DNA synthesis although it must have been

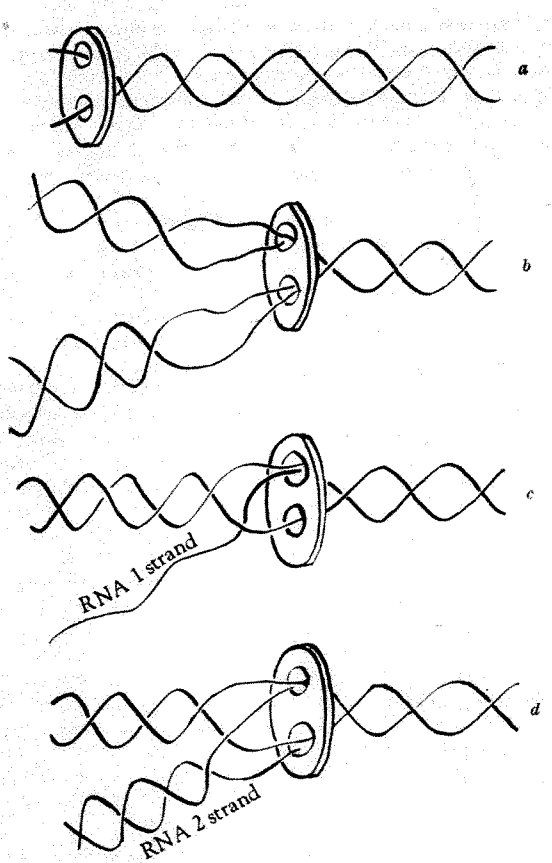

Fig. 1. Schemes of synthesis of DNA and RNA

present previously to produce the necessary DNA precursors. On the basis of this evidence it has been suggested by Bianchi *et al.*[3] that such enzymes only appear in the cytoplasm when the stage of the cell-cycle at which they are active in the nucleus is finished.

The facts suggest a highly organized arrangement of the enzymes concerned with the nuclear synthesis of DNA and RNA. The following mechanism is suggested as a possible mode of association of the DNA and RNA polymerase which require DNA as a primer. The enzyme is envisaged as a kind of disk (Fig. 1) with two holes or slots each of which can accommodate one of the strands of the primer DNA. The disk will first attach itself to one end of the DNA fibre with the end of one strand in each hole, as in (*a*). The complementary nucleotide for the given position in the sequence will now take its place, and as these are attached one by one to the growing chain the disk will move forward along the DNA fibre, rotating as it goes and thereby unwinding the double-stranded helix. This avoids the difficulties which have been suggested[4] of finding a mechanism for unwinding the helix. The energy required to separate the strands will come from the synthetic reaction involving the precursor triphosphates. The new double strands emerging can be expected to wind up in a helix, the energy required being provided by the short-ranged attractive forces between the bases. The new fibres would also be loosely wound around each other; a feature which is often seen in photographs of chromosomes. In this scheme the enzyme molecule is located at branching points, where the division of the fibres occurs. It may be observed that electron micrographs of DNA have often been obtained which show such branching and that a thickened blob is sometimes seen at the branching point which may well be due to an enzyme molecule.

Evidence has been given by Kornberg that the two strands of the DNA fibre are of opposite polarity[5]. This means that looking down the fibre in one direction, one strand has the phosphates attached to deoxyribose in the 3 and 5 positions in the order *p*, 5, 3, *p*, 5, 3, etc., while in the other strand the reverse is the case, that is, *p*, 3, 5, *p*, 3, 5, etc. On the proposed mechanism the enzyme must be capable of bringing about the polymerization of strands having both polarities simultaneously. This will, of course, be necessary in any mechanism in which the replication of a DNA fibre occurs, starting at one end. That replication in the DNA occurs sequentially has been shown by Cairns[6] with *E. coli* DNA, who observed 'forks' similar to those predicated here.

A similar mechanism with the appropriate enzyme may be presumed to operate in the case of synthesis of RNA on a DNA template. In this case two possibilities exist: (1) a complementary thread of RNA is attached at one of the holes only, as in Fig. 1*c*, giving a single-stranded RNA, while the DNA fibre coils up again behind the disk; (2) a double-stranded RNA could be formed as in Fig. 1*d*. Insufficient is known at present about nuclear RNA to distinguish between these possibilities.

There has been some uncertainty whether the DNA polymerase in fact makes use of (*a*) single-stranded (or denatured DNA) or (*b*) double-stranded. Bollum[7] prepared a calf thymus polymerase which used (*a*) but not (*b*). On the other hand, the enzyme of Lehman *et al.*[8] from *B. coli* undoubtedly uses both. In the mechanism proposed, anomalies of this kind might easily occur. Some special configuration, for example protein, may be required at the end of the fibre to enable the enzymes to become attached and in its absence it may be easier for the enzyme to cope with single-stranded than double-stranded DNA.

Note added in proof. At the recent Cold Spring Harbor symposium on "Nucleic Acid Replication", Cairns showed pictures of the circular chromosome of *E. coli* in the course of replication in which the new and old strands of DNA are certainly not coiled around each other, and to account for this suggested that the original strand was capable of rotation. If this applied to the model shown here, that is, if the original strand of DNA to the right of the disk is allowed to rotate, the necessity of coiling of the new and the old fibres around each other will be avoided.

Carbamylation of Oxytocin and Arginine-Vasopressin

Synthetic analogues of oxytocin and vasopressin in which the terminal amino group is absent or modified exhibit remarkable differences in biological activity. Whereas desamino-oxytocin is highly active[1,2], analogues of oxytocin in which the amino group is substituted by acylation or alkylation retain little pharmacological activity[3–5], and some act as antagonists[4,6]. Similarly, 1-desamino-8-lysine-vasopressin has a relatively high

pressor potency[1] while 1-*N*-acetyl-8-lysine-vasopressin is inactive[7].

A recent report[8] that cyanate reacts with the terminal amino groups of proteins and peptides under mild conditions to form carbamylated derivatives has suggested to us the possibility of preparing 1-*N*-carbamyl analogues of oxytocin and vasopressin. Such analogues would be of particular interest since the carbamyl group differs chemically from both acyl and alkyl substituents. In order to determine optimal experimental conditions for the preparation of *N*-carbamyl analogues, we have treated oxytocin and vasopressin with cyanate and studied the effect on pharmacological activity.

The procedure used was to allow synthetic oxytocin or arginine-vasopressin to react with potassium cyanate at 30° C; the solutions were maintained at *p*H 5·0 or 6·0 by automatic addition of 2·5 M acetic acid. When the reaction was allowed to proceed for 120 min at *p*H 5, additional cyanate was added after 60 min to restore the initial concentration, the reagent having a half-life of 32 min under these conditions. At intervals, aliquots of the reaction mixture were removed and the reaction was stopped by acidification with concentrated hydrochloric acid to *p*H 2, which destroys cyanate. Residual activity in neutralized samples was determined by bioassay. Oxytocic activity was assayed on the isolated rat uterus, milk-ejecting activity on the lactating guinea pig, pressor activity on the blood pressure of the rat, and antidiuretic activity in the water-loaded rat under ethyl alcohol anæsthesia[9]. In control experiments, a solution containing 0·04 M cyanate was acidified to *p*H 2; oxytocin or vasopressin was added after 30 sec and the reaction mixture incubated for 2 h. Full recovery of activity was obtained with both hormones.

On treatment with 0·2 M potassium cyanate at *p*H 6, oxytocin (1 U./ml.) was rapidly inactivated. The residual oxytocic activity was 6 per cent at 10 min, and 1·5 per cent at 30 min. In order to obtain more information about the rate of inactivation and to provide greater protection for the disulphide bond, the concentration of cyanate was reduced to 0·04 M and the *p*H adjusted to 5. Under these conditions a slower rate was observed; but after 120 min, as shown in Table 1, both oxytocin and vasopressin were almost completely inactivated. No significant dissociation of biological activities could be detected since the rates of inactivation measured on different assay systems were similar. During the assays there was no inhibition of the responses to threshold doses of standard oxytocin or vasopressin.

To establish the specificity of the cyanate reaction, desamino-oxytocin (0·2 μg/ml.) was treated with 0·04 M cyanate for 120 min under the same conditions. No inactivation was observed; the recovery of oxytocic activity was 102 per cent and that of milk-ejecting activity 96 per cent. This strongly suggests that the inactivation of oxytocin and, by inference, vasopressin, is the result of a specific reaction of cyanate with the terminal amino group.

The finding that oxytocin and vasopressin are rapidly inactivated by 0·04 M cyanate directs attention to the irreversible inactivation of oxytocin by urea[10]. Since a concentration of 0·02 M cyanate is present at equilibrium in 8 M urea[11], this inactivation could be attributed to a chemical reaction with cyanate rather than to a physical effect involving a change in molecular conformation. Our results emphasize the necessity for caution in the use of urea in biochemical investigations[12].

Table 1. Residual Activity (%) in Samples of Oxytocin (2 U./ml.) and Arginine-vasopressin (1 U./ml.) treated with 0·04 M Potassium Cyanate at *p*H 5 and 30° C

Reaction time (min)	Oxytocin		Arginine-vasopressin	
	Oxytocic activity	Milk-ejecting activity	Pressor activity	Antidiuretic activity
5	51	69	—	—
6	—	—	51	—
10	31	50	44	—
30	10	15	11	—
60	3	3	2	2
120*	0·1	0·07	< 0·2	0·04

*The values for oxytocin at 120 min were obtained with an initial concentration of 50 U./ml.

Experiments are now in progress to isolate the *N*-carbamyl derivatives of oxytocin and vasopressin for detailed chemical and pharmacological examination. The reaction of cyanate with angiotensin and bradykinin is also under investigation.

The preparation of *N*-carbamyl analogues of biologically active peptides may prove useful both in elucidating the functional importance of their terminal amino groups and in producing potential antagonists.

We thank Prof. V. du Vigneaud for a gift of desamino-oxytocin, and Dr. H. Holgate of Sandoz Products for gifts of oxytocin and 8-arginine-vasopressin.

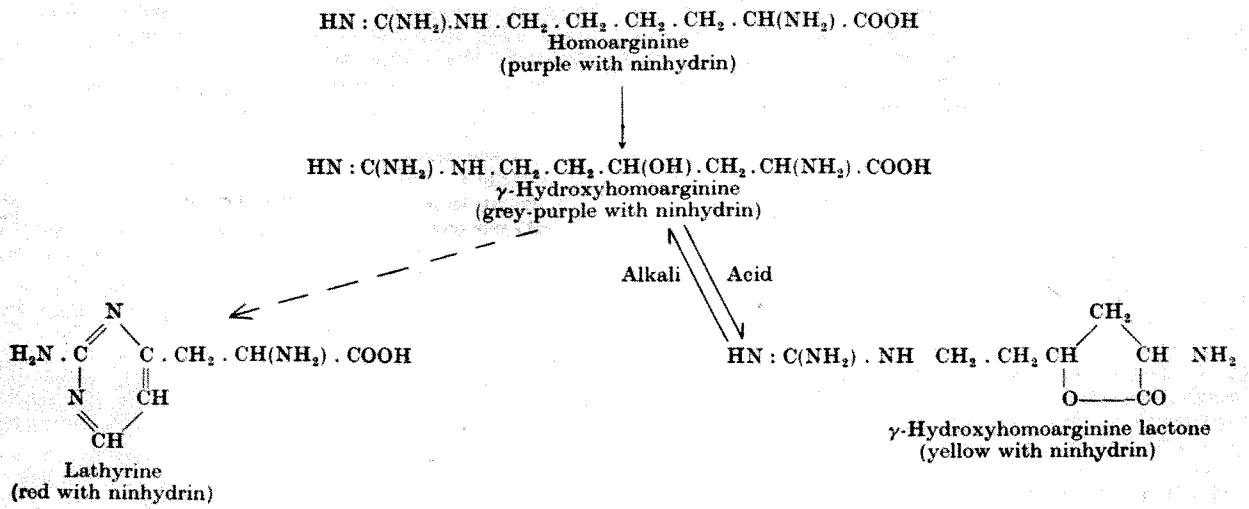
A New Amino-acid, γ-Hydroxyhomoarginine, in *Lathyrus*



A study of free amino-acids and related compounds in *Lathyrus* revealed the presence of lathyrine[1] and two other ninhydrin-reacting compounds of unknown constitution, designated B_1 and B_3, in the seeds of *L. tingitanus* and three other species, *L. aphaca*, *L. cyanus* and *L. sphaericus*[2].

The identities of lathyrine and B_1 were afterwards established as 2-aminopyrimidin-4-ylalanine[3] and L-homoarginine[4] respectively. It is now reported that B_3 has been isolated from seeds of *L. tingitanus* and shown to be α-amino-γ-hydroxy-ε-guanidinocaproic acid (γ-hydroxyhomoarginine).

After removing lathyrine from finely ground seed of *L. tingitanus* with methanol, the guanidino amino-acids (homoarginine and B_3) were extracted with 50 per cent aqueous ethanol, the extract concentrated and passed successively through columns of 'De-Acidite *FF*' and 'Zeo-Karb 226'. The basic amino-acids were eluted from the cation exchange resin with ammonium hydroxide and the unknown (B_3) freed from homoarginine by the repeated recrystallization of its flavianate. The purified flavianate was decomposed with concentrated hydrochloric acid, excess acid removed with aniline and the hydrochloride recrystallized from hot ethanol.

As in the isolation of γ-hydroxyarginine from *Vicia sativa*[5] this procedure induced a transformation, and a more basic guanidino compound giving a yellow reaction with ninhydrin was isolated. This artefact (which reverted to the original compound in alkaline solution) analysed as the dihydrochloride of a hydroxyhomoarginine lactone or isomer, m.p. 214°. Found: C, 32·71; H, 6·41; Cl, 27·47; N, 21·95. $C_7H_{16}O_2N_4Cl_2$ requires C, 32·44; H, 6·18; Cl, 27·41; N, 21·62 per cent.

The free hydroxy acid behaved as an α-amino-monocarboxylic acid when treated successively with cupric nitrate and ninhydrin[6], while the failure of the original compound or the product of its alkaline hydrolysis (the corresponding diamino-acid) to yield ammonia when

treated with periodate indicated that the hydroxyl group was vicinal neither to the α-amino-group nor to the guanidino group.

Lactone formation ruled out the possibility of the hydroxyl group being in the ε position and the possible structures resolved themselves to α-amino-β-guanidino-δ-hydroxycaproic acid or α-amino-γ-hydroxy-ε-guanidinocaproic acid (γ-hydroxyhomoarginine). On lactonization these compounds would form δ- and γ-lactones respectively. The infra-red spectrum of the isolated lactone showed a strong peak at a frequency of 1,762 cm^{-1}, which was absent from the spectrum of the hydroxy acid itself. This characteristic absorption confirmed the presence of a γ-lactone and the identity of the original compound as γ-hydroxyhomoarginine.

Comparisons made between the spectra (infra-red and nuclear magnetic resonance) of the isolated lactone and those of γ-hydroxyarginine lactone were consistent with this conclusion.

Using L-homoarginine labelled with carbon-14 it has been shown this amino-acid is the precursor of γ-hydroxyhomoarginine in *L. tingitanus*, and it would seem probable that hydroxylation is the first step in the postulated[4] conversion of homoarginine to lathyrine in the plant.

I thank Prof. H. Harris for his interest, Mr. G. E. Hirst for determining the infra-red spectra and Mr. R. G. Foster for determining the nuclear magnetic resonance spectra.

Pigment Formation by *Penicillium rubrum* Stoll

During an investigation on the appearance of red-pigmented patches on chrome-tanned hide it is found that this pigmentation is caused by the growth of *Penicillium rubrum* Stoll on it. Though such pigmentation is a common phenomenon, its occurrence is not frequent. *Penicillium rubrum* Stoll, like other members of *Penicillium purpurogenum* series, represents almost a common mycoflora of soil and other organic matter and produces red pigmentation on the substrate on which it grows. Therefore, the rarity of occurrence of such pigmentation on chrome-tanned hide and, in fact, on other organic matters is surprising and obviously suggests some strict specificity involved in pigment formation by *Penicillium rubrum* Stoll. Some of these specificities have been determined on laboratory culture media. Sabouraud's medium with 1·0 per cent 'Bactopeptone' (Difco), 4·0 per cent glucose A.R. (B.D.H.), 2·5 per cent agar, *p*H 5·0–5·5, is taken as the basal medium on which *Penicillium rubrum* Stoll produces intense red pigmentation in 4–8 days at 23°–25°. Substitution of one or the other constituent of the medium was made for specific studies. Abbreviations used for visual assessment of the formation of pigment are *P*− =pigment nil; *P*+ = pigment positive; each additional plus (+) sign indicates proportional increase in intensity of the pigment.

Ability of a number of different nitrogenous materials, and amino-acids when individually used as the sole source of nitrogen and of various 'sugars' and carbohydrates to produce pigment in Sabouraud's medium, have been determined. The extent of pigmentation observed after 8 days is given in parentheses.

Nitrogenous materials (1·0 per cent w/v): 'Bactopeptone' Difco (*P*++++); 'Proteose peptone' Difco (*P*++++); 'Peptone Italian' (*P*++++); 'vitamin-free casamino-acid' Difco (*P*++++); 'Bacto gelatin' Difco (*P*+); 'Bacto yeast extract' Difco (*P*+).

Amino-acids (1·0 per cent w/v; L-isomers are used unless otherwise stated): glycine (*P*−); glutamic acid (*P*+); aspartic acid (*P*−); leucine (*P*−); phenyl alanine (*P* trace); *dl*-tryptophan (*P*−); β-alanine (*P*++); arginine hydrochloride (*P* trace); asparagine (*P*−); glutamine (*P*−); histidine hydrochloride (*P*+++); proline (*P*−); hydroxyproline (*P*−); lysine hydrochloride (*P*−); cystein hydrochloride (*P*++++); *dl*-valine (*P*+); tyrosine (*P*−); *dl*-methionine (*P*−); glutathione (−SH) (*P*++++).

Sugars, etc. (4·0 per cent w/v): glucose (*P*++++); sucrose (*P*++++); maltose (*P*++++); lactose (*P*−); mannitol (*P*++): glycerine (*P*++); starch (*P*++).

Absence either of the source of nitrogen or of sugars or other carbohydrates in the medium invariably failed to show any pigmentation even though in some cases fair to

Table 1. Effect of Different Concentrations (% w/v) of Peptone and Glucose in the Basal Medium on Pigment Production by *P. rubrum* Stoll

Period (days)	'Bactopeptone' variable; glucose 4·0								'Bactopeptone' 1·0; glucose variable					
	(4·0)	(3·0)	(2·0)	(1·0)	(0·5)	(0·2)	(0·1)	(0·05)	(4·0)	(3·0)	(2·0)	(1·0)	(0·5)	(0·1)
4	*P*−	*P*−	*P*++++	*P*++++	*P*++++	*P*++++	*P*+++	*P*+++	*P*++++	*P*++++	*P*++	*P*−	*P*−	*P*−
8	*P*−	*P*−	*P*++++	*P*++++	*P*++++	*P*++++	*P*+++	*P*+++	*P*++++	*P*++++	*P*++	*P*−	*P*−	*P*−

good growth of the mould was obtained. This shows that growth and pigmentation do not always go side by side.

The question whether for a positive pigmentation 'peptone' and 'sugar' are required to be present in any definite concentration or mere presence of them, irrespective of the amount, will do the job, has been investigated and the results obtained are given in Table 1.

It is significant that while the pigmentation is fairly good when the peptone is as low as 0·05 per cent, it is nil when glucose is brought down to the level of 1·0 per cent. In all probability, it suggests that provided nitrogen is present in the medium to initiate the mycelial growth pigmentation will occur if glucose is above a certain level. It further suggests, in view of fairly high requirement of glucose for a positive reaction, that glucose, either by itself or through some intermediates, is linked chemically in pigment formation. The specificity shown by the mould for its cultural requirement of amino-acids as a source of nitrogen appears to be fairly rigid even though the pigment (phoenicine[2]) has been shown to be of a composition ($C_{14}H_{10}O_6$) containing no nitrogen[3]. Detailed work will be published elsewhere.

I thank Dr. Y. Nayudamma, director of the Central Leather Research Institute, for his interest in this work and the director of the Commonwealth Mycological Institute, Kew, England, for identifying the strain of *Penicillium*.

Astringency of Persimmons (*Diospyros kaki*, L.)

It is a well-known fact that unripe persimmons which are fully coloured but firm are astringent, and that on ripening the astringency disappears concomitant with a softening of the fruit into a jelly-like consistency.

It has also been long known that interruption of respiration by placing the firm fruit in an atmosphere of alcohol will render the fruit non-astringent without accelerating the softening process. Traditionally, it was the practice to store the fruit in casks previously used to store sake, and the residual alcohol was sufficient to process the fruit in four or five days. This practice was examined as early as 1912 by Gore[1], and it was found that carbon dioxide as well as other gases could be used[2]. The action of sulphur fumes in preserving the astringent taste normally destroyed in drying was noted by Cruess and Joslyn in 1929 (ref. 3).

The cause of the astringency has been ascribed to tannins, and one of the mechanisms proposed for the removal of astringency involves the combination of soluble tannin with soluble pectin[4].

More recently, it has been shown by Bate-Smith[5] and Swain[6,7] that a large number of food tannins include leucoanthocyanins, also called anthocyanogens, or more recently, flavolans. These are flavanoid compounds which yield anthocyanidins on heating with mineral acid. They occur as monomers and polymers, usually in conjunction with catechins.

The tannin of persimmons appears to fall into this category. It has recently been shown that the major constituent of the tannin includes leucodelphinidin-3-glucoside[8]. The unusual nature of this tannin is that it is one of the few examples of an anthocyanogen which is a glycoside. All the observed properties of its solubility behaviour are in accord with the proposed structure.

This communication records the effects of certain processing conditions on the tannin content.

An initial experiment with the Hachiya variety was run in 1961 and concerned the changes occurring in the phenolic compounds during the ripening of persimmons under natural storage conditions. A summary of the results is shown in Table 1 (ref. 12).

Table 1

Date of sampling	Total phenolic (ref. 9) compounds (mg/g fruit)	Catechin type (ref. 10) compounds (mg/g fruit)	Anthocyanogens (ref. 11) (O.D./5 ml. extract)
Nov. 16	13	0·60	0·98
Nov. 23	7·5	0·20	0·42

The 1962 work was concerned with the correlation of the astringent factor with the leuco compounds. Preliminary work using segments of fruit showed that the juice of the astringent fruit would colour red on the application of vanillin and hydrochloric acid to a far greater degree than that of the ripe fruit. Staining of the fruit itself reveals that the amount in the juice represents only a small fraction of the total. Nevertheless, it is concluded that the soluble fraction would be more important in the astringency which is definitely different.

Firm orange fruit of the Hachiya variety were selected and divided into lots of five fruits as uniform as possible. One lot was kept at 0° C while the others were placed in large jars and exposed to alcohol vapour (11 ml./gal.), nitrogen alone and air. Another lot was coated with paraffin at approximately 50° C and cooled instantly. These were then stored for 5 days at room temperature (22° C). The fruit flesh was then subjected to shear press measurements. A second experiment using younger fruit showed that the alcohol action could be applied to firm fruits where the texture did not appreciably alter. The pulp was then recovered and tasted. The results are shown in Table 2.

Table 2. Shear Press Measurements, Relative Resistance to Shear

	Exp. 1		Exp. 2	
Initial	100	extremely astringent		
Control	32	astringent	59	astringent
Over-ripe	29	non-astringent		
Alcohol-treated	32	non-astringent	83	non-astringent
Wax-coated	47	slightly astringent		
Nitrogen	94	extremely astringent		

The results calculated as cyanidin, although the actual pigment appears to be delphinidin, are shown in Table 3.

Table 3. Anthocyanogen Content of the Methanol Extract (p.p.m.)

Initial	1,800	Alcohol-treated	8
Control	965	Wax-coated	58
Over-ripe	15	Nitrogen	1,050

The absorption curve of the developed colour showed a single maximum at 555 mμ and correlates with that found by Ito and Oshima[8].

Firm astringent and non-astringent fruit were blended in a Waring blender to give a smooth paste. 'Pectinol' (Rohm and Haas) was then added to each. Within 30 min, the non-astringent one showed signs of hydrolysis with attendant liquification of the pulp. After standing 12 h, the difference was striking. The astringent one still preserved its paste-like consistency while the non-astringent one was liquefied and had a distinct aroma reminiscent of the flavour of dried persimmons. The ability of the astringent pulp to tan enzymes is apparent here.

Astringent fruit at 0° C was peeled and placed in a humid oven at 40° C. Core samples were obtained at hourly intervals from 5 mm inside the surface. The results are shown in Fig. 1, and it is seen that a sharp decrease occurs between 2 and 6 h.

A quantity of non-astringent persimmons was obtained from the University Farm and the extract was compared with the astringent variety. The methanol extract contained no soluble leucoanthocyanins except for a small amount next to the skin. The distribution of soluble leucoanthocyanin through the fruit is shown in Fig. 2.

The pulps were then placed in hydrochloric acid–methyl alcohol, brought to boiling, and allowed to remain

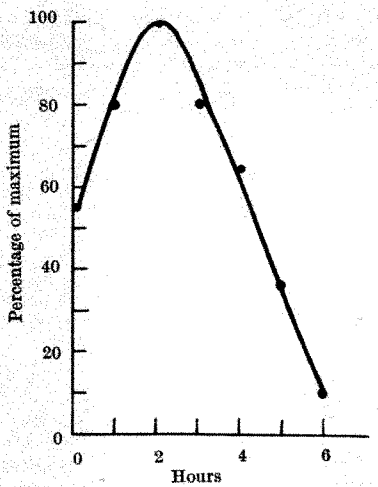

Fig. 1. Changes in soluble anthocyanogens of peeled fruit at 40° C

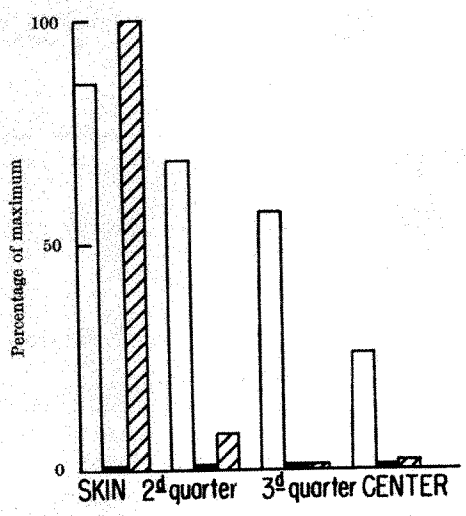

Fig. 2. Distribution of anthocyanogens in the fruit. White, astringent variety; black, astringent variety treated with alcohol; hatched, non-astringent variety

overnight. They were then extracted and the filtrate concentrated and chromatographed on Whatman No. 1 filter paper with BuOH : HOAc : HOH (4 : 1 : 5 v/v). The R_F value for the main violet-coloured spot was 0·40–0·42 on the astringent, non-astringent and combined extracts. A small spot was present at 0·62 in all samples. A large brown area remained at the origin and formed a curtain. The violet spots were eluted and the maximum in hydrochloric acid–methyl alcohol was 545 mμ. From these results it is concluded that the anthocyanidin was delphinidin, confirming the work of Oshima, and that a delphinidin generating leuco compounds is also present in the non-astringent variety.

It is concluded that a soluble form of a delphinidin-generating colourless compound is responsible for the astringent taste of unripe persimmons. These compounds can be either transformed or destroyed by interruption of the respiration. It also appears that in view of the fact that a great deal of these compounds remain in non-astringent fruit, there are astringent and non-astringent forms. The naturally non-astringent types appear to be a result of the absence of the soluble form.

The presence of the tannin appears to have some protective value as birds appear to attack only those fruits which are non-astringent. Among three trees located together—non-astringent, astringent but fully ripe, and an astringent only firm ripe—the birds had devastated the first two. This is reminiscent of the case of sorghum in which bird-proof sorghum is unpalatable due to its high content of anthocyanogens.

We thank Dr. Roy Young of the Department of Subtropical Horticulture, University of California, Los Angeles, for a discussion on post-harvest physiology.

Hydroxylation of Phenoxyacetic Acid by Stem Tissue of *Avena sativa*

Recent work in this Department[1,2] has demonstrated that phenoxyacetic acid is rapidly converted into a number of products by the stem tissues of several plant species. Further research has now established that, under certain conditions, mesocotyl segments of *Avena sativa* within 24 h can convert phenoxyacetic acid almost completely into four main products.

These processes were followed by allowing the segments to take up phenoxy-[1-^{14}C]-acetic acid, followed by extraction of the tissue and a separation of the radioactive compounds by paper chromatography. A typical record of such a chromatogram is shown in Fig. 1, where it will be noted that the greatest amount of radioactivity is contained within the peak labelled *Z*. Under the experimental conditions used, 70 per cent of the total radioactivity extracted from the tissue was applied to the chromatogram, and of this about 40 per cent was found as substance *Z*.

In order to identify this compound the following procedures were adopted. Segments were cut from the mesocotyls of *Avena* seedlings raised in the dark at 25° C for five days. These segments were then placed in buffered aqueous solution containing the potassium salt of phenoxy-[1-^{14}C]-acetic acid at 8×10^{-4} M and incubated for 24 h in the light. The segments, after rinsing, were extracted with hot ethanol, and the extract was concentrated and applied to a polyamide[3] ('Perlonpulver') column. Fraction *Z* was adsorbed to an appreciable extent, and after washing the column with water, the compound could be eluted with methanol. Further purification of *Z* was effected by paper chromatography using as solvents

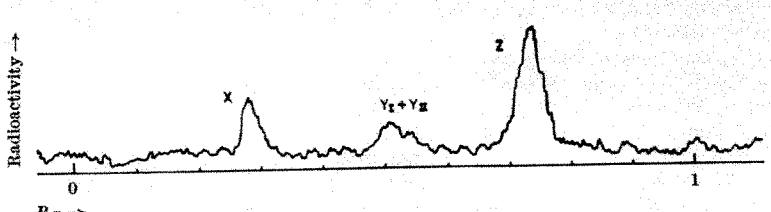

Fig. 1. Distribution of radioactivity in a chromatogram of *Avena* tissue extract on Whatman No. 3 *MM* paper developed in butanol/propionic acid/water (2 : 1 : 1·3). Phenoxyacetic acid has an R_F of 0·89

butanol/propionic acid/water (2 : 1 : 1·3) and isopropanol/ammonia (*d*, 0·88)/water (20 : 1 : 2). Finally the product was crystallized from a mixture of benzene and petroleum ether b.p. 60°–80° C. In this way 10 mg of white crystals m.p. 152°–153° C were obtained from 250 g of *Avena* tissue.

This product was stable to acid and alkaline hydrolyses and showed selective absorption in the ultra-violet region —λ_{max} 285 mμ *p*H 2 and λ_{max} 305 mμ *p*H 11. Phenoxyacetic acid itself has λ_{max} 267 mμ independent of *p*H. These facts and the adsorption of *Z* on to the polyamide suggested a phenolic structure for *Z*[3–5].

In 1957 it was reported by Byrde and Woodcock[6] that phenoxyacetic acid was converted to 2-hydroxy- and 4-hydroxy-phenoxyacetic acids by *Aspergillus niger*. Dr. Woodcock kindly supplied authentic samples of these compounds. Compound *Z* was found to be identical to 4-hydroxy-phenoxyacetic acid in the following respects. (1) λ_{max} 285 mμ *p*H 2, λ_{max} 305 mμ *p*H 11; (2) m.p. 152°–153° C (authentic sample 152°–154° C); (3) R_F 0·42 in isopropanol/ammonia/water (20 : 1 : 2); (4) R_F 0·75 in butanol/propionic acid/water (2 : 1 : 1·3); (5) The same purple colour was developed with diazotized sulphanilic acid.

The foregoing results are considered to be sufficient to distinguish between 4-hydroxy- and 2-hydroxy-phenoxyacetic acids[6].

Little is known of the enzymatic mechanisms involved in such reactions. Klämbt[7] has recently shown that benzoic acid is hydroxylated by *Helianthus annuus*, while Harborne and Corner[8] have described hydroxylation of cinnamic acids in a variety of plants. The existence of this system, which may well be a mechanism for the detoxification of phenoxyacetic acid, suggests that enzymes capable of introducing hydroxyl groups into aromatic rings may be widely distributed in the plant kingdom. The characteristics of the enzyme involved in this particular case are now being investigated.

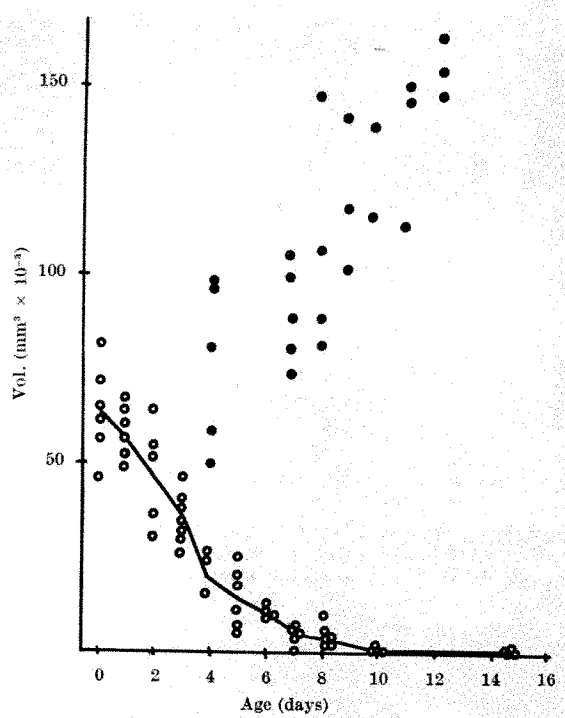
PHYSIOLOGY

Effect of Cortisone on Extra-adrenal Chromaffin Tissue of the Rat

It has been assumed that the differentiation of primary sympathetic cells into chromaffin cells is stimulated by hormones produced by the adrenal cortex[1]. These hormones have also been thought to be necessary in the methylation of noradrenaline into adrenaline[2]. However, while medullary catecholamines are known to cause an increased secretion of cortical hormones[3], no direct evidence is available of the influence of cortical hormones on chromaffin cells.

In the course of an examination of the chromaffin tissue of the rat, I observed that administration of cortisone strongly affects the normally rapid post-natal disappearance of chromaffin cells from the extra-adrenal chromaffin tissue. Fig. 1 illustrates the age-dependent changes in the volume of this tissue, measured planimetrically from serial sections, in normal and cortisone-treated rats. In the normal rat, the disappearance of extra-adrenal chromaffin cells occurs very rapidly. After the first post-natal week there are a few faintly chromaffin cells left only in the main para-aortic body, frequently called the organ of Zuckerkandl. Administration of cortisone, if started during the first two post-natal days, prevents the disappearance of the chromaffin cells from this organ and brings about the appearance of numerous new strongly chromaffin cells in it, in smaller abdominal para-aortic bodies and in structures such as the sympathetic ganglia, in which normally none or only a few weakly chromaffin cells are seen. The planimetrically measured volume of the extra-adrenal chromaffin tissue therefore increases. Moreover, the intensity of the chromaffin reaction clearly increases during cortisone treatment, while it gradually weakens in untreated rats (Fig. 2).



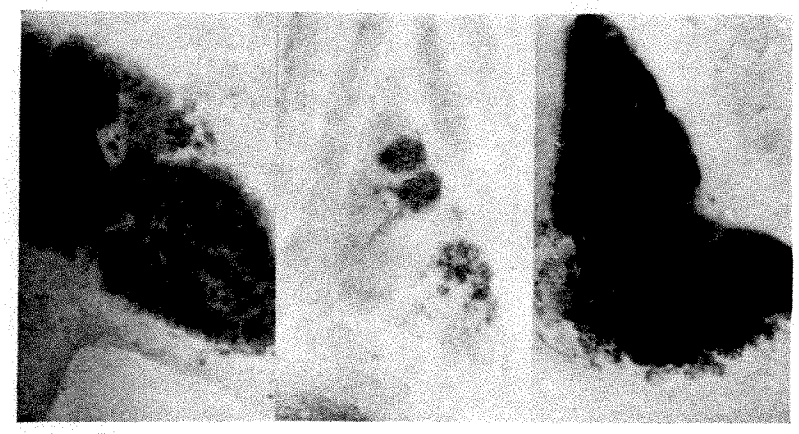


Fig. 1. Effect of age and cortisone on the volume of the extra-adrenal chromaffin tissue of the rat. Open circles, untreated controls; full circles, rats injected daily with 0·25 mg of cortisone after birth

The effect of cortisone depends on the administration being made sufficiently early. Cortisone does not cause regeneration of the cells once they have lost their 'chromaffinity' and started to degenerate. The appearance of new chromaffin cells in the sympathetic ganglia also seems to depend on their developmental stage: the less primary, undifferentiated sympathetic cells present when the cortisone administration is initiated, the less new chromaffin cells appear.

Hydrocortisone exerts an influence similar to that of cortisone described here. Adrenocorticotrophic hormone is capable of preventing the disappearance of chromaffin cells from para-aortic bodies, but does not cause an increase in the volume of extra-adrenal chromaffin tissue. Deoxycorticosterone is without any effect on the chromaffin cells.

No effects of cortical hormones on intra-adrenal chromaffin tissue were observed, which is not surprising, since most of the cells in the adrenal medulla are clearly chromaffin already three days after birth, and the intensity of the chromaffin reaction in them increases with age even in untreated rats.

So far as I know, these observations are new and provide the first direct evidence of the influence of cortical hor-

A B C

mones on chromaffin cells. Comprehensive interpretation of these observations will not be attempted in this brief report. However, they suggest that enclosure inside the adrenal cortical tissue, which provides a flow of cortical hormones, may be a condition for subsequent normal development and secretory function of chromaffin medullary cells.

This work is part of a research project on the function of the adrenal medulla directed by Prof. Olavi Eränkö and supported by research grant No. *A*–1725 from the National Institute of Arthritis and Metabolic Diseases, U.S. Public Health Service.

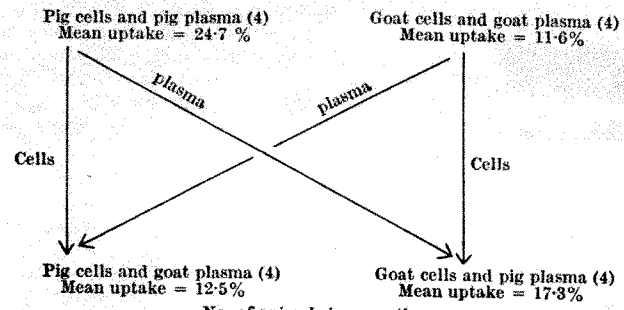
Uptake of Iodothyronines by Erythrocytes *in vitro* in Various Species

It has been shown that the electrophoretic mobility of thyroxine labelled with iodine-131 in human serum corresponds with the inter-α zone globulins, thyroxine-binding protein (TBG). The capacity of the serum TBG for thyroxine is limited but the physiological 'saturation' of its binding sites varies with the state of thyroid activity. It is relatively saturated with endogenous thyroxine in the hyperthyroid and relatively unsaturated in the hypothyroid state[1]. Thus the binding of thyroxine added to serum varies inversely with the thyroid function. If the competition between red cells and the binding sites of TBG is expressed in terms of *in vitro* 'uptake' of radioactive tri-iodothyronine ('Trix') by red cells, the uptake is higher in thyrotoxic and lower in myxœdematous persons[2], and the binding coefficient of red blood cell uptake of 'Trix' is negatively correlated with the TBG capacity.

So far, only investigations of human serum have been described in detail, and very little is known about serum TBG capacity in animals. The presence of TBG in animals has been shown, but the precise pattern in the α-globulins differs between species[1]. This is also true with reference to the presence or absence of the thyroxine-binding pre-albumin substance of serum. No TBG has been found in chicken and duck sera[3]. It may be anticipated, therefore, that variation in the properties of the thyroxine-binding proteins in animals may be given in turn a species difference in the uptake of labelled iodothyronines *in vitro* by erythrocytes. In fact 5·4 and 2·5 per cent uptakes of labelled thyroxine by red cells of rabbit and sheep respectively have been observed previously[4]. This communication represents further data on the differences between uptakes in various animals.

The experiment involved animals of 6 species, kept under normal farm conditions. Blood samples were drawn from the jugular vein, or from the brachial wing vein in the case of hens, directly into a heparinized syringe. Thyroxine-131 and tri-iodothyronine-^{131}I ('Trix') in 50 per cent aqueous propylene glycol were obtained from the Radiochemical Centre, Amersham, England. Their purity, not less than 90 per cent, was checked by ascending chromatography, on Whatman No. 3 filter paper, in two solvent systems, *n*-butanol – dioxan – 2 N ammonia and *n*-butanol – glacial acetic acid – water. Under standardized conditions, whole blood was incubated for 2½ h at 37° C with the labelled iodothyronines in a corked flask on a rotating plate. Thyroxine-^{131}I or 'Trix' was added in quantities of 15·6–57·6 × 10^{-4} μg in 0·1 ml. isotonic saline per 1 ml. of whole blood. At the end of the period of incubation the radioactivity of 1 ml. of whole blood was estimated in a well-type scintillation counter. After 5 washes with 0·9 per cent saline the radioactivity remaining in the red cell mass was determined in the same centrifuge tube as before, with a counting accuracy of ± 2 per cent. From the proportion of counts of red blood cells to count in whole blood, the percentage of uptake was calculated. For comparative purposes the uptake was corrected to 100 per cent hæmatocrit. The results are shown in Table 1.



The uptake of 'Trix' varies between species; it is three times greater in hen and rabbit than in the ruminants with values for the pig occupying a middle position. On the other hand, uptake of thyroxine-^{131}I is nearly the same in the ruminant group and pig, but greater in hen and rabbit. The higher uptake of thyroxine-^{131}I in rabbit in comparison with other mammals confirms a previously noted observation[4]. A positive correlation between 'Trix' and

Man	Adult (euthyroid)	13·3[3]	± 1·9					11–29·0[1]	5·3[8]

No. of animals in parentheses.

Table 2

No. of animals in parentheses.

uptake of thyroxine-^{131}I has been observed in individual hens ($r = 0{\cdot}9$; $P < 0{\cdot}01$).

For comparative purposes Table 1 includes published figures for serum TBG capacity and protein-bound iodine-level. There is clearly no relationship between levels of uptake of protein-bound iodine and 'Trix'. The same cannot be said about the relationship between TBG and uptake because of inadequate information. With reference to the hen, however, high uptake of both iodothyronines seems to correspond to an observed lack of TBG in chicken and their different response to tri-iodothyronine and thyroxine in comparison with mammals[3]. It is possible that the high uptake of 'Trix' and thyroxine-^{131}I in rabbit is partly connected with the fact that in normal conditions rabbit serum is relatively saturated with endogenous hormones[5].

Table 2 shows a criss-cross experiment on the inter-species recombination of red cells and plasma. In this experiment, unwashed red cells were mixed with plasma of different species. After 2 h of incubation, although a slight tendency to agglutination and hæmolysis was observed, the addition of goat plasma to pig red cells decreased uptake of 'Trix' from 24·7 to 12·5 per cent and the addition of pig plasma to goat red cells increased uptake from 11·6 to 17·3 per cent. This shows that goat thyroxine-binding proteins have a greater affinity for 'Trix' than those of pig plasma, and is in general agreement with present views on the competition for 'Trix' between binding sites on the red cells and those on the proteins in the serum.

Effect of Melanocyte-stimulating Hormone on the Eye of the Rabbit

The aqueous flare is a scattering phenomenon, which may be observed when a beam of light passes the anterior chamber of the eye. It is caused by the presence of substances with large molecules (proteins). Using a photographic apparatus[1] for measuring the intensity of the flare, Anjou, Krakau and Stigmar[2] observed that an injection of chromatographically pure preparations of ACTH may cause an increase, sometimes quite impressive, of the flare density in normal eyes of rabbits. The maximum density occurred about 3 h after the injection; then the flare intensity faded slowly. The flare effect was regularly accompanied by a reduction of the intraocular pressure. No effect could be seen after vasopressin.

The investigation has been continued with a photoelectric modification of the previous device[3]. Suspecting that the effect might be elicited via the adrenals a series of adrenal hormones (cortisone, hydrocortisone, deoxycorticosterone and norepinephrine) were tested. No responses as a consequence of these were observed.

With α- and β-melanocyte-stimulating hormone (supplied by A. V. Schally and R. Guillemin, Baylor University, Houston, Texas), however, the typical effect on the flare was obtained with a dosage of about 3 μg/kg (s.c.). The effect on the flare density is due to an increased permeability of the blood-aqueous barrier. This was demonstrated by means of intravenously injected fluorescein, which passes into the anterior chamber in far greater amounts during the period of increasing flare than is normally the case.

The idea that we are dealing with an influence on the melanocytes of the eye is in agreement with the fact that ACTH shows a melanocyte-stimulating hormone effect. It also agrees with anatomical facts—thus the pigment epithelium is found in the boundary layer between the small vessels and the non-pigmented epithelium in the ciliary processes. Finally, strong support is provided by the observation that the effect can be provoked mainly in pigmented rabbits, whereas there is practically no response in albinotic animals to the doses administered (one slight reaction observed in a series of 10 albino rabbits).

The present finding may possibly have some bearing on certain previous observations on diurnal variations provocable by light in the physiological flare intensity, and on other phenomena connected with aqueous dynamics.

Selective Stimulation of Intra-cardiac Postganglionic Fibres

It was observed by Lewis *et al.*[1] that the duration of the refractory period of the electrically stimulated auricles may be increased by atropine. They believed that the effect may be ascribed to the stimulation of the intra-auricular parasympathetic fibres by the driving stimuli. Since that report, the effects of the stimulation of the intra-cardiac parasympathetic and/or sympathetic nerve fibres superimposed on the effect of stimulation of the heart muscle or sino-auricular node have been observed by other authors[2–4]. Brady *et al.*[5] described the inotropic effect of series of impulses applied during the refractory period of the cardiac muscle.

In this communication a simple method of selective stimulation of the intra-auricular postganglionic fibres is described.

The auricles of the young rabbits anæsthetized with chloralose (0·1 g/kg intravenously) were isolated with both vagus nerves attached, following McEwen's method[6]. They were mounted in a bath of Tyrode solution containing 250 mg sodium bicarbonate/l. and saturated with 100

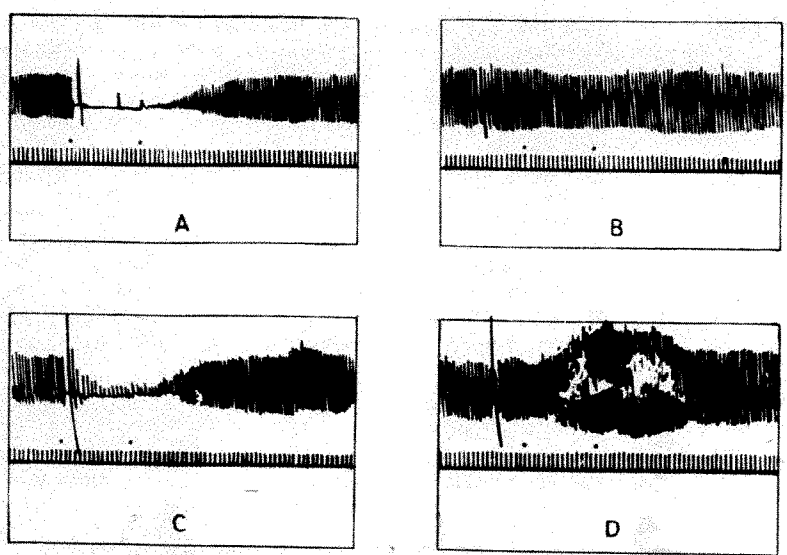

Fig. 1. From above downward: contractions of the isolated rabbit auricles, the dots indicating the nerves stimulation, time at 1-sec intervals. *A*, Response to the stimulation of both vagus nerves; *B*, stimulation of both vagus nerves after hexamethonium (2×10^{-4} g/ml.) has been added to the bath; *C*, response to the direct stimulation of the intra-cardiac postganglionic fibres; *D*, response to the direct postganglionic stimulation after atropine (1×10^{-5} g/ml.) has been added to the bath

per cent oxygen at a temperature of 35° C. Both nerves were left freely in the bath. They were placed on the electrodes for the time of stimulation only. The contractions of the auricles were recorded by means of the light lever writing on a smoked drum.

A pair of the round-plate silver–silver chloride electrodes, connected to the Grass stimulator (model *S4D*), was placed in the bath, to stimulate the intra-cardiac nerve elements. The diameter of the positive electrode was 10 mm. It was placed about 10 mm. from the auricular surface to face the orifice of the inferior vena cava. The diameter of the free surface of the negative electrode was 2 mm. It was placed about 2 mm from the auricular surface to face the area lying at the angle between the orifice of the vena cava superior and the base of the right appendix. The purpose of the placing of the electrodes was to submit the parasympathetic fibres and ganglia, situated in the sino-auricular node region, into the influence of the electric field generated in the bath by the tetanizing rectangular stimuli.

Both vagus nerves were stimulated for 30 sec in each 5 min with supramaximal rectangular stimuli of 10 msec duration at the rate of 30/sec. Stimulation was started 30 min after the auricles had been isolated. When the stable and reproducible responses had been obtained (Fig. 1*A*), hexamethonium was added to the bath to obtain a final concentration of 2×10^{-4} g/ml. This was sufficient to block the transmission in the intra-auricular parasympathetic ganglia, as was shown by McEwen[6] (Fig. 1*B*). After complete blockage had been effected, the rectangular stimuli of a duration of 0·01 msec–0·25 msec at a rate of 100/sec were applied by means of the plate electrodes. It was possible to obtain pure negative chronotropic and inotropic responses followed by the positive effects after the stimulation had been stopped. No extra systoles were observed, provided the strength of the stimuli was properly adjusted (Fig. 1*C*).

The negative responses were reversed by atropine in a concentration of 1×10^{-5} g/ml. (Fig. 1*D*). No responses to the direct stimulation by means of plate electrodes could be obtained after hemicholinium No. 3 (ref. 7) had been added to the bath at a concentration of 1×10^{-5} g/ml. and the vagus nerves stimulated up to complete disappearance of responses. These results suggest that the negative effects were due to the stimulation of the intra-auricular parasympathetic postganglionics and not to the stimulation of the auricular muscle or the sino-auricular node. Release of acetylcholine was the important link in the positive effects, since these disappeared under the influence of hemicholinium.

The optimal conditions for the selective stimulation of intra-auricular postganglionic fibres were tested. The threshold strength of the stimuli evoking the easily noticeable negative response was tested and the strength–duration curve recorded. Another strength–duration curve was recorded for the threshold stimuli evoking the auricular extrasystoles, and both curves compared. As may be seen in Fig. 2, the difference between the threshold values for nerve elements and those for auricular muscle is greatest with very short stimuli and disappears completely when the duration of the stimuli exceeds 0·20 msec.

The simple and easy method of selective stimulation of intra-auricular parasympathetic fibres is provided by these experiments. This method may be useful, if knowledge of the site of action (preganglionic endings or postganglionic endings) of some vagolytic drug is required.

Urine-concentrating Mechanism in Man

Although many extensive investigations in animals[1–3] have demonstrated the existence of renal medullary hyperosmolality suggestive of a counter-current mechanism of urine concentration, direct evidence of medullary hyperosmolality in man has never been obtained hitherto. We have examined the tissue concentrations of sodium, potassium, urea and ammonia in human kidneys removed at operation or shortly after death, using standard techniques[4].

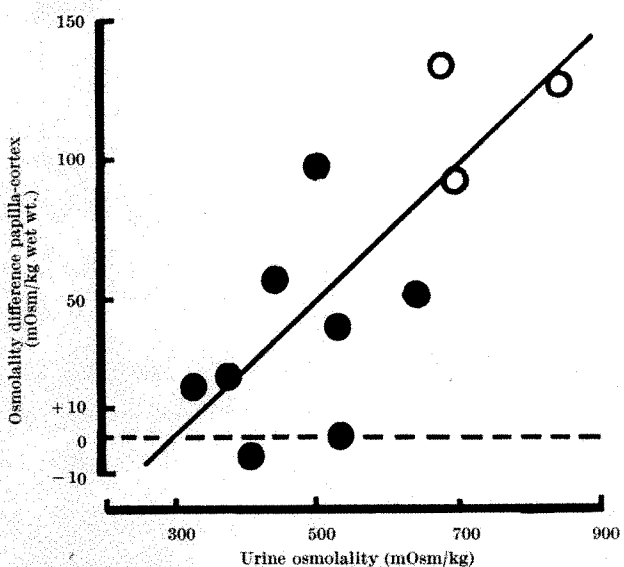

Fig. 1. Relationship of cortico-papillary tissue osmolality gradient to urine osmolality. ○, Nephrectomy specimens; ●, post-mortem specimens. Calculated regression line formula is $y = 0{\cdot}228\,x - 66{\cdot}8$; $r = 0{\cdot}76$; $0{\cdot}01 > P > 0{\cdot}001$

The results in Table 1 show that there is a rise in sodium and urea tissue concentrations from cortex to papilla in persons producing hypertonic urine; potassium and ammonia concentrations show little change. A more detailed report, including an investigation of renal solute concentration changes after death, will appear elsewhere[5]. The relationship between urinary osmolality and the cortico-papillary tissue osmolality gradient is highly significant, $r = 0{\cdot}76$; $0{\cdot}01 > P > 0{\cdot}001$, the calculated regression line formula being $y = 0{\cdot}228x - 66{\cdot}8$. The regression line reaches urinary isotonicity with plasma at a tissue osmolality gradient of zero; this differs from the findings in dogs in which there is a persistent cortico-papillary tissue osmolality gradient even in extreme water diuresis[6], but we have not had the opportunity of examining human kidney tissue under conditions of urinary hypotonicity.

The importance of sodium and urea in producing an increase in tissue osmolality in the human papilla is similar to that found in dogs[2] although the absolute values are lower; this correlates well with man's inferior maximal urinary concentrating ability when compared with the dog.

The increasing cortico-papillary tissue osmolality gradient with increasing urine concentration supports the hypothesis that urine concentration in man is carried out by a counter-current mechanism.

Micro-injection of Trypsin into Axons of Squid

Recent work appears to show that phospholipids play a fundamental part in membrane physiology[1,2]. The participation of protein has been thought by some to be more doubtful since external application of proteases seems not to interfere with electrical function of squid, lobster or frog axons[3–5]. However, it should be recalled that externally applied protease does produce injury potentials in muscle[4]. Attempts to demonstrate that protease had entered squid axons without producing changes in electrophysiological properties may have been in error even though the controls at the time seemed appropriate[3].

This communication presents, without further interpretation, the results of five experiments which indicate that nerve proteins do play an important part in impulse generation.

Pieces of giant axons (1,000–1,500μ in diameter and 5 cm long) from the large squid *Homastrephes gigas* were used in these experiments. A micropipette (100–200μ tip diameter) was introduced longitudinally into the axon from one end. This pipette was connected to a syringe filled with mineral oil to which pressure could be applied. The pipette was also connected by means of a T tube and an agar sea-water bridge to a calomel electrode. Another calomel electrode was in contact through an agar sea-water bridge with the external medium (natural sea-water). In this way, the micropipette was used both to inject solutions into the axon and to measure resting and action potentials. Stimulation was effected with two external platinum-electrodes.

Resting potentials were within the range of 40–45 mV. Overshoots were between 20 and 35 mV. After measuring resting and action potentials, approximately 10^{-3} c.c. of

a trypsin solution (1 mg/c.c. at *p*H 7·3) was injected along the axon as the pipette was slowly withdrawn, the solvent being a salt solution mimicking the cytoplasmatic ionic composition. During the first minute after injection, the fibre was excitable at 60/sec and threshold was not modified. At the beginning of the second minute threshold increased, and by the end of the second minute only local responses were elicited. After five minutes the local response too had disappeared, although the resting potential remained unmodified. The control for the described experiments is a set of more than 50 micro-injections of pure solvent. After we mastered the technique, the few failures we had were always when we were introducing the pipette, never at the time of withdrawal, that is, during injection. In fact, our experience tells us that large changes in state of the axoplasm have no immediate effect on impulse genesis (see also ref. 6). This was not true of the membrane, since every time we touched it from the inside, the action potential was abolished.

PATHOLOGY

A Quantitative Assay for the Number of Murine Lymphoma Cells capable of Proliferation *in vivo*

Till, McCulloch and Becker[1,2] have demonstrated that normal mouse hæmatopoietic tissue contains a class of cells which are characterized by their ability individually to give rise to macroscopic colonies in the spleens of heavily irradiated recipient mice. The ease with which the colonies may be enumerated has permitted quantitative investigations of the effects of irradiation[3,4] transplantation[5], and erythropoiesis[6] on the number of cells with colony-forming potentiality. These varied applications suggested to us that the spleen-colony technique might be fruitfully applied to the examination of malignant tissue. The results show that a quantitative assay of the number of murine lymphoma cells capable of proliferating *in vivo* is, indeed, possible.

Colonies macroscopically similar to those described by McCulloch and Till have been found to develop in the spleens and kidneys of normal unirradiated mice injected with murine lymphoma cells. The colonies have been demonstrated by the following procedure.

A well-dispersed suspension of lymphoma cells containing very few clumps is prepared from the thymus of a female *AKR/J* mouse 8–12 months old with spontaneous leukæmia by mincing the organ finely with scissors and washing the cells through a fine stainless steel wire mesh with *CMRL* 1066 (ref. 7) medium. The number of

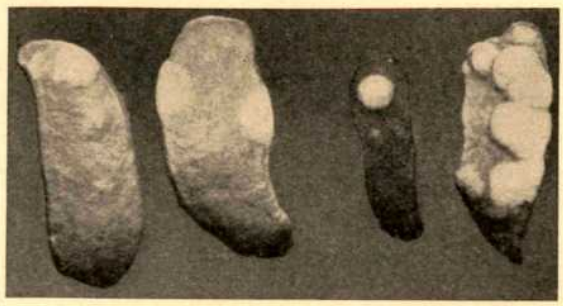

Fig. 1. The spleens of *AKR/J* mice injected 10 days previously with 10^5 lymphoma cells that display the colonies described in the text. Spleens on the left are from unirradiated animals, those on the right are from animals irradiated prior to injection to a dose of 850 rads

nucleated cells in the suspension is determined with a hæmocytometer and, after appropriate dilutions are made, 10^2–10^5 of the cells are injected intravenously into normal, unirradiated, 6–12-week-old mice of the same strain as the donor. The injected animals are killed from 8–12 days later and their spleens removed and placed in Bouin's fixative. Certain of the spleens contain discrete yellow nodules easily visible to the unaided eye (Fig 1, left). They may vary in size from 1 to 6 mm; they usually bulge very slightly from the splenic substance, and their borders may be distinct or very diffuse. The nodules first appear 7–10 days following the injection and then increase in size until they finally involve the entire spleen. The spleens of mice injected with larger numbers of cells frequently do not display any nodular appearance due to the confluence of adjacent nodules. Microscopically the discrete nodules appear as colonies of lymphoid cells quite different from the myeloblast- and erythroblast-containing colonies observed following the injection of bone marrow, spleen or fœtal liver cells into irradiated mice. While the cells in the colonies may differ considerably in appearance from one lymphoma to another, most display prominent nucleoli and many are in mitosis (Fig. 2).

Colonies have been observed in *AKR/J* mice when the cell suspensions used were obtained from *AKR/J* animals with transplanted lymphoma and *C3Hf/BiOci* and (*AKR/J* × *C3Hf/BiOci*) F_1 hybrid mice with Gross virus-induced lymphoma. No colonies have been seen following the injection of as many as 10^7 thymus cells from adult *AKR/J* mice without microscopic evidence of lymphoma.

The nature and origin of the colonies were investigated as follows: Cell suspensions were prepared from five discrete colonies dissected out of the spleen and were injected as a concentrated suspension into normal young

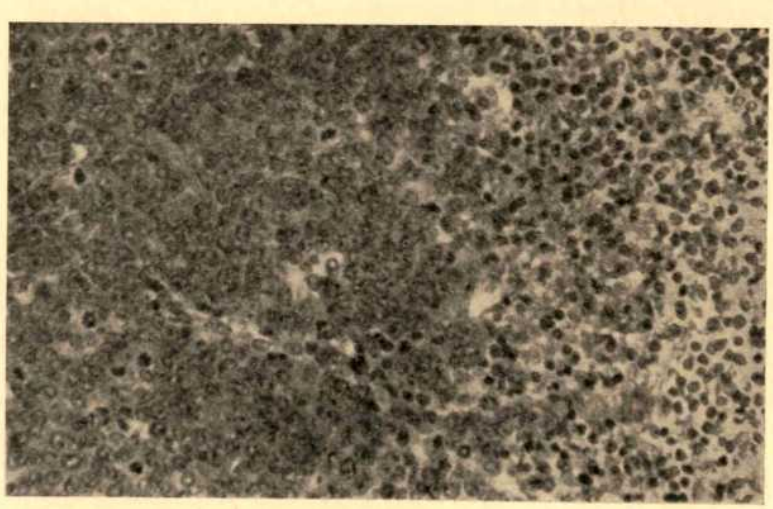

Fig. 2. The border between the colony (left) and the normal splenic tissue (right). The lymphoid cells comprising the colony display prominent nucleoli; many are in mitosis

mice. This resulted in the death of the recipients with widespread lymphomatous disease in less than 14 days, thus showing that the colonies contain malignant cells. Colonies were not observed in mice injected with heavily irradiated lymphoma cells (5,000-rads cobalt-60 γ-radiation, 250 rads/min, cells at 5° C). However, irradiation of the recipient mice (900-rads cobalt-60 γ-rays, 50 rads/min) before the injection of unirradiated cells did not alter the number of colonies observed (Fig. 1, right). Since it is well known that radiation doses of this magnitude destroy the proliferative capacity of the vast majority of mammalian cells[8], these results show that colony formation represents the multiplication of the transplanted malignant cells and not that of the host cells.

The variation in the number of colonies as a function of cell number was examined by injecting groups of 10 and 20 normal and irradiated mice with different numbers of cells. The average number of colonies per spleen obtained for each group for one typical experiment is shown in Fig. 3. The number of colonies increases with cell dose and appears to vary linearly over the range 50–400 cells with a slope corresponding to 130 ± 18 and 123 ± 12 cells injected per spleen colony observed for the normal and irradiated recipient respectively. The linearity is compatible with the assumption that each of the colonies arises from a single injected malignant cell and suggests that the experimental procedure might meaningfully be used to determine the number of colony-forming lymphoma cells in any cell suspension.

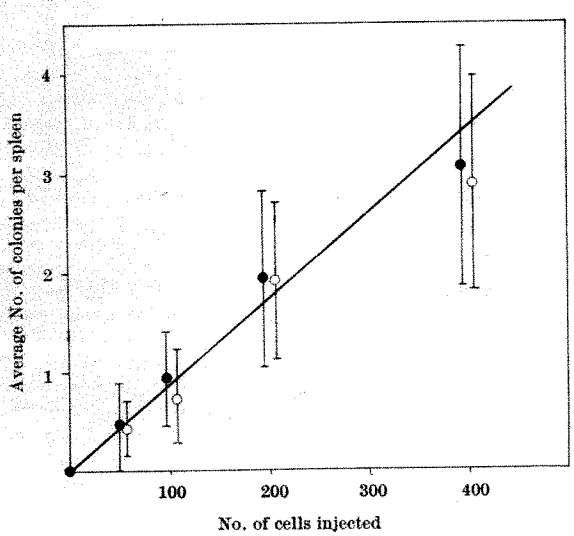

Fig. 3. The average number of colonies observed in the spleen as a function of the number of injected lymphoma cells. 95 per cent confidence limits are given for assays in both normal and heavily irradiated recipients. ○, Unirradiated recipients; ●, irradiated recipients

Thymus suspensions were prepared from 15 female *AKR/J* mice with spontaneous lymphoma and injected in appropriate numbers into groups of unirradiated recipients. The average number of cells which had to be injected in order to observe an average of one colony per spleen varied considerably. The values obtained were : 10^2, 10^2, 10^2, 10^2, 2×10^2, 2×10^2, 5×10^2, 10^3, 10^3, 10^3, 10^4, 10^4, 10^4, 3×10^4, and 10^5. Eight assays on 3 cell lines serially transplanted in *AKR/J* yielded consistently lower values of 30, 10^2, 10^2, 2×10^2, 2×10^2, 3×10^2, 3×10^2 and 3×10^2, cells injected per spleen colony observed. Since no correction has been made for the possibility that some of the colony-forming cells might come to rest in organs other than the spleen, the actual number of these cells must make up well over 1 per cent of the cells injected in some of the suspensions. Many of the spontaneous leukæmias, however, must contain only a fraction as many colony formers.

The procedure described here thus provides a method for obtaining a quantitative assay for the fraction of cells in murine lymphomas capable of proliferation *in vivo*. While it is probably less sensitive than the method of limiting dilution used by Hewitt and Wilson[9], it is certainly much more rapid. Of most importance, however, is the fact that this method permits one to obtain much more information per animal than is possible by the quantal 'alive or dead' response scored by the former method. If the clonal origin of the colonies suggested by the present results is established by further investigations, the method will, in addition, provide a rapid method for obtaining clonal lines of lymphoma cells.

We thank Dr. A. A. Axelrad for his advice, Drs. J. E. Till and E. A. McCulloch for many discussions, and Miss Irene Gyorffy and Mr. B. Meeker for assistance. This investigation was supported by the National Cancer Institute of Canada.

Changes in Resistance to the Proliferation of Isotransplanted Gross Virus-induced Lymphoma Cells, as measured with a Spleen Colony Assay

Klein *et al.*[1] have shown that a state of relative resistance against the isotransplantation of Gross virus-induced lymphomas could be built up in *C3H* mice by treatment with cells from lymphomas originally induced by the same virus. Sera from such resistant mice were shown by Slettenmark and Klein[2] to be cytotoxic *in vitro* for the cells of many Gross virus-induced lymphomas. These findings suggested that lymphomas induced by Gross virus possess tumour-specific antigen, and furthermore that the same antigen is present on the cells of all or most lymphomas induced by this virus.

Examination of foreign antigens in lymphoma cells would be facilitated if a simple method were available for measuring resistance to the proliferation of transplanted lymphoma cells. In this communication, a method is described which appears to be capable of measuring such resistance. Using this method, we have confirmed the findings of Klein's group, and shown that virus extracts of lymphoma cells, as well as lymphoma cells themselves, when given to adult mice, cause a reduction in the proportion of transplanted lymphoma cells which proliferate in their isologous hosts. Furthermore, we have shown that when similar extracts are given to new-born mice, they cause an increase in the proportion of lymphoma cells which can proliferate when isotransplanted into these hosts later in life.

The method is based on the following: Bruce and van der Gaag (preceding communication) found that viable lymphoma cells, injected intravenously into normal, genetically compatible mice, proliferate in spleen and kidneys to form macroscopic colonies that can be counted. Using cells from spontaneous *AK* lymphomas injected into *AK* hosts, they showed that the number of colonies produced in the spleens was proportional to the number of cells injected. The ratio of the number of spleen colonies

observed to the number of cells injected thus serves as a measure of the fraction of cells in any suspension capable of proliferation after transplantation into isologous hosts. Any change in resistance against isotransplanted lymphoma cells should be reflected in a corresponding change in the fraction of cells capable of proliferation, as estimated by the spleen colony assay. If this were so, the spleen colony assay would provide a simple means of measuring the level of resistance against the proliferation of lymphoma cells under a wide variety of conditions.

To test this, we examined the effect of repeated sub-lethal doses of lymphoma cells, isotransplanted intraperitoneally in *C3H* hosts, on the number of colonies formed from a subsequent intravenous challenge of similar cells. The lymphoma cells were obtained from 3–4-month-old female *C3Hf/BiOci* mice injected as infants with Gross passage *A* virus. Cell suspensions were prepared, from enlarged thymuses and lymph nodes, in Krebs–Ringer-phosphate medium with added gelatin and antibiotics. The hosts were *C3Hf/BiOci* adult mice of both sexes, no more than 2 inbred generations removed from the donors of the lymphoma cells. Eleven adult mice, which had not succumbed after 4½ months to the intraperitoneal injection of 10^3 viable *C3H* lymphoma cells, were re-injected with 10^5 cells from another lymphoma, and again 3 months later with 10^4 cells from another lymphoma. Six days after the last injection, these animals were challenged intravenously with 5×10^6 viable (erythrocin-unstained) cells from still another lymphoma. Thirty-six uninjected control mice of the same age received the same challenge dose of cells from the same lymphoma. Twelve days later, the animals were killed, their spleens placed in Bouin's fluid overnight, after which the colonies in the spleens were scored.

The results (Fig. 1) showed that pretreatment of adult *C3H* mice with repeated sub-lethal doses of viable lymphoma cells from isologous donors caused a 7-fold

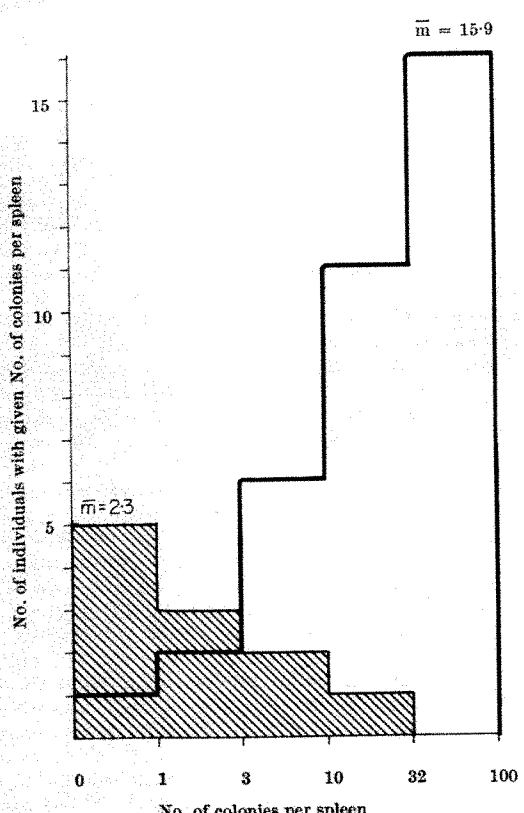

Fig. 1. Effect of pretreatment of *C3H* hosts with sub-lethal doses of isologous lymphoma cells on spleen colony-forming efficiency of *C3H* lymphoma cells. White, untreated control hosts; hatched, hosts pretreated with sub-lethal doses of lymphoma cells

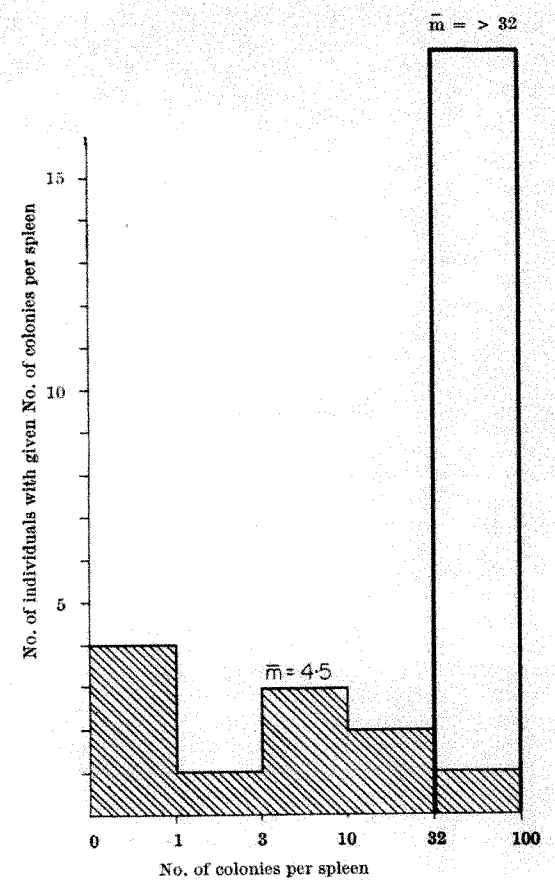

Fig. 2. Effect of pretreatment of *C3H* hosts with Gross virus extract on spleen colony-forming efficiency of *C3H* lymphoma cells. White, untreated control hosts; hatched, hosts pretreated with one dose of Gross virus extract 6 days before cell challenge

reduction in the number of colonies which formed in the spleen. Thus the system used here seems to be suitable for the quantitative investigation of resistance against the transplantation of lymphoma cells in isologous mice. The results are also consistent with those of Klein *et al.*[1] in that they demonstrate inhibition of lymphoma cell proliferation by, and cross-resistance among, the cells of different lymphomas induced by Gross virus.

Next, because Gross virus-induced lymphomas are known to carry the causative virus in infectious form, we examined the effect on the colony-forming efficiency of lymphoma cells of injecting isologous hosts with Gross virus extract before cell challenge. Virus extracts were prepared in the same way as those used for lymphoma induction[2]. Eleven *C3H* mice were given 0·2 ml. of extract intraperitoneally 6 days before challenge with lymphoma cells. Eighteen controls were uninjected before challenge. Both groups received 10^7 cells intravenously. The results (Fig. 2) show that pretreatment with a single intraperitoneal dose of virus extract 6 days before challenge caused a reduction in the number of colonies which formed in the spleen comparable with that seen after repeated injections of sub-lethal doses of lymphoma cells from isologous donors (Fig. 1).

The phenomenon of reduction in spleen colony number resulting from pretreatment with virus extract has been consistent in 9 out of 10 experiments with different lymphomas; the magnitude of the reduction in colony-forming efficiency, when extract was given 6 days before challenge, varied from 7- to 30-fold in different experiments. The effect on spleen colonies could also be detected even when virus extract was mixed with the challenge-cell inoculum. The action of virus extract was also observable on colony formation in the kidneys; the

number of kidney colonies in animals pretreated with virus extract was regularly lower than in controls.

Sachs[4] has shown, by standard methods, a similar inhibition of growth on transplantation of a Moloney virus-induced leukæmia cell line in isologous hosts pretreated with an extract of cultivated leukæmic cells containing the Moloney virus.

From these results, which show that a relative resistance to the iso-transplantation of lymphoma cells can be readily built up in *C3H* hosts by Gross virus-induced lymphoma cells or extracts of these cells, it is reasonable to assume that Gross virus extract is able to stimulate a response in the host similar to that induced by injection of lymphoma cells. This could occur, for example, if virus in the extract caused the transformation of cells in the adult host so that the cells developed a foreign antigen, the host's immune response directed against this antigen would also destroy any transplanted lymphoma cells that have the same antigen. (This hypothesis would be like that proposed by Habel[5] and by Sjögren[6] to account for the fact that infection of adult mice or hamsters with polyoma virus causes these animals to resist the growth of polyoma virus-induced tumour cells isotransplanted into them.) Alternatively, the virus particles themselves (and/or material in the extract) could share the same foreign antigen(s) with the lymphoma cells. Pretreatment with virus extract containing the antigen would stimulate the immune response of the host, which would then also destroy the challenge lymphoma cells. This could be the case, for example, if the new antigen induced by the virus in the course of lymphoma induction were at the surface of the cell. Since the Gross virus is believed to bud from the cell surface, it could carry away the antigen with it on leaving the cell. The observed cross-resistance among different lymphomas, as well as the resistance induced against different lymphomas by the same virus extracts, could thus be explained by the fact that the virus considered responsible for inducing the foreign antigen(s) (and the lymphomas) continues to multiply in the lymphoma cells.

If the resistance built up in *C3H* adult mice by exposure either to cells or to virus extract is indeed due to an antigen foreign to the host, it should be possible to induce immunological tolerance to the antigen in new-born hosts. To test this, a group of *C3H* mice was given 0·2 ml. of Gross virus extract intraperitoneally at 21 days of age, 6 days before cell challenge; a second group was left untreated; a third group was given either 1 dose of 0·08 ml. of Gross virus extract intraperitoneally within 24 h of birth or 1 dose at birth and 1 dose each week thereafter for 3 weeks (0·1, 0·1 and 0·2 ml.). All 3 groups were challenged at 4 weeks of age with 10^6 cells from one lymphoma. In addition, a group of controls and a group that received virus extract at birth, or at birth and once weekly for 3 weeks, were also given, intravenously, 3×10^4 cells from the same lymphoma. Finally, a control group was included that received virus extract at birth but no cell challenge. The results were identical in mice given 1 or 4 doses of virus extract from birth, and so these results have been pooled.

Table 1 shows again the reduction in number of colonies produced by lymphoma cells in mice that received virus extract for the first time at 6 days before cell challenge. Table 1 also illustrates rather strikingly that when virus extract was injected into new-borns which were then challenged later in life, a considerably larger number of colonies was produced from the same inoculum of lymphoma cells in these animals than in controls that had not received virus extract before the cell challenge. Not only did the injection of extract into new-borns fail to induce immunity to the cells as it did when injected into older animals, but the effect of the extract in the new-born, which persisted until the time of challenge 4 weeks later, was instead to interfere with the resistance that the normal host was apparently able to exert on the proliferation of the challenge lymphoma cells. This behaviour has now been observed in 5 out of 5 experiments, the magnitude of the increase in colony-forming efficiency ranging from 2- to 30-fold. It is as if exposure of the new-born to Gross virus extract brought about a state of actively acquired immunological tolerance to foreign antigen(s) on the lymphoma cells originally induced by Gross virus. This situation may be comparable with that described by Rubin[7] in which Rous sarcoma cells grow progressively in chickens rendered tolerant to viral antigen but regress in those that are immunologically competent.

Whatever the precise mechanisms involved, the work recorded here shows that when either Gross virus-induced lymphoma cells or virus extracts of these cells are given to adult mice which are then challenged with lymphoma cells from isologous donors, the hosts respond by causing *a reduction* in the fraction of the transplanted cells that are capable of proliferation. When, however, Gross virus extracts are given to new-born mice which are challenged with isologous lymphoma cells later in life, they respond by causing *an increase* in the fraction of these cells that are capable of proliferating in them.

Table 1. Effect of Injecting Gross Virus Extract into 3-week-old and < 1-day-old *C3H* Mice on Number of Spleen Colonies after Intravenous Challenge at 4 Weeks of Age with Lymphoma Cells from Isologous Donors

Experiment			Results					
Treatment	No. of cells injected at 4 weeks	Total No. of hosts	No. of hosts with given No. of colonies in spleen					Mean No. of colonies per spleen
			0	1–3	4–9	10–31	32+	
Virus extract at 3 weeks of age	1×10^6	9	8	1				0·11
Uninjected controls	1×10^6	10	3	2	1	1	3	3·3
Virus extract on day of birth	1×10^6	12					12	>32
Uninjected controls	3×10^4	10	8	2				0·2
Virus extract on day of birth	3×10^4	12	3	4	5			3·0
Virus extract on day of birth	0	6	6					0

It should be pointed out that great variations were found in the colony-forming efficiencies of individual lymphomas independently induced by Gross virus in different *C3H* mice and assayed under apparently identical conditions. The number of cells required to produce an average of 1 colony per spleen varied over a 10^4-fold range; most often it was around 6×10^5 cells. This fact must at present be left unexplained.

In earlier work[8,9], the suggestion was made that induction of lymphoma in *C3H* mice by Gross virus requires the presence of relatively undifferentiated cells proliferating and differentiating in the cortex of the thymus; the present observations would indicate that the animal might also have to become 'tolerant' to the foreign antigen(s) on the induced lymphoma cells. This also raises the question as to whether the cells of 'spontaneous' neoplasms possess foreign, tumour-specific antigens. In a number of experiments using systems *in vivo* that were capable of detecting tumour-specific antigens in a variety of induced neoplasms, no evidence was found for the presence of such antigens in 'spontaneous' tumours[10–12]. But the methods used in these experiments have depended on an immune reponse of the host for detecting tumour-specific antigens. If there were any impairment in the responsiveness of the host to such antigens, then it would be impossible to detect tumour-specific antigens by these means. Therefore in situations where tumour cells behave as if they do not possess foreign antigens, the possibility should be considered that such antigens may be present but not detected because the hosts may have become tolerant to antigens

on their tumour cells as a result of some event that preceded the maturation of their immune mechanisms.

I thank Mr. H. C. van der Gaag for his assistance. I also thank Dr. A. W. Ham and Dr. L. Siminovitch for help with the manuscript. This work was supported by grants from the National Cancer Institute of Canada and the National Cancer Institute, U.S. National Institutes of Health.

A Stochastic Model of Carcinogenesis compared with Mouse Skin Tumour Enhancement after Gastric Instillation of 9,10-Dimethyl-1,2-Benzanthracene with Subsequent Local Continuous Exposure to 'Tween 40'

A FAIRLY good agreement has been found between a stochastic model[1,2,5], and a skin tumour production experiment performed by Berenblum and Shubik[3]. In this experiment development of the skin tumour after a single local exposure of mouse skin to graded concentrations of 9,10-dimethyl-1,2-benzanthracene (DMBA) with subsequent twice-weekly exposure of the same skin area to croton oil was investigated. Since then it has been shown that systemic (oral, intravenous, intraperitoneal) initiation and subsequent local tumour enhancement provokes skin tumours[4] (for further references, see ref. 7), and a new and physicochemically well-defined group of tumour-enhancers, the dipole-type compounds, has been established[17] (for a comprehensive review, see ref. 8).

The essential importance of the so-called frequent-application technique (that is, maintaining a continuous contact between the target cells and the tumour-enhancing compound) has also been demonstrated[6]. Furthermore, it has been shown that the responses of mouse skin to treatment with carcinogens and dipole-type tumour-enhancers fundamentally differ from each other[9–12,18], at least in a skin-tumour-resistant mouse strain[13–16] (that is, a mouse strain responding by formation of no or very few skin tumours to treatment with dipole-type tumour enhancers or to mechanical wounding of the skin, unless initiated with a carcinogen). These improvements of the two-stage technique could be supposed to provide a greater consistency with the premises of the stochastic model[1,2,5], namely, a uniformly randomized distribution of the carcinogen and a constant concentration of the tumour enhancer together with the absence of an inherent tumour-susceptibility of the experimental animals.

It thus seemed interesting to compare the stochastic model with experimental results recently obtained[7] with gastric instillation of different doses of DMBA to mice and subsequent continuous local exposure of the skin to

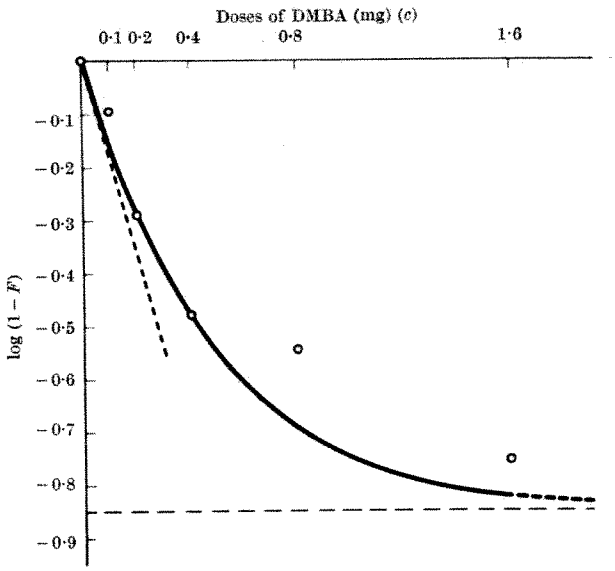

Fig. 1

'Tween 40' (polyoxyethylene sorbitan monopalmitate), a dipole-type tumour enhancer.

In each mouse of 5 groups of 50 female albino animals of the skin-tumour-resistant *RA* strain 1·6, 0·8, 0·4, 0·2, and 0·1 mg, respectively, of DMBA in 0·15 ml. of 'Carbowax 400' (polyethylene glycol 400) were injected in single intragastric dose[7]. After an interval of 30 days the hair on the back of the mice was cut, and local exposure 6 times a week to undiluted 'Tween 40' started for 38 weeks. The numbers of survivors, the numbers of tumour-bearers (n), and the numbers of tumours per tumour-bearer (M) were recorded at weekly intervals, as well as the induction time (t) for each tumour (that is, the time-interval between commencement of exposure to the tumour enhancer and the first appearance of the skin tumour). The tumour incidence in each experiment was calculated as the ratio between the number of tumour-bearers (n) and the number (n_0) of animals alive when the first tumour appeared in that experiment. From the expression $F = n/n_0$ obtained at the end of the experiments the quantities $\log(1 - F)$ were calculated and plotted versus the dose c of the carcinogen γ (Fig. 1). According to the stochastic model of carcinogenesis[2]:

$$\log(1 - \bar{F}) = -\beta(1 - \exp[-\gamma c])$$

where $\bar{F}$ is the theoretical value, that is, the mean tumour incidence, c the dose of the carcinogen, and β and γ two parameters to be estimated from the experiments. These parameters can be estimated graphically from the experimental values plotted in Fig. 1 as described in ref. 2, and yields the numerical values $\beta = 0{\cdot}85$ and $\gamma = 2{\cdot}12$ mg^{-1}. From these results can also be calculated the theoretical value $\bar{t}$ of the induction time t as described in ref. 2. The result is shown in Fig. 2 together with the experi-

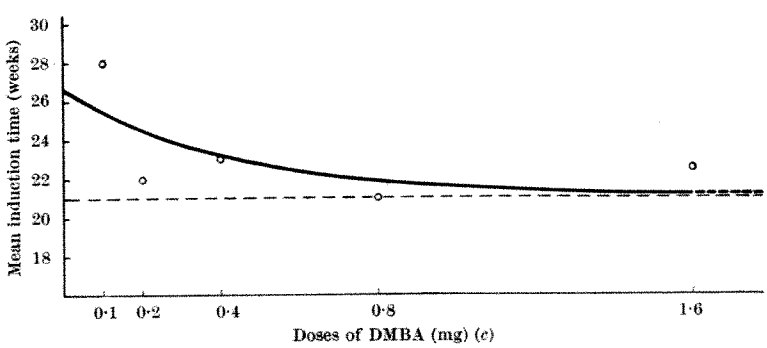

Fig. 2

mentally observed average induction times versus doses c.

As seen from the results in Figs. 1 and 2, the experimental and theoretical values of the incidences and of the induction times are in good agreement with each other. However, a closer analysis shows that the experimental values ($\bar{M}$) of the mean numbers of tumours per animal deviate somewhat from those expected from the stochastic model, calculated as described in ref. 2; but as discussed in refs. 1 and 2 there are several sources of error in the observation of M such as, for example, the fact that some tumours may have disappeared before being observable, etc. Also the individual tumours on the same animal may not have arisen independently of each other as assumed in the stochastic model. On the whole we think, therefore, that our results give new evidence in support of the somatic mutation hypothesis of carcinogenesis in its direct one-hit form discussed in ref. 1, as well as of the view previously expressed that carcinogens primarily cause a delayed maturation of the epidermal cells and that subsequent exposure to a dipole-type tumour enhancer, despite increase in the rate of mitosis, will in these circumstances not lead to the formation of an adequate amount of normally differentiating cells[7,10,18]. The ultimate result is the formation of a focal epidermal tumour.

Skin Reaction in Children and Adults with Central Nervous System Disease after Intracutaneous Administration of Myelin Preparations derived from Human Brain

Much of the available experimental evidence[1,2] suggests that pathological demyelination in the human brain might occur as a result of a delayed-type hypersensitivity reaction against myelin[3,4], although a significant role of circulating antibody cannot be altogether ruled out[5,6]. Previously[7,8] we reported that we had been able to elicit a skin reaction against proteolipid A derived from human brain in 21 cases of multiple sclerosis and two patients with clinically diagnosed neuroses which was in agreement with the results obtained by other investigators[9,10] who had tested skin reactivity against unpurified human myelin. While the pathognomonic significance of the skin reaction thus remains doubtful we endeavoured to examine the question whether a true hypersensitivity reaction was present or not by comparing a large number of adult patients with a group of children suffering from a variety of central nervous system disorders as to their ability to react against myelin.

Table 1

Diagnosis	No. of cases	Onset of reaction (h)	Min./max. diameter of reaction (cm)
Group *A* (adult patients)			
Multiple sclerosis	22	1–7	0·5–2·1
Transverse myelitis	1	3	1·0
Neuritis	6	2–13	0·5–2·1
Pseudo bulbar paralysis	1	9	1·0–1·8
Amyotrophic lateral sclerosis	3	2–3	0·7–1·9
Syringomyelia	2	5–6	1·2–2·0
Gliosis of cervical cord	2	4	0·8–2·0
Meningioma of cervical cord	1	9	1·0–1·8
Friedreich's ataxia	2	3	0·4–1·7
Extrapyramidal motor system disease	2	1–3	1·0–1·4
Combined system disease	3	1–5	1·8–2·8
Muscular dystrophy	2	5–6	1·6–2·0
Secondary muscular atrophy	1	9	1·6–1·8
Delirium tremens	1	2	1·0
Neuroses	3	2–6	0·6–1·7
Total	52		
Group *B* (adult patients treated with steroids or salicylic acid)			
Transverse myelitis	1	negative	
Multiple sclerosis	1	1	0·5
Sydenham's chorea	1	3	0·3
Total	3		
Group *C* (children)			
Neurosis	2	negative	
Psychomotor seizures	1	negative	
Post-encephalitic syndrome	1	negative	
Sydenham's chorea	1	negative	
Meningoencephalitis	1	negative	
Behavioural disturbance	1	negative	
Psychomotor seizures	1	2	1·2
Inflammatory central nervous system disease	1	negative	
Extrapyramidal motor syndrome	1	negative	
Purulent meningitis	1	negative	
Post-commotional syndrome	1	negative	
Total	12		

Two preparations of myelin were used. The first one was obtained by extracting human white matter with chloroform/methanol following the procedure of Folch and Lees[11]. The second one was produced by ultracentrifugation using the method of Laatsch *et al.*[12]. These preparations were administered in two different concentrations, that is, 0·005 mg/ml. and 0·05 mg/ml. In some children, one half-strength of the first concentration = 0·0025 mg/ml. was used. The preparations were suspended in normal sterile saline and injected intracutaneously in a final volume of 0·2 ml. into the flexor surface of the forearm. An equal volume of saline was given simultaneously into the opposite forearm. In those cases where both myelin preparations were tested at the same time, the second test dose was injected at a distance from the site of injection of saline. At varying time intervals after injection a biopsy from the reaction site was taken under local anæsthesia.

As may be seen from Table 1 (group A) positive skin reactions were observed in 22 patients with multiple sclerosis, 1 with transverse myelitis, 6 with peripheral neuritis or polyneuritis respectively (which was verified at autopsy in one instance), 1 with bulbar paralysis, 3 with amyotrophic lateral sclerosis, 2 with syringomyelia, 2 with gliosis of the cervical spinal cord, 1 with a meningioma of the cervical portion of the spinal cord, 2 cases of Friedreich's ataxia, 2 patients with extrapyramidal motor system disease, 3 cases of combined system disease, 2 cases of muscular dystrophy, 1 case of neural (secondary) muscular atrophy and one patient with delirium tremens. Furthermore, 3 patients without organic brain disease exhibited positive skin reactions. The earliest onset of a reaction occurred after 1 h; but as a rule reddening of the skin was not seen until 2–3 h after injection. The majority of the reactions lasted up to 48 h, some longer. The diameter of the reaction site never exceeded 3·0 cm.

The second (B) group of patients consisted of one case of transverse myelitis, one case of multiple sclerosis and one case of Sydenham's chorea, all of which were under treatment with corticosteroids or salicylic acid respec-

tively. The first patient failed to show a reaction, while the remaining two reacted in the same manner like those listed in group *A*.

In group *C*, 12 children aged between 5 and 14 years were tested. This group was composed of 2 neurotic patients, 2 cases with psychomotor seizures, 1 patient with a post-encephalitic syndrome, 1 case of Sydenham's chorea, 1 patient with meningoencephalitis, 1 case of inflammatory central nervous system disease which so far has resisted diagnostic clarification, 1 patient with extrapyramidal motor system disease, 1 patient with healed purulent meningitis, 1 patient with a post-commotional syndrome and one case undergoing treatment for behavioural disturbances. Except for one of the two cases with psychomotor seizures, no positive skin reactions were observed.

In none of the three tested groups were any discernible differences noted between the two myelin preparations with respect to their ability to bring about the skin reaction. Histologically, the reaction was characterized by widespread œdema of the upper dermis, perivascular accumulation of round cells and granulocytes around the capillaries of the entire dermis and scanty infiltration of the dermis with eosinophilic granulocytes. Vascular distension and perivascular œdema persisted longest while the cellular reaction usually had disappeared after 40 h. The histological picture strongly resembled that obtained in disseminated lupus erythematosus after intracutaneous injection of vascular antigens[13].

The fact that with one exception no positive reaction could be observed in children suggests the possibility that a gradual, physiological demyelination process begins in man at puberty which results in the development of cellular hypersensitivity. While this process must be considered normal it could be imagined that in certain circumstances a modification occurs which would start off pathological demyelination. In order to test this hypothesis, persons without neurological disorders and belonging to younger age-groups are at present being examined.

IMMUNOLOGY

Use of Oxidized Proteins in the Examination of Immunochemical Specificity in Delayed Hypersensitivity to Hapten – Protein Conjugates

Recent investigations of delayed hypersensitivity to hapten–protein conjugates have established clearly the importance of the carrier protein as one of the determinants of specificity[1–3]. Efforts to define further such determinants are hampered to some extent by the heterogeneity of the response to immunization with a hapten–protein conjugate in which many possible antigenic determinants may play a part. In previous work[4], it was shown that oxidation or reduction and alkylation of all disulphide bonds in several proteins (resulting in complete loss of tertiary structure with retention of primary structure) produced the most drastic reduction in the ability of these proteins to precipitate rabbit antibody and to sensitize guinea pigs to delayed hypersensitivity to the native proteins. It was thought that the use of such open chains to serve as hapten carrier might provide valuable information about the relative contributions of folded structure and amino-acid sequence to the specificity involved in delayed hypersensitivity.

This communication describes the results obtained with conjugates prepared by coupling excess diazotized arsanilic acid (ars) and *p*-aminobenzoic acid (benz) to guinea pig serum albumin (GSA) and oxidized guinea pig serum albumin (OxGSA) in cold alkaline solution. The coloured conjugates were dialysed exhaustively and final concentrations determined on the basis of original protein used, assuming no net loss during the chemical reactions.

Guinea pigs were immunized by injection in the 4 footpads of 1 μg N of the conjugate contained in 0·1 ml. of complete Freund's adjuvant (8·5 parts 'Arlacel', 1·5 parts mineral oil, 5 mg/ml. *Mycobacterium tuberculosis*) and skin tested two weeks later with 1 μg N of the appropriate test antigen in 0·1 ml. volume. The average diameter of induration and erythema was measured at 24 h. Desensitization was accomplished by injection of 1 mg of protein intraperitoneally in the morning and 1 mg protein intravenously in the afternoon, followed immediately by the appropriate skin tests.

Table 1. Effect of Changes in Carrier Protein on Ability to Elicit Delayed Reactions in Guinea Pigs before and after Desensitization

Immunized with	No. of guinea pigs	Delayed reactions to skin tests* with 1 μg N: Ars–GSA	Ars–Ox-GSA	Ars–RNase	Ars–Ox-RNase	Benz–GSA
Ars–GSA	6	18	12	9	6	11
	Same after desensitization with 2 mg benz–GSA	17	13	9	8	3
		Ars–GSA	Ars–BSA	Ars–Ox-BSA	Benz–GSA	
Ars–GSA	6	19	11	8	13	
	Same after desensitization with 2 mg benz–GSA	17	12	11	5	

* Induration and erythema in mm

Table 1 presents the results of an experiment to define the role of the carrier protein. When 6 guinea pigs immunized with ars–GSA were skin-tested with the same hapten conjugated to OxGSA, a substantial delayed reaction was noted. This reaction, while less than that for the homologous conjugate (ars–GSA), was in turn greater than that obtained with the conjugates of the heterologous protein ribonuclease (ars–RNase) or its oxidized form (ars–Ox–RNase). In addition, a moderately strong reaction was obtained to a conjugate of GSA prepared with a non-cross-reacting hapten, the azobenzoate group (benz–GSA). Desensitization with this material resulted in a considerable reduction in the delayed skin reaction to the homologous carrier–heterologous hapten conjugate (benz–GSA), but virtually no change with the homologous hapten and either homologous or heterologous carriers (ars–GSA, ars–RNase). A second group of guinea pigs immunized with ars–GSA and tested with the same hapten on an immunologically related carrier, bovine serum albumin (BSA), gave good reactions with conjugates of both the native and oxidized forms. Once again, desensitization with benz–GSA resulted in considerable loss of reactivity attributable to the carrier; but the reactions to the homologous hapten–heterologous carrier conjugates remained unchanged. These results suggested strongly that

one component of the large reaction observed with the immunizing antigen was attributable to a specificity revealed or produced from the carrier protein by reaction with the hapten, since the carrier (GSA) itself is non-antigenic in the guinea pig. When this contribution to the net delayed reaction was removed by desensitization with the carrier protein which had been altered in a similar fashion by conjugation with a non-cross reacting hapten, there was some slight decrease in skin reaction to the homologous material, but virtually no change in reactions to the homologous hapten–heterologous carrier combination.

To define further the relative contributions of the carrier protein and the hapten to the response resulting from immunization with conjugates, four groups of guinea pigs were immunized with 1 μg N quantities of GSA or OxGSA conjugated with either arsanilic acid or *p*-aminobenzoic acid. The results of skin tests performed with all four conjugates shown in Table 2 demonstrate again that in each case the largest skin reaction was obtained with the antigen used for immunization. When the carrier protein was altered by being oxidized to its open-chain form, conjugates prepared with it were still able to elicit a moderately large delayed reaction. Once again, a substantial reaction was obtained with the heterologous hapten on the homologous carrier. These observations strongly support the concept that the larger reaction seen with the immunizing antigen was attributable to participation by antigenic determinants revealed or produced in the protein by the chemical process of conjugation with a diazonium salt. Further evidence that this might indeed be so was seen in skin tests following desensitization with the heterologous hapten–homologous protein carrier conjugate. The almost total abolition of the skin reaction to the homologous carrier–heterologous hapten conjugate was followed in most cases by a slight reduction in skin reactions to the immunizing antigen to the point where oxidized and native forms of the carrier were virtually identical in either the azobenzoate or azobenzenearsonate systems.

Table 2. Effect of Changes in Carrier Protein and Hapten on Ability to Elicit Delayed Reactions in Guinea Pigs before and after Desensitization

Immunized with	No. of guinea pigs	Skin tests* with 1 μg N Ars–GSA	Ars–Ox-GSA	Benz–GSA	Benz–Ox-GSA
Ars–GSA	8	15	10	8	
	5 after desensitization with 2 mg benz–GSA	13	10	3	2
Ars–OxGSA	7	10	13		10
	3 after desensitization with 2 mg benz–GSA	10	10	0	3
Benz–GSA	6	9		14	12
	4 after desensitization with 2 mg ars–GSA	2	0	16	15
Benz–OxGSA	6		10	11	14
	4 after desensitization with 2 mg ars–OxGSA	2	0	9	10

* Induration and erythema in mm

One logical inference to be drawn from these observations is that a large part of the specificity involved in the delayed reaction to the hapten–protein conjugate is a consequence of the amino-acid sequence of the protein carrier, since these were common to both the oxidized and native proteins, while tertiary structure, so important to reactivity of antigens with antibody, played a secondary part. To clarify further the extent of contribution by the amino-acid sequence of the carrier to the immunological specificity of the conjugate, an experiment was performed in which guinea pigs immunized with ars–GSA or benz–GSA were tested with conjugates prepared from a wide variety of proteins in which the likelihood of common amino-acid sequences recurring seemed vanishingly small.

The results of such an experiment, given in Table 3, demonstrate what appears to be a remarkable lack of carrier specificity in evoking a delayed reaction with conjugates prepared from arsanilic acid and are in striking contrast to results obtained with conjugates of *p*-aminobenzoic acid, as has been reported previously with other haptens[3]. Thus, while the largest reactions were always seen with the immunizing antigen, significant positive reactions were seen with conjugates prepared from proteins as immunologically diverse as gelatin, ribonuclease, insulin, and elastoidin.

Table 3. Skin Reactions to Conjugates prepared with Heterologous Proteins in Guinea Pigs immunized with Ars–GSA or Benz–GSA

Immunized with	No. of guinea pigs	Skin tests* with 1 μg N Ars–GSA	Ars–RNase	Ars–gelatin	Ars–insulin	Ars–elastoidin	Ars–poly tyrosine
Ars–GSA	6	17	8				
Ars–GSA	4			11	13	13	10
		Benz–GSA		Benz-gelatin	Benz–insulin		Benz–poly-tyrosine
Benz–GSA	5	17		0		0	0

*Induration and erythema in mm

Furthermore, since conjugates prepared from carriers containing little tyrosine (gelatin) or much tyrosine (poly-tyrosine) were equivalent in eliciting reactions, it seemed most probable that a large measure of specificity is conferred by the azobenzenearsonate group alone. This is in striking contrast to results obtained by other workers[1,3] and by myself with similar haptens, such as the azobenzoate group. In the latter case, conjugates prepared with other proteins were unable to elicit positive reactions in guinea pigs sensitized with benz–GSA. Because of this striking difference between results obtained with the azobenzenearsonate and the azobenzoate radicals, the whole question of the part that size of hapten plays in determining specificity in delayed hypersensitivity is thrown into bold relief and is at present under active investigation.

A second point of interest concerns the observation that conjugates prepared with oxidized GSA are essentially equivalent to those prepared with native GSA in eliciting delayed reactions in guinea pigs which have been desensitized to those determinants arising from the GSA through the effects of chemical reactions. The implications of this observation are that the contributions made by the carrier protein to the antigenic determinant, of which the hapten is a part, are attributable to its primary rather than tertiary structure. To explain the non-reactivity of unrelated carriers conjugated with the smaller haptens, it only becomes necessary to invoke the involvement of a sufficient number of amino-acid residues to provide unique sequences available only in the homologous protein.

In the light of experiments and reports so far given, it is now possible to think of the heterogeneity of response to immunization with hapten–protein conjugates as involving three main categories of antigenic determinants: (1) those produced or revealed in the protein carrier by chemical manipulation; (2) those consisting of the hapten plus the amino-acids immediately adjoining its site of attachment; (3) perhaps in special cases (as with the azobenzenearsonate group) those consisting largely of the hapten alone. Further work should show whether the degree of complementary form involved is in all cases equivalent with different contributions being made by various haptens and amino-acids in an additive fashion until some minimal value necessary for the delayed reaction to occur is achieved in any particular hapten-carrier system.

Duration of Antibody Response to Soluble Antigen

ANTIBODY production after immunization with particulate antigens is known to persist over long periods of time. By contrast, immunization with soluble antigens in the absence of adjuvants is generally thought to give responses of relatively brief duration. Recently, it has been reported that antibody production continued for several hundred days in rabbits given one or several intravenous injections of a number of soluble antigens[1]. Antibody produced late in the course of the response gave negative ring tests, failed to sensitize the guinea pig intestine, and could be detected only by a passive hæmagglutination technique. This communication is concerned with similar observations on the response of chickens to intravenous injections of bovine serum albumin (BSA). One major finding of this study is the persistence of precipitating antibody up to 313 days after injection.

Antisera were obtained at various times after two spaced (50 days) intravenous injections of BSA (40 mg/kg body-weight). Antibody activity was measured both by precipitin tests and by Farr's technique[2], which depends on the differential solubility of free ^{131}I-BSA and ^{131}I-BSA bound to antibody in half-saturated ammonium sulphate. The dilution effect, 'avidity', was determined by comparison of the antigen-binding capacity of serum at two concentrations of BSA. The antigen-binding capacity was determined as described by Farr: sera were diluted until 33 ± 10 per cent of a constant amount of antigen was precipitated after addition of ammonium sulphate. Correction factors were applied to normalize all values to 33 per cent binding. The following formula was used to calculate the antigen-binding capacity: (μg BSA nitrogen added/ml.) × (0·33) × (reciprocal of dilution binding 0·33 of added antigen).

The antigen-binding capacities of the three animals tested were remarkably constant over the 226-day period considered (Table 1), the only difference noted being an increase in 'avidity' between 87 and 241 days after immunization. Because all samples were tested at the same time, this avidity difference may represent an effect of storage. According to Farr[2], complexes formed at the 0·33 reference point with high avidity sera have an overall molar ratio of one antibody molecule to two antigen molecules. The weight ratio of BSA (mol. wt. 70,000) to antibody (160,000) in such complexes would be essentially one. Thus, the antigen-binding capacity of high-avidity sera approximates the actual antibody content, provided one is testing bivalent antibody. The precipitating antibody concentrations expected in the sera under investigation then would be 4–10 μg nitrogen/ml., clearly less than the resolving power of most quantitative precipitin methods.

Table 1. ANTIGEN-BINDING CAPACITY (ABC)* AT VARIOUS TIMES AFTER IMMUNIZATION

Bird No.	Days after second injection			
	87	241	297	313
28	0·93/1·6 (58)	1·4/1·8 (78)	1·5/2·0 (75)	1·2/1·7 (71)
29	1·4/2·4 (58)	1·2/1·7 (71)	0·90/1·3 (69)	1·2/1·6 (75)
30	0·54/1·1 (49)	0·72/1·1 (65)	0·93/1·4 (66)	0·74/1·1 (67)

* The figures given are: ABC at 0·16 μg BSA nitrogen per ml./ABC at 1·6 μg BSA per ml. (percentage 'avidity'). ABC values calculated for 0·25 ml. serum.

Because of the contention[1] that late antibody is non-precipitating, experiments were carried out to test rigorously for the presence of precipitating antibody. Mixtures of serum and ^{131}I-BSA of varying concentrations were made in both 0·9 and 8 per cent sodium chloride. The mixtures were incubated at 37° C for 6 h and then at 5° C for several days. The radioactivity of each tube was determined in a well-type scintillation counter both before and after centrifugation and removal of the supernatant fluid. In this manner, it was possible to detect significant precipitation of antigen in the absence of any readily visible precipitate. Control tubes containing antibody to a non-related protein retained less than 2 per cent of the added antigen, even in the absence of washing.

In all samples tested, complete antigen precipitation occurred over a wide range of concentrations (Fig. 1) and, significantly, at high enough concentrations to account completely for the antigen-binding capacity data. Because this method allows fairly accurate delineation of the region of slight antigen excess, it is also possible to estimate antibody content based on known equivalence ratios of antibody to antigen. Such estimates of antibody content were generally several times higher than the estimates based on the antigen-binding capacity. This is not entirely unexpected because the avidities of the sera were less than 100 per cent, that is, higher antigen-binding capacity values would be expected if higher concentrations of antigen were used. These results show that the late antibody response of chickens consists mainly of precipitating antibody. Because of evidence[3] indicating that non-precipitating antibody is not responsible for passive hæmagglutination reactions, it is expected that the use of more sensitive methods also would reveal the presence of precipitins in the late response rabbit antisera[1].

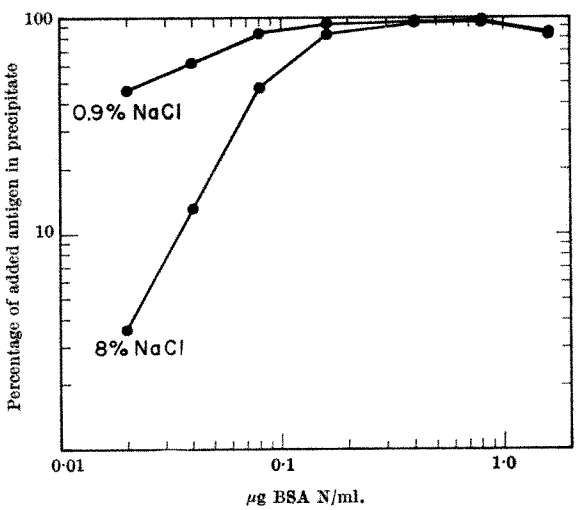

Fig. 1. Bird 29, 297 days after injection. Approximate equivalence concentration, 0·8 μg nitrogen/ml. Note marked inhibition by 8 per cent sodium chloride in antibody excess region

Although not directly related to the main point of this communication, the occurrence of a marked inhibition zone in extreme antibody excess deserves comment. As shown in Fig. 1, inhibition of antigen precipitation was greatest in the presence of 8 per cent sodium chloride. This is surprising, because it is well established that maximum precipitation occurs at this salt concentration with avian antisera. By adding ammonium sulphate to one-half saturation, all the antigen could be precipitated from the supernatants in this region. Therefore, the primary interaction between antigen and antibody was not affected.

BIOLOGY

Electric Receptors in a Non-electric Fish (*Clarias*)

It is now well established that certain fish can detect objects electrically. These fish have weak electric organs, and set up an electric field in the surrounding water. A nearby object distorts this field, and the distortions are detected by the fish. The electric receptors are sense organs communicating with the water by means of jelly-filled canals.

In an early examination[1] of this 'electric sense' we suggested that the incoming electrical signals were 'smoothed' at the electric receptors before being coded into impulses in the afferent nerves. This hypothesis was tested in a series of experiments[2] in which a *Gymnarchus niloticus* was trained to respond to an applied electric field. The hypothesis was fully confirmed; the smoothing time-constant was found to be about 25 msec. It was further found that the fish was unexpectedly sensitive to trains of pulses of low-repetition frequency; this suggested that adaptation of the receptors was taking place with a time constant of some tens of milliseconds. Each successive pulse of the train would then give rise to a separate sensory signal. If the time taken in the central nervous system to process the sensory data and release the response (the 'perception time') were sufficiently long, several of these separate signals might be centrally summated to form a larger stimulus.

All the species of the two families of fish examined so far (Mormyridae, Gymnotidae) possess electric organs and specialized electric receptors derived from the lateralis system. On evolutionary grounds there is reason to suppose that some non-electric fish may have electric receptors[3], and that knowledge of their properties may help towards an understanding of the mechanism of electric receptors in general[4].

For our experiments an African species of *Clarias*—belonging to the very large catfish family (Siluridae)—was chosen for the following reasons: (*a*) One species of this family is known to be electric—the strong electric *Malapterurus*; no connecting link to non-electric catfish has been established through a weak electric species. (*b*) A number of members of this family (*Clarias*, *Saccobranchus*, *Malapterurus*, *Amiurus*, *Silurus*, etc.) were found to respond to a moving magnet. (*c*) Freshwater catfish possess 'small pit organs' structurally reminiscent of 'mormyromasts'; one marine species has ampullæ of Lorenzini, receptors known to be sensitive to electric currents in the Elasmobranchs[5–7]. (*d*) In life habits and ecology many catfish resemble the mormyrids and gymnotids.

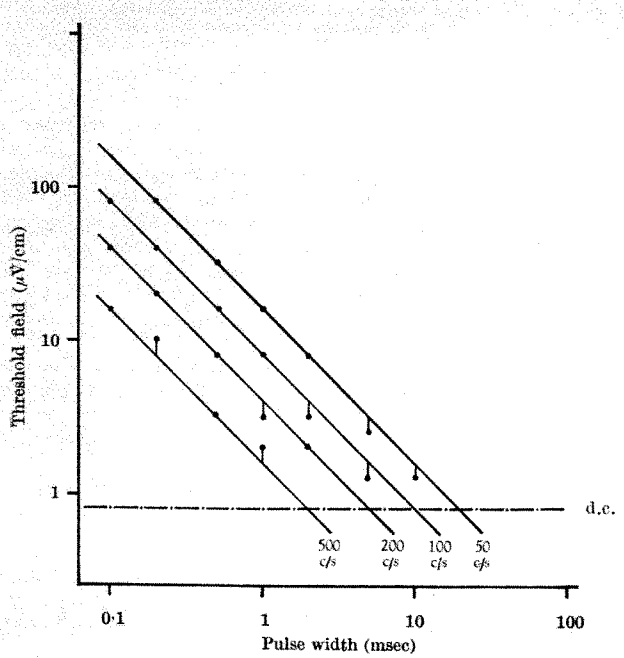

Fig. 1. Threshold field for the 'standard response' by *Clarias* to trains of pulses from 50 c/s to 500 c/s, and also to d.c.

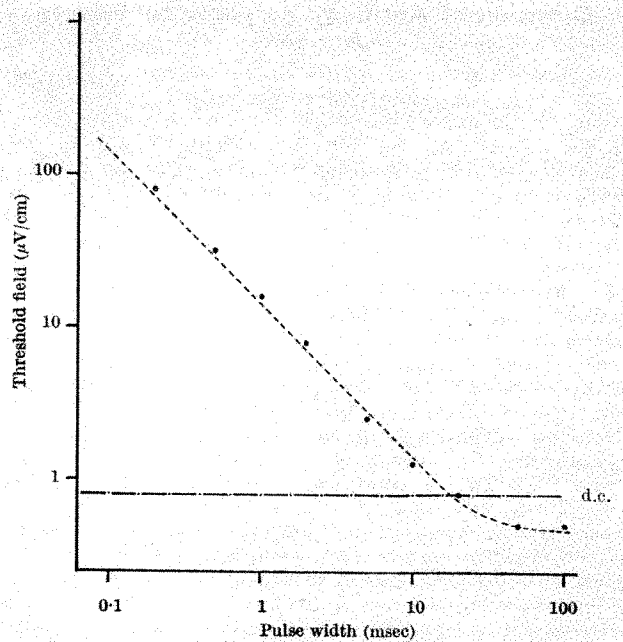

Fig. 2. Threshold field for single pulses

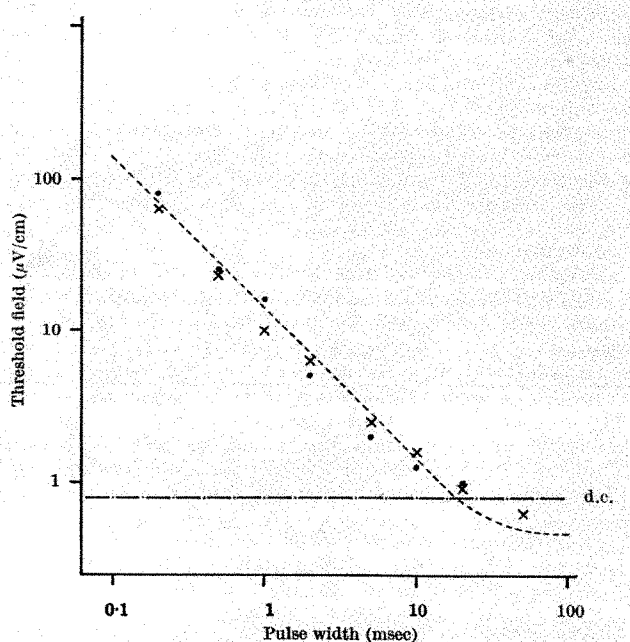

Fig. 3. Threshold field for low-frequency pulse trains. ●, 20 c/s; ×, 10 c/s; – – –, single pulses

The experimental procedure followed that used for *Gymnarchus*[2]: a specimen of *Clarias* (*anguilloides*?) was confined within a tank fitted with two electrodes between which an electric field could be established. The input to the electrodes was of controllable amplitude, and could be either d.c., single pulses or trains of pulses. The fish was trained to give 'a standard response' when the electric field was applied; the threshold field required to elicit this response was measured for the various types of stimulus.

The results for pulse trains of relatively high frequency, and for d.c., are shown in Fig. 1. As with *Gymnarchus*, the threshold is determined only by the mean value (or 'd.c.

content') of the field. Smoothing of the electrical signal is clearly taking place; from the results with single pulses (Fig. 2) it is possible to infer[2] that the time-constant is about 20 msec. The fish is more sensitive to wide single pulses than to d.c.; this suggests that a sensory signal is initiated both by the beginning and the end of the pulse. Such an effect has been demonstrated electrophysiologically in gymnotids[8].

The sensitivity of *Clarias* to low-frequency pulse trains is shown in Fig. 3, and differs little from its sensitivity to the corresponding single pulses. Apparently the perception time is sufficiently short that the fish responds on the first pulse of the train; if adaptation is taking place, it must have a time-course rather longer than the perception time. With *Clarias*, therefore, information about adaptation is not available from experiments of the present type.

Gymnarchus niloticus, an electric fish possessing an exceedingly efficient object-locating mechanism, will respond to an electric field as low at 0·15 μV/cm. The sensitivity of *Clarias*, in which no continuous electric discharge has been found, is only a factor of five worse than this. What purpose, if any, does this remarkable sensitivity serve in the normal life of the fish? Perhaps, as has been suggested[3], the fish can detect action potentials from predators or prey. Alternatively it may locate nearby moving fish by detecting electric currents set up by the movement of water in the Earth's magnetic field[1,9]. It is, in any event, almost inconceivable that this great electrical sensitivity is fortuitous, and not used by the fish in any way.

Functional Polyovuly in the Sei Whale *Balaenoptera borealis* Lesson

On September 1, 1962, a female sei whale, 50 ft. long, was landed at Donkergat whaling station, Saldanha Bay, South Africa. It was found to be pregnant, with two fœtuses in the same cornu of the uterus but within separate fœtal membranes. There was only one corpus luteum of pregnancy in the ovaries so the twins were at first presumed to be monozygotic. However, of the two fœtuses, one proved to be male, 38 cm long, weighing 746 g, and the other female, 39·5 cm long, weighing 737 g (Fig. 1. Scale = 20 cm).

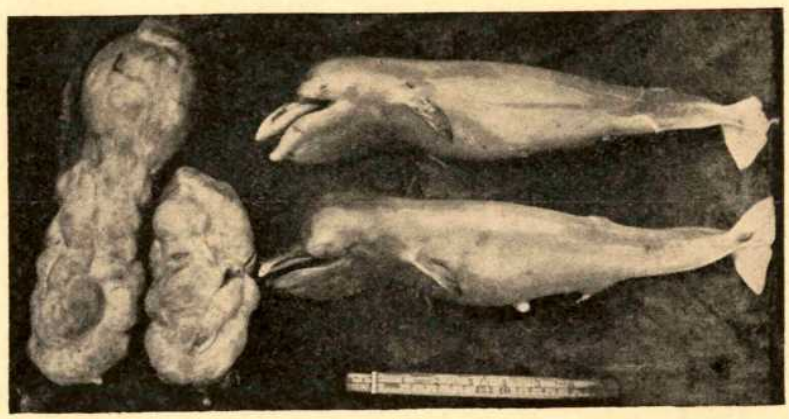

Fig. 1

When the ovaries were sectioned no evidence was found of any other recent luteal tissue representing a follicle from which a separate ovum could have originated. The only explanation therefore seems to be that the Graafian follicle concerned released at least two ova, and that fertilization occurred separately and almost simultaneously.

Polynuclear oocytes and polyovular follicles have been recorded from a number of animals, notably the opossum and dog[1], but they are usually thought to be most common in immature ovaries or among young follicles in a mature ovary. It seems that as the follicle approaches maturity the extra ova degenerate or the follicle becomes atretic, although Desaive[2] believes that in the adult rabbit, at least, resistance to atresia is greater in polyovular follicles than in monovular ones. Actual records of functional polyovuly in mammals are extremely rare. Corner[3] found in many hundreds of pregnant uteri of the sow only three or four examples where the number of embryos exceeded the number of corpora lutea, accounting for them by polyovuly and single-ovum twinning. In a sample of 2,179 rabbit litters, Allen, Brambell and Mills[4] calculated that only 0·23 per cent of the follicles ovulating could have been polyovular. On the other hand, Davis and Hall[5], who examined the ovaries of 394 wild Norway rats, suggested that the presence of polyovular follicles in at least 12 per cent of the animals could account for 20 out of 95 pregnant rats having more embryos in the uterus than corpora lutea in the ovaries.

Mackintosh and Wheeler[6] and Matsuura[7] both considered that whales might release more than one ovum at an ovulation, but Kimura[8] assumed that this possibility could be ignored. Up to the present time comparatively few sei whales have been examined by biologists, so that the significance of the present record cannot be appreciated until a larger sample has been examined. Kimura, however, showed that the sei whale seems to have a higher frequency of multiplets than any of the other large cetaceans.

We thank Saldanha Whaling, Ltd., for the provision of facilities at their whaling station.

Capillary Plexuses in Gastropods stained by the Novikoff Reaction for Thiamine Pyrophosphatase

The vascular system of molluscs is often spoken of as an 'open' one, wherein the exact relations of the arterial vessels to the venous system of vessels and lacunar spaces is as yet undetermined. The absence of an endothelium makes detection of the smallest vessels difficult and capillary plexuses as such have not been described in Gastropoda.

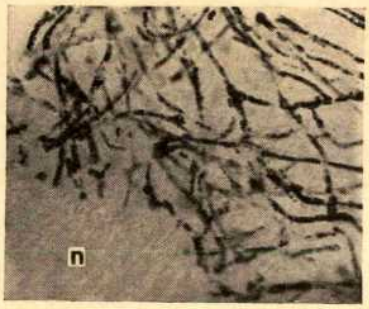

Fig. 1. Portion of the capsule of the pedal ganglion of *Helix*, containing numerous TPPase-positive granules contained within a delicate network of vessels. Neuropil *n* is TPPase-negative. Note that the plexus is coterminous with the capsule and the sharp line of demarcation with the neuropil. (× *c.* 800)

If the histochemical reaction of Novikoff *et al.*[1] for thiamine pyrophosphatase (TPPase) is applied to the pedal and cerebral ganglia of *Helix*, the periganglionic connective tissue gives a strong positive reaction. Large numbers of small darkly staining granules are seen to occupy the lumen of a system of delicate tubules which branch freely and anastomose with one another. The walls of the tubules consist of a delicate light brown coloured layer without nuclei. The appearance suggests a rich capillary plexus (Fig. 1).

Evidence supporting the concept that these vessels are in fact vascular capillaries was obtained by injecting the hæmocœle through the foot of the snail with carmine suspended in saline. The periganglionic tissue was then examined both in the fresh state and following fixation and staining with a variety of histological methods. Carmine particles were found within the tissue in positions corresponding to the TPPase positive particles; but the outlines of the vessels themselves always remained invisible.

The plexus is entirely limited to the periganglionic tissue. Vessels do not penetrate into the neural tissue (Fig. 1*n*), which in contrast is TPPase-negative. The borderline between capsule and ganglion is thus extremely sharp. Preparations impregnated by the reduced silver method of Cajal show that the capsular tissue is frequently pierced by nerve fibres, but these have a distinctive configuration and cannot be confused with the vessels revealed by the Novikoff reaction.

Why these vessels and their contained particles of TPPase-positive material should closely envelop the ganglia of *Helix* remains obscure. Their presence indicates a new significance for a tissue which has previously been regarded as merely a supporting capsule to the nervous elements of the ganglion.

Preliminary investigations have shown that similar plexuses are present in other snail organs, but they appear to be particularly well developed in the periganglionic tissues here described.

Cellular Uptake of Chloramphenicol as revealed by Fluorescence Microscopy

As a preliminary to investigations of the effects of chloramphenicol on mammalian cells in culture, some means of measuring intracellular uptake of the drug was sought. The fluorescence of tetracycline has been used to observe its localization within cells[1,2]; an investigation was undertaken to see if similar methods could be applied to the examination of chloramphenicol.

It was noted that solutions of chloramphenicol which were originally colourless and non-fluorescing became yellow during exposure to sunlight or when irradiated with an ultra-violet lamp. The coloured solution emitted a yellow fluorescence when irradiated with ultra-violet light in the dark and a precipitate formed after prolonged irradiation.

HeLa cells were grown as monolayers on cover-slips and then were exposed to solutions of chloramphenicol in saline or Eagle's medium for a few minutes. The cover-slips were mounted on slides without washing and examined with a dark-field fluorescence microscope (peak at 360 mμ). Cells mounted in a solution of 800 μg chloramphenicol/ml. showed an overall blue-white auto-fluorescence when first viewed; after 30–60 sec of irradiation this changed to a distinct specific yellow fluorescence within the cytoplasm and nucleoli. The intensity of this fluorescence increased with continued irradiation until a diffuse glow was [illegible] throughout the cytoplasm (Fig. 1). Eventually, cytoplasmic granules were apparent, the cells became swollen, and the cell membranes had a lacy appearance.

Fig. 1. Fluorescence microscopy of HeLa cells mounted in saline containing chloramphenicol (800 μg/ml.), photographed after 5-min exposure to the ultra-violet light of the microscope (× 600)

Cells mounted in saline or Eagle's medium without chloramphenicol initially showed the non-specific blue-white auto-fluorescence after exposure to the ultra-violet light, but this soon faded. No other type of fluorescence developed and in a short time it was difficult to see the cells. The intensity of specific fluorescence was proportional to the concentration of chloramphenicol and to the length of time that the cells were irradiated. A photomultiplier was attached to the microscope tube to measure the emission of light following the irradiation of chloramphenicol in individual cells. These measurements (Table 1) revealed a gradual increase in emission during 15 min of irradiation in the presence of chloramphenicol, but a gradual decrease in emission when cells were irradiated in saline alone.

In addition to HeLa cells, HEp. No. 1 cells, *L*-cells, and human embryonic fibroblasts were tested; these developed the same type of yellow fluorescence in the presence of chloramphenicol as did the HeLa cells. Specific fluorescence could also be demonstrated when cells in suspension were exposed to chloramphenicol.

Table 1. INCREASING EMISSION OF LIGHT DURING THE IRRADIATION OF INTRACELLULAR CHLORAMPHENICOL

Time (min)	Arbitrary units of light intensity: Chloramphenicol (800 μg/ml.)	Saline
0	150	91
0·5	180	
1	210	
1·5	230	70
2	245	
3	291	61
4	335	
5	462	62
7	560	
10	700	60
15	870	59

Cell viability was not required for the reaction since cells fixed in ethanol-acetic acid and cells killed by heat or irradiation showed characteristic fluorescence when exposed to chloramphenicol and irradiated. Although specific fluorescence appeared only in the cytoplasm and nucleoli, fixed cells in which ribonucleic acid had been degraded by ribonuclease (0·05 per cent for 30 min at 37° C) developed fluorescence in these same areas when irradiated afterwards in the presence of chloramphenicol.

When cells were exposed to solutions of chloramphenicol and then washed at 4° C so that the concentration of chloramphenicol in the surrounding medium was reduced from 800 μg/ml. to less than 1 μg/ml., enough intracellular chloramphenicol was retained to produce fluorescence as intense as in unwashed cells. However, if washing was carried out at 25° C, intracellular chloramphenicol was removed and no fluorescence developed during subsequent irradiation.

Chloramphenicol itself is not fluorescent but when solutions of chloramphenicol are degraded by exposure to ultra-violet light one or more of the products formed has this property; fluorescence microscopy of these products can be used to demonstrate cellular uptake of the chloramphenicol. Cells which contain chloramphenicol become increasingly fluorescent because more fluorescent compound is being formed. Intracellular concentration or binding of chloramphenicol or its degradation products is needed for visible fluorescence since little or no fluorescence is seen in the background. The actual amount of intracellular chloramphenicol which must be present has not been determined so that the technique is, as yet, only semi-quantitative. It does, however, demonstrate that chloramphenicol enters cells in culture and is reversibly bound to a non-ribonucleic acid receptor. That this receptor is protein is suggested by the observation of Felsenheld and Carter[3] that chloramphenicol binds non-specifically with protein.

This work was supported in part by grant C–1355 of the U.S. Public Health Service.

Effects of Magnetic Fields on Tomato Ripening

ACCORDING to Duclaux[1], Pasteur explored the possibility of the effect of a magnetic field on the production of optical isomers of tartaric acid. He theorized that the Earth's magnetic field caused tartaric acid to be of one optical isomer in nature, whereas laboratory synthesis produced a mixture of both isomers. Recently, Krylov and Tarakonova[2] proposed an auxin-like effect of a magnetic field on germinating seeds. They called this effect magnetotropism. Auxins or synthetic plant growth regulators have been used to stimulate ripening of immature fruits[3].

Investigations were conducted here to determine the effect of a magnetic field on the ripening of green tomatoes (*Lycopersicon esculentum* Mill. var. V. R. Moscow). Four permanent magnets of considerable strength were utilized. Fruits of uniform maturity were placed between the magnetic poles. The experiment was conducted in a ripening chamber at 21° C and 85 per cent relative humidity under dark conditions. The ripening rates of treated fruits were compared with those of untreated controls in the same room under similar conditions. A numerical value for colour (1 = green, 2 = breakers—just starting to colour, 3 = pink, and 4 = red) was assigned for each fruit in a given sample at each observation period. The coefficient of ripening was calculated as follows:

$$\text{Ripening coefficient} = \frac{\text{total score for a sample}}{\text{No. of fruits in the sample}}$$

In all cases the treated fruits ripened faster than the controls (Fig. 1). Furthermore, the fruits nearest the magnetic south ripened faster than those nearest the magnetic north.

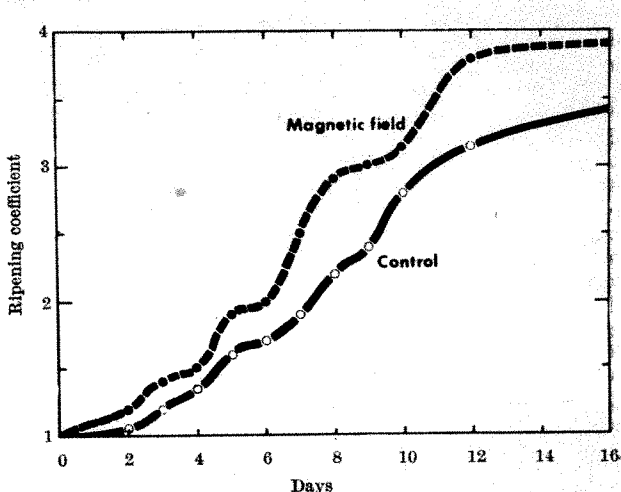

Fig. 1. Effect of magnetic fields on ripening of tomatoes (V. R. Moscow variety)

To expand this experiment further, cherry type (*Lycopersicon esculentum* Mill. Breeding lot No. 1064) tomato fruits of uniform mature-green maturity were used. The small size of these fruits made it possible to increase the number of fruit in each replication. In all cases the treated tomatoes ripened faster than the controls. The polarity effect resembled that noted in the exploratory experiment.

Speculations as to mechanisms associated with this phenomenon could be as follows: (1) an auxin-like character of the magnetic field, as proposed by Krylov and Tarakonova[2], or perhaps an auxin-activating mechanism speeds the ripening process; (2) activation and/or acceleration of the enzyme systems could enhance respiration; (3) radical formation could speed up respiration and thus accelerate ripening.

The possibility that fruit ripening is initiated by a hormone is well known. The experiments carried out by Krylov and Tarakonova[2] demonstrate the similarity of the magnetic effect and effects of plant growth regulators. Pauling and Coryell[4] have shown the magnetic characteristics of the iron porphyrin compounds. The cytochrome oxidase system, which belongs to this group of compounds,

could be functionally influenced by a magnetic field. Smith and Cook[5] have reported on the effect of magnetic field on trypsin activity. The formation of radicals is a common step in organic reactions. It is possible that a magnetic field could promote the loss or gain of protons and/or other reactive groups from compounds in the respiratory cycle.

We thank Prof. J. O. Jensen, of the Physics Department, for furnishing us with the magnets used in this work.

Oil Spot Disease in Tea

Mulder and Shanmuganathan[1] first reported in 1959 a disease of tea referred to as 'oil-spot of tea leaves'; but they failed to ascribe any definite cause for it. From further investigations carried out here, we have now obtained evidence that the causal organism of this disease is a fungus.

The cause of the disease has for a long time remained obscure as all efforts to isolate a pathogen from the diseased shoots have proved unsuccessful, and attempts to transmit the disease by grafting and sap inoculations have also failed. A fungus has now been identified as the cause of this complex of symptoms. This organism is a weak parasite which remains for the most part in the basal portions of the tea bush, being confined mainly to the wood of the frame. When the main branch below the diseased part of a bush is cut a sector of the wood often appears discoloured, and it has been possible to isolate the pathogen from this area. The same fungus has been isolated from diseased bushes collected from several estates, and experiments indicate that it produces a toxin which acts at a distance from the site of infection, and gradually destroys the entire plant.

The fungus was grown on a modified Czapek–Dox medium containing 10–15 per cent dextrose or sucrose for 3 weeks at room temperatrue (23° C). At the end of this period, it had formed a thick mat, and the liquid was removed by filtration and rooted cuttings of tea (clone *TRI* 2049) were placed in the filtrate. Characteristic oil-spots and necrosis of the veins, typical of the disease, occurred after 4 days (Fig. 1). Cuttings placed in the original pure liquid culture remained free from symptoms. Young bean plants produced water-soaked spots on the leaves and browning of the vascular tissues when placed in the same culture filtrate, and excised tomato shoots showed rapid wilting followed by necrosis of the leaves.

Attempts were also made to extract the toxin from diseased plant material. Diseased wood was comminuted thoroughly, extracted with distilled water, and rooted cuttings were placed in the filtrate. Typical oil-spots appeared after 4–5 days; extracts from healthy wood were non-toxic.

The lesions produced by the culture filtrates are so characteristic that there can be little doubt that the toxin produced by the fungus in the host plant is the same substance as that found in the culture filtrates.

The fungus has so far remained sterile on several media, and has thus defied all attempts to identify it.

Stimulation by Citric Acid of Germination of Eastern Red Cedar (*Juniperis virginiana* L.)

I have found that pretreatment with citric acid increases both speed and total germination of eastern red cedar seed. Earlier, exploratory investigations showed that the acid also increased both speed and total germination of bald cypress seed (*Taxodium distichum* (L.) Rich) and I have reported similar effects of pretreatment of eastern white pine seed (*Pinus strobus* L.) with both citric and tartaric acids[1]. Of the several species examined, eastern red cedar showed the most striking response to pretreatment with citric acid.

A fresh lot of eastern red cedar cones was soaked in water and all pulpy material removed by hand using screens and sedimentation. The cleaned seeds were allowed to dry in air for 3 days at room temperature and then given one treatment in a factorially designed study involving 6 chemical treatments, 5 soaking periods, 4 stratification periods, and 2 stratification temperatures.

Three 100-seed samples were drawn from each treatment combination and germinated on a sand–vermiculite medium in the dark at a constant temperature of 14° C. Germination percentage was expressed as that of full seed (about 90 per cent for this work) and were tallied when the radical penetrated the medium and lifted the seed coat completely. I was primarily concerned with germination percentages occurring within 30 days because maximum germination with maximum speed is desirable.

Fig. 1 shows results for some of the better treatments. When seeds were soaked for 4 days in a 10,000 p.p.m. solution of citric acid, prior to 90-day stratification, there was 93 per cent germination at 30 days. A 4-day soak in water with 90-day stratification gave 73 per cent germination and stratification alone gave only 23 per cent germination. For the 90-day stratification period, seed soaked in citric acid and in water showed an increase in 30-day germination of 304 per cent and 217 per cent, respectively over no soaking. Seed receiving no treatments did not begin germination until 70 days and reached only 43 per cent at 120 days.

The main factor in inhibition of germination in eastern red cedar is embryo dormancy[2-4]. Its embryos exhibit both primary and secondary dormancy[2,4]; but because these were fresh seed, secondary dormancy may not be a factor. Whether citric acid creates the same response with secondary dormancy has not been determined.

The nature of the embryo dormancy of this species, therefore remains the important question. It is known that water will sometimes remove inhibitors from seed. The seed coats of eastern red cedar are impermeable to water, but

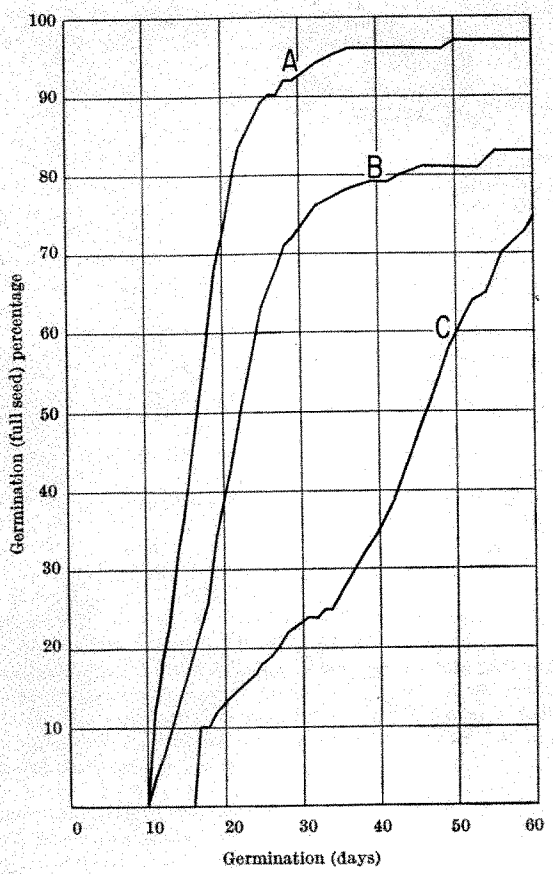

Fig. 1. Germination of eastern red cedar seed after 90-day stratification at 3° C with a prior treatment of: *A*, 4 days' soaking in a solution of 10,000 p.p.m. citric acid; *B*, 4 days' soaking in water; *C*, no treatment

can be made permeable by moist storage for 8 weeks at 25° C prior to stratification[3]. It has been shown that the dormant eastern red cedar embryo has an alkaline *p*H, but a germinating embryo has an acid *p*H (ref. 4). If this is so, What part does citric acid play? Is it one of increasing the efficiency of water as an extractant, the activation of the Krebs cycle, the production of an acid environment necessary for embryo metabolism, or is it a combination of these possibilities?

Other experiments to elucidate further the role of citric acid and similar compounds are being carried out. The response of eastern red cedar seed to a pretreatment of citric acid does not appear to be an isolated instance, as investigations now being carried out with seeds of *Pinus taeda* L., *P. strobus* L., *P. echinata* Mill., and *Taxodium distichum* (L.) Rich show that these seeds have a similar reaction to a citric acid pretreatment. Citric acid does not produce the same effect on all seed; Evanari[5] reported an inhibitory effect of this compound on some seed.

I thank Dr. A. A. Foster, of the Tennessee Valley Authority, for supplying eastern red cedar cones. This work was supported by the Georgia Forestry Commission, the Georgia Forest Research Council and the Eastern Tree Seed Laboratory.

A Nutrient Requirement for Optimum Water Absorption by Intact Root Systems

Eaton[1] found that a tomato plant with half its root system in distilled water and the other half in nutrient solution, after an initial period of three days, absorbed more water from the nutrient solution than from the pure water. He attributed this difference to reduced root growth in distilled water. However, it has been shown that an inadequate external solute supply can lower the osmotic pressure of the xylem sap[2], and it has been postulated that the metabolism and permeability of the roots may be affected by the concentration of the external solution[3]. Part of the difference in water absorption from distilled water and nutrient solution might be caused by such effects, and this has been demonstrated during the course of experiments at this Station on the relationship between water absorption and the concentration of the external solution.

Seeds of *Zea mays* L., variety North Star, were germinated in sand and 18-day-old seedlings placed singly in jars containing 2·4 l. nutrient solution (Long Ashton solution[4], with the $NaH_2PO_4.2H_2O$ partly replaced by K_2HPO_4 to raise the *p*H). The seedlings were supported by cotton wool in small holes in the corks closing the jars. After three weeks this solution was replaced by other concentrations of the Long Ashton solution, which had osmotic pressures from zero (rain-water) to three atmospheres. There were seven replicates of each treatment. The cultures were not aerated.

Water absorption was measured every 24 h by adding demineralized water from a burette until the original level of solution in the jar was restored. The results are shown in Fig. 1. The only marked difference observed at the end of the first 24-h period was a reduction in the amount of water absorbed from the 3-atmosphere solution. During the second 24-h period there was a considerable reduction in water absorption from the rain-water. It seems unlikely that within 48 h a sufficient reduction in root growth could occur to account for the observed depression of water absorption. Plant weights were not determined at this stage, since the effects of continuing

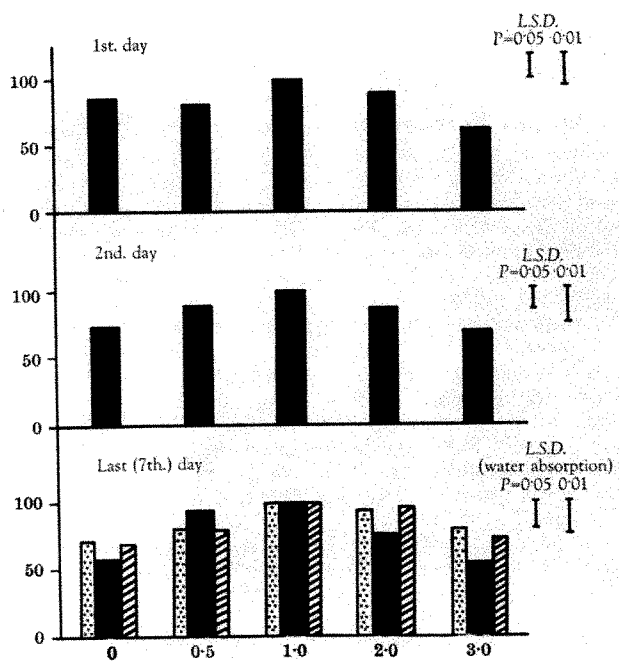

Fig. 1. Effect of concentration of the nutrient solution on water absorption and root and shoot growth of *Zea mays* L. Black, relative water absorption; stippled, relative fresh weight of roots; hatched, relative fresh weight of shoots

the treatments were being investigated. However, as can be seen from the bottom set of histograms in Fig. 1, on the seventh day the pattern of differences in fresh weights, not only of the roots but also of the shoots, was roughly similar to the pattern for water absorption.

The relationship between water absorption and root and shoot weights was clarified by calculating the regression coefficients. It was assumed that the relationships would be linear and that, when root or shoot size was zero, water absorption was also zero. The values (Table 1) show that there was a significantly lower volume of water absorbed per unit weight of root or shoot from the rain-water than from the 0·5-atmosphere solution. A similar result was obtained with *Triticum aestivum* L., variety Jufy 1, where the optimum nutrient solution had an osmotic pressure of 0·1 atmosphere.

Table 1. Effect of the Concentration of the Nutrient Solution on the Amount of Water Absorbed in 24 h per unit Fresh Weight of Root and Shoot of *Zea mays* L.

Osmotic pressure of nutrient solution (atm.)	Coefficient of regression of water absorption on: Fresh weight of roots	Fresh weight of shoots
0	1·38 ± 0·124	0·59 ± 0·052
0·5	2·03 ± 0·177	0·85 ± 0·058
1·0	1·71 ± 0·044	0·70 ± 0·034
2·0	1·38 ± 0·049	0·57 ± 0·014
3·0	1·19 ± 0·051	0·52 ± 0·018

It was concluded, therefore, that the maximum rate of water absorption by intact root systems was only achieved in the presence of nutrient ions in the external solution and that the ions affected the ability of the roots to absorb water, in addition to affecting the size of the absorbing and transpiring organs. This conclusion is supported by the results of other experiments of a different type and a full account of the methods and results is being prepared for publication elsewhere.

ENTOMOLOGY

Queen Perception by Honey Bee Swarms

Should a honey bee (*Apis mellifera*) swarm emerge without a queen or its queen be unable to fly, the swarm soon returns to the parent colony. When the queen is taken from a swarm soon after it has settled, the bees usually become disturbed within 10–15 min[1] and soon return to the old hive. Colonies deprived of hives and combs behave like swarms[2], and were used in the present experiments. When such a colony was allowed to cluster on a branch clamped in a retort stand and its queen was taken away, the worker bees soon became restless, running about on the surface of the cluster, flying off and returning, apparently searching the immediate neighbourhood for the queen. The disturbance increased until most of the bees were taking part in it, and eventually, unless the queen was put back, all the bees (except those too young to fly) joined other colonies.

A queen in a wire screen cage stabilized the cluster, even when the cage had double walls separated by a gap across which bees could not reach. When a queen in a double-walled cage was suspended about 20 cm from a queenless cluster which had reached the disturbed stage, the worker bees that landed on the cage immediately started running agitatedly over the wire screen, vibrating their partially spread wings. Some tried to get their heads between the wires of the screen and extended their tongues towards the queen. When the queen was put in a single-walled cage, the workers tried to lick her body though usually they could not reach it; they could easily have licked her feet but were not seen to do so. With either type of cage other bees appeared to be attracted to those already there, so that the number on the cage quickly increased. Few bees were seen with their abdominal (Nassanoff) scent glands open except when the cluster of bees building up on the cage touched the queenless cluster; when this happened, bees started streaming towards the cluster with the caged queen, opening their Nassanoff glands and fanning air backwards with fully spread wings. The whole queenless cluster then soon joined that with the queen. A double-walled cage that had contained a queen stabilized the cluster for more than 12 h. The worker bees attracted to the cage congregated on the wire screening and not around the plugged hole in the wooden part through which the queen had been removed. A queen in a cage in a thin polythene bag, through which sounds she produced could be heard, did not stabilize the cluster, and the worker bees did not seem to perceive her in any way. Evidently it is the scent of a queen that stabilizes a swarm.

To investigate the origin of this scent the freshly severed head, thorax and abdomen of a laying queen were put into clean new queen mailing cages, kept with their wire screening uppermost so that bees could not touch their contents, and hung simultaneously about 20 cm from a dequeened 'swarm'. Little evidence of attractiveness was seen when the parts of the queen were whole, but there was much after they were crushed; bees that landed on the cage containing the crushed head remained on it, vibrating their wings and trying to get through the wire screen, whereas they were not attracted by the cages containing the crushed thorax and abdomen. All three cages were then held in the queenless cluster until they became covered with bees, when they were withdrawn and suspended about 20 cm away. The bees on the cage with the head remained there, showing interest in its contents; but those on the other two cages soon flew off. Within 1·5 h all the bees of the colony were on the cage with the head. The corresponding parts of a virgin queen about 3–6 days old gave similar results. The stabilizing scent was therefore mainly in the queens' heads, presumably in the mandibular glands, removal of which greatly diminishes a queen's power to attract workers in a hive[3]. Pure 9-oxodec-*trans*-2-enoic acid, the principal component of queens' mandibular gland secretion[4], presented on filter paper in a cage, did not stabilize a 'swarm', and the workers showed no response of any kind to it, even when they were allowed to touch the paper. This substance is unattractive to young worker bees[5], and queenless bees in an arena do not cluster more readily on a cage containing it than on an empty cage[6]. Evidently some other component of the secretion is responsible for its attractiveness. The unattractiveness of an intact dead queen compared with a living queen or a cage that had contained one suggests that a living queen discharges the secretion frequently and contaminates her surroundings with it.

A 'swarm' that had been left as an exposed cluster with its queen in a cage for several days suddenly dispersed and immediately flew about 120 m in a straight line, presumably towards a chosen nest site[7], halted, hovered for a time, and finally returned to the caged queen. Apparently swarming worker bees, even while flying, can detect whether or not they are accompanied by their queen. If they do this by smelling, she presumably must fly in front of the swarm. As she has not previously visited the new nest place she is unlikely to be leading the swarm to it, but she may perhaps be driven from behind. When a swarm is leaving a hive the queen appears to be driven out by the workers, which stop moving forward whenever the queen does, so that the bees coming behind pack together and prevent her from running back[8]. Possibly a travelling swarm behaves similarly with workers falling back to get behind the queen whenever they do not smell

duct is bound up near the liver. Further, about 3 cm from the duodenum, a soft rubber tube of appropriate thickness is inserted into the bile duct and fixed. The other end of the tube, provided with the silon net to prevent blocking of the tube with the killed worms, is inserted into the gall bladder. So the flow of bile is in no way interfered with, and no flukes are lost after being killed by the substance under trial. Using this method new anthelmintics have been examined on 75 sheep and the work continues.

The operation is performed in 'Thiopental^{R}' anæsthesia and usually lasts for about 35–45 min. Some hours later the anthelmintic is given. The animals are killed on the fourth or fifth day. By thorough helminthological dissection of livers the mature flukes are picked up and ascertained to what extent they became necrotic. In this way a direct comparison is made, and the percentage of worms killed or damaged is assessed exactly. By this method the action against immature stages of liver flukes could be examined, too. Apart from this the method is suitable for testing substances against *Dicrocoelium lanceolatum*.

Most of the animals lived after the operation as needed, but in the early stages of the work some animals succumbed before the fourth day. Some of the animals which were not killed lived for 3–6 months and one is still alive after more than a year.

The examination of some known anthelmintics (1,4-*bis*-trichlormethylbenzene, hexachlorophene, 'Freon 112') has shown that the method works well and enables one to perform critical test with substances acting against *Fasciola hepatica* in sheep.

Resuscitation of Sheep Embryos and the Simulation of Intra-uterine Life

Preliminary investigations made on the short-term revival of embryos obtained from sheep at slaughter suggest that extra-uterine maintenance of mammalian embryos is a technique awaiting development and exploitation.

Embryonic sheep between 5 and 33 cm CR-length (43–113 days[1]; gestation period, approximately 150 days) were connected to a simply-constructed heart-lung machine with the roller-pump in series with the embryonic heart. An artificial amnion made of 'Perspex' was filled with 0·9 per cent sodium chloride at 39° C and through the wall of this tank entered two rubber-tubes which served as extensions for the umbilical vessels. Each tube was convoluted within the saline and then passed through the liquid surface to the operating table. The cannulæ used for connecting these tubes to a fœtus were transparent polyvinyl chloride or polythene ('Portex'). The output tubing from the pump passed to the tank and connected with the umbilical vein extension; the umbilical artery extension was taken from the tank to an oxygenator of the rotary-disk type[2,3]. Heparinized Ringer solution and acid-citrate dextrose (ACD) were used as blood substitutes. Oxygen was metered into the disk-chamber in a direction opposing the flow of the liquid; after passing the disks the liquid was recirculated by the pump.

Before an experiment the oxygenator was charged with either solution and the cannulæ mutually connected with plastic tubing. The pump was switched on and the liquid drawn from the oxygenator was passed down the umbilical vein extension through the joined cannulæ to the umbilical artery-extension and returned to the oxygenator. The pump was stopped and the cannulæ were disconnected at the operating-table level. Since this table was lower than the oxygenator there was now gravity-feed from the artery extension and this temporarily reversed flow was necessary for the insertion of that cannula. This flow was controlled by a clip and the flow from the vein extension by switching the pump.

Pregnant uteruses from the Bristol Public Abattoir were sealed in polythene bags and plunged into water at about 39° C. They were brought to the laboratory as quickly as possible, but the interval between killing the ewe and the dissection of its uterus was never less than 18 min.

A large cut was made through the uterine wall and fœtal membrane of a conceptus, the incision running between and parallel to lines of cotyledons. As the fœtus was lifted from the amniotic fluid and placed on sponge-rubber its cord was unravelled and gently stretched. An umbilical vein was entered after placing a linen-thread ready to ligate it; the pump was switched on and the stream of liquid from the cannula used to wash the site at which the vein was opened. When the vein was cannulated the pump was stopped until an artery was similarly connected, then the remaining umbilical vessels were clamped and the cord sectioned on the placental side of the connexions. The fœtus was raised to just above the level of the meniscus in the oxygenator and the heart-pump switched on. If the pumping and connexions were satisfactory, the fœtus, accompanied by cannulæ and vessel extensions, was lowered into the amnioid cavity.

Six mechanically successful transfers were effected; 3 using ACD and 3 using heparinized Ringer. In all cases serious œdema developed within 15–20 min and the embryos, still connected, were taken from the saline for examination. In those receiving ACD and in one receiving Ringer no activity was observed on exposing the heart, but in the remaining two Ringer cases strong rhythmic activity was present with ventricular as well as atrial contraction. Since, apart from several temperature measurements, the biophysical system was unmonitored and the technique empirical it was expected that unphysiological conditions would be rapidly established. Neither perfusion fluid used could be expected to sustain the embryos for long and the use of whole blood should give better results.

I thank Miss J. Honour, who helped to construct the plastic parts of the apparatus, and Mr. T. Baker, who collected the biological material.

SOIL SCIENCE

Occurrence of a Previously Unobserved Nitrogen Gas in the Reaction Product of Nitrous Acid and Lignin

During investigations into the nature of gases produced by the reaction of nitrous acid with soil humic acids and lignins, a product was obtained from lignin which showed anomalous behaviour. There was a slow uptake of gas by permanganate solution beyond the time required for

complete adsorption of nitric oxide (formed by self-degradation of nitrous acid during the reaction). For example, with the products obtained from humic acids, there was no further uptake of gas beyond a 10-min period of contact with permanganate; with the product obtained from lignins, some gas was still being adsorbed after an 8-h period. This result suggested that the gases from lignins contained a compound which was not present in the gases recovered from humic acids. To explore this possibility, infra-red analyses were made of the gaseous products obtained by reacting nitrous acid with humic acids, lignins and some lignin-building units.

The gases were prepared for analysis by reacting a 50- to 200-mg sample of the substance in question with nitrous acid in a Van Slyke manometric apparatus, using a technique similar to that utilized for the determination of amino nitrogen by the nitrous acid method[1]. The procedure was similar to that Bremner[2] described for the reaction of nitrous acid with humic acids and lignins, with three exceptions: (1) the reaction was carried out in a dilute sulphuric acid solution instead of an acetic acid solution; (2) a Na_2HPO_4–$KMnO_4$ mixture, rather than a NaOH–$KMnO_4$ solution, was used to remove nitric oxide; (3) adsorption of nitric oxide was carried out in the reaction chamber of the manometric apparatus. Preliminary trials showed that adsorption of nitric oxide was complete within 10 min; nevertheless, the sample was allowed to remain in contact with the permanganate solution for 20–30 min before the infra-red analysis was performed.

Typical infra-red absorption patterns of the gases obtained by reacting nitrous acid with a soil humic acid and with some phenolic compounds are reproduced in Fig. 1. In every case the infra-red patterns showed only the presence of nitrous oxide[3]. In general, 0·25–0·5 of the gases consisted of nitrous oxide; the remainder was elemental nitrogen.

The infra-red patterns of the gases obtained from lignins, syringic aldehyde, and syringic acid are reproduced in Fig. 2. In these cases, absorption bands were obtained which did not correspond to nitrous oxide (Fig. 1), or to nitric oxide, nitrogen dioxide, nitrogen

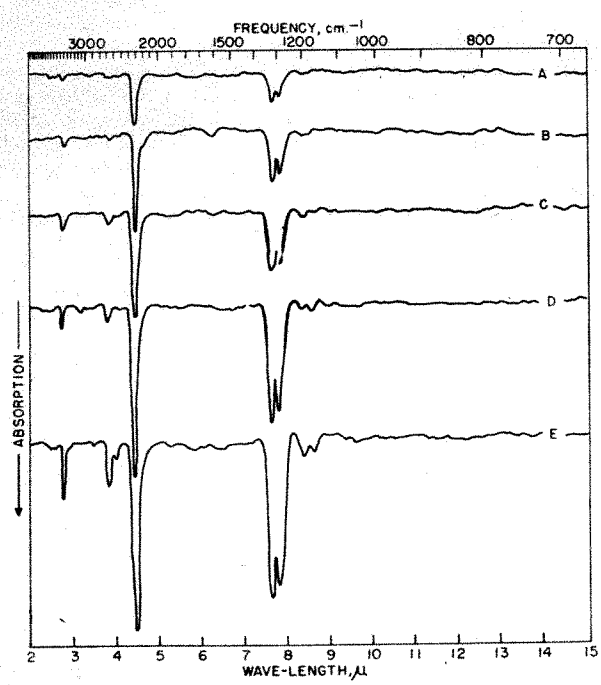

Fig. 1. Infra-red absorption spectra of gases from nitrous acid treatment of: (*A*) humic acid, 200 mg; (*B*) pyrogallol, 50 mg; (*C*) protocatechuic acid, 50 mg; (*D*) catechol, 50 mg; and (*E*) phloroglucinol, 50 mg. Nitric oxide had previously been removed by adsorption in permanganate solution

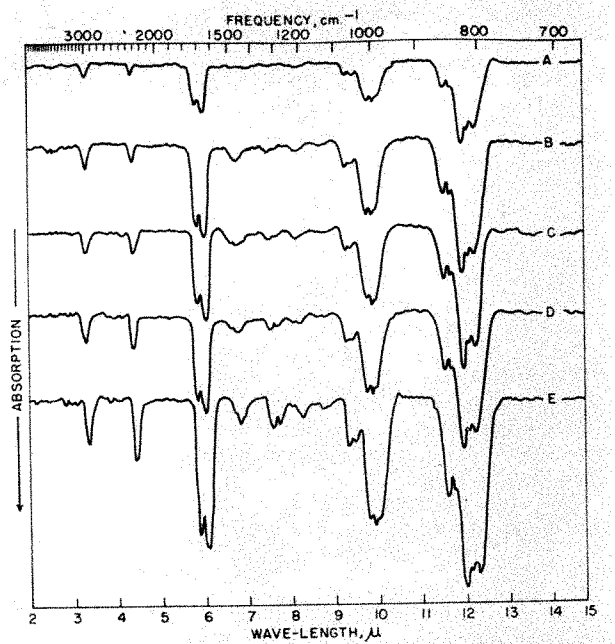

Fig. 2. Infra-red absorption spectra of gases from nitrous acid treatment of: (*A*) 'Meadol MWS' lignin, 50 mg; (*B*) methanol lignin, 100 mg; (*C*) syringic acid, 50 mg; (*D*) syringic aldehyde, 50 mg; and (*E*) 'Meadol MWS' lignin, 100 mg. Nitric oxide had previously been removed by adsorption in permanganate solution

peroxide, dinitrogen tetraoxide, nitrogen pentoxide nitromethane, hydrogen nitrate, hydrazine, ammonia hydrogen cyanide, methyl azide, cyanogen or diazo methane[3]. No report of an infra-red pattern whicl corresponded to that of the unknown was found in th scientific literature.

Other experiments showed that only compounds con taining the syringyl group produced the unknown gas indicating that this group is the structural unit in lignin responsible for the formation of the gas.

Whereas the amount of the unknown gas recovere from the gaseous mixture decreased with increasin periods of contact with permanganate solution, there wa an increase in the quantity of nitrous oxide recovered This result suggested that the unknown gas containe nitrogen. This supposition was confirmed in experiment in which sulphite was used to reduce the gas; the un known gas was completely adsorbed by aqueous sulphit and acidification of the resulting mixture resulted in th production of considerable quantities of nitrous oxide, a revealed by infra-red analysis. The unknown gas ha the properties of a polymerized nitric oxide.

Controlled experiments showed that the unknown ga was not an artefact arising from any of the reagents use for analysis, neither was it a product synthesized durin the removal of nitric oxide by permanganate. It i concluded that the gas is a true product of the reactio of nitrous acid with lignin.

PSYCHOLOGY

Sources of Difficulty in Learning Arithmetical Facts

SEVERAL investigations have been carried out on the relative difficulties of learning the various 'arithmetical facts' or tautologies contained in the multiplication and addition tables. A variety of operational criteria of 'difficulty' have been used by different workers, one of whom[1] gives a comparative review of earlier work, with which his own results substantially agree. In particular it seems clear that the chief source of difficulty with a given combination (such as $2.7=14$ or $4+5=9$) is the size of the numbers concerned. However, on the question of which numbers, exactly, are responsible for the difficulty—the addends and factors, or the sums and products—both the evidence and the considered opinions of different investigators are nicely balanced between the two points of view.

In the case of addition, Knight and Behrens[2] concluded that the size of the sum determined the difficulty, defining the latter in terms of learning, mistakes and calculation-time. Yet they suspected that the size of the addends influenced the way in which the relative difficulties fell into groups. Wheeler[1] found similar results, but favoured the size of the addends as the primary source of difficulty. In Wheeler's experiment, after some preliminary teaching 125 children practised addition by playing an educational card-game for a fixed period each day. The different additive combinations were then ranked in order of increasing difficulty, according to the proportion of children answering correctly in a written test on the 20th day. Wheeler found correlation coefficients of 0·87 and 0·95 respectively, between difficulty-rank and size of sum, and difficulty-rank and size of addends. Since the combinations were differently grouped for the two tests it can only be inferred that 'difficulty' is closely related to both variables.

In the case of multiplication, opinion is still more narrowly divided. Wheeler[1] cites two investigations in which the size of the product, and three in which the size of the factors, were judged to be the primary source of difficulty. He himself, using a second educational card-game, found almost identical correlations; for the product, $r=0{\cdot}92$, for the factors, $r=0{\cdot}94$.

Much of the ambiguity throughout clearly stems from the fact that for both additive and multiplicative combinations (generally expressible in the forms $x_1+x_2=x_3$ and $x_1.x_2=x_3$ respectively) x_3 is heavily dependent on x_1 and x_2 by definition. Consequently the two hypotheses, linking difficulty with x_3 on one hand or with a joint measure of (x_1, x_2) on the other, are to a large extent confounded and statistically indistinguishable. Even if only for this reason, a new unifying hypothesis involving x_1, x_2 and x_3 in combination, which made it unnecessary to choose between these two alternatives by giving at least equally high correlations, would be preferable to either of them.

Some recent work on timed calculations by adults, including simple one-stage additions and multiplications of the type considered here, suggests a formula which may be the appropriate collective measure of 'calculation-size' or 'complexity' for use in the present dilemma[3]. In some circumstances at least, the average time taken to perform a simple one-stage arithmetical operation R on a pair of one-digit numbers (x_1, x_2) to give a result x_3 is strictly proportional to $\log(x_1+x_2+x_3)$. Thus for multiplications, $x_3=x_1.x_2$; for additions, $x_3=x_1+x_2$ and $\log(x_1+x_2+x_3)=\log 2(x_1+x_2)$. The correlations between 'difficulty' and the appropriate values of $\log(x_1+x_2+x_3)$, according to Wheeler's data, have therefore been examined and compared with correlations obtained on the hypothesis that either (x_1, x_2) or x_3 alone is responsible for the difficulty.

The first test was applied to the ungrouped data on multiplications. 'Double' combinations for which $x_1=x_2$ were excluded and, apart from these, a combination and its reverse were treated as distinct. All combinations with 0 or 1 as a factor were excluded. The remaining combinations were then ranked according to the percentage of children performing each one correctly in the final test. For these 64 combinations, ungrouped, the correlation coefficients (with respect to difficulty-rank number in each case) are as follows: *Product*, $(x_1.x_2)$: $r=0{\cdot}79$; *mean factor-size*, $\frac{1}{2}(x_1+x_2)$: $r=0{\cdot}80$; and for $\log(x_1+x_2+x_1.x_2)$: $r=0{\cdot}84$.

In the second test the multiplicative combinations were classed into 18 groups in the manner adopted by Wheeler, including 0 and 1 as factors but excluding 'doubles'; in each group either x_1 or x_2 is held constant. For each combination, $\frac{1}{2}(x_1+x_2)$, $(x_1.x_2)$ and $\log(x_1+x_2+x_1.x_2)$ were separately computed and the difficulty-rank taken from Wheeler's complete list. Correlations were computed for the group arithmetic means of these quantities. Correlation coefficients with respect to difficulty-rank are: *Mean product:* $r=0{\cdot}88$; *mean factor-size:* $r=0{\cdot}93$; *mean* $\log(x_1+x_2+x_1.x_2)$: $r=0{\cdot}95$.

Applying the second test to Wheeler's data for additions, excluding 0 as addend and excluding 'doubles', grouping and averaging as before, the correlations are: *Mean sum:* $r=0{\cdot}97$ (mean addend would give the same r); *Mean* $\log 2(x_1+x_2)$: $r=0{\cdot}99$.

In every case, therefore, difficulty-rank correlates at least as well with $\log(x_1+x_2+x_3)$ as with the arithmetic mean of (x_1, x_2) or with x_3.

As already observed, the argument in favour of $\log(x_1+x_2+x_3)$ as the pertinent psychophysical variable only requires this condition to be satisfied; the value of the present hypothesis is, primarily, that it removes the need to decide between two statistically indistinguishable hypotheses, each of which only takes one part of the calculation into account. However, the hypothesis gains indirect support from the fact that, unlike x_3 or $\frac{1}{2}(x_1+x_2)$, the function $\log(x_1+x_2+x_3)$—under suitable conditions—is strictly proportional to the time taken by adults to perform the corresponding calculation. It may be noted that although Wheeler ranked additions purely by 'learning-difficulty', whereas Knight and Behrens used calculation-time as one of their criteria of difficulty, the two rankings agree closely ($r=0{\cdot}91$), a fact which again suggests that one and the same measure of calculation 'size' may be a major factor in both learning-difficulty and, subsequently, calculation-time.

This work was supported by a Mental Health Research Fund fellowship and I thank Dr. W. E. Hick of this laboratory for his criticism and advice.

Influence of Stroboscopic Illumination on the After-effect of Seen Movement

THE after-effect of seen movement (sometimes known as the waterfall effect) is a well-known illusion in which steady viewing of a moving patterned surface is followed, on transfer of one's gaze to a stationary surface, by an apparent motion in the opposite direction. Pickersgill[1] gives an exhaustive review of the literature.

We have recently investigated the effect of lighting the stationary surface stroboscopically instead of constantly. The stimulus pattern first used (by R. L. G. and S. M. A.) was a rotating Archimedes's spiral which is seen as expand-

ing or contracting, the opposite apparent motion being normally visible as an after-effect. The after-effect was viewed against a similar, stationary spiral. It was found that stroboscopic illumination of the stationary surface abolished the after-effect. If the stationary spiral is seen by dim steady illumination, the stroboscopic flashes being introduced from the same visual direction via a half-silvered mirror without illuminating the spiral, then the after-effect is not abolished.

If the stationary spiral is illuminated with both steady and stroboscopic light, the after-effect may be made just apparent with a critical balance of their intensities. The after-effect disappears when the stroboscopic illumination is just intense enough to cause apparent instability of the stationary spiral.

In later experiments (by D. M. M. and N. de M. R.) the stimulus was a rotating circular granular black-and-white pattern. In this case, the after-effect of movement was not abolished by stroboscopic illumination of the stationary granular field, but it was briefer than with constant illumination, for flash rates of 4–30/sec. A rotating Archimedes's spiral containing more turns than that used by R. L. G. and S. M. A. and producing a subjectively stronger after-effect, gave results like those obtained with the granular stimulus, except that the after-effect was more readily suppressed by the lowest flash rates (4–10 flashes/sec).

These findings may have a bearing on the insensitivity to real motion observed in stroboscopic illumination[2]. It now looks as if intermittent illumination of a moving contour not only removes motion-information from the input to the postulated velocity-abstracting system, but also may (at least partially) inhibit its action.

ANTHROPOLOGY

Frequency of Spina Bifida Occulta in Prehistoric Human Skeletons

In a cave at Taforalt, in the Beni Znassen country of north-eastern Morocco not far from Oujda, the Abbé J. Roche excavated about 80 adult and more than 100 infantile skeletons of the Mechta-Afalou type, associated with an Ibero-Maurusian industry (Epipalæolithic). These remains give a carbon-14 date of 10,500–12,070 years according to the layers.

The adult sacra of that series are characterized by the presence of a more-or-less developed dehiscence of the crista sacralis mediana known as spina bifida. Spina bifida is a defect in the normal closure of the spinal column at any point; but its commonest site is in the lumbosacral area. In modern man, it is a rather frequent anomaly, since 14–24 per cent of the vertebræ of the lumbosacral junction are thus affected[1,2]. Some authors consider that the dehiscence of *S* I is normal. We have found this anomaly in 4 fossil sacra out of 15, that is, in 27 per cent of the cases; the two first apophyses were lacking in one of these bones.

At the present time, the dehiscence of the last processus spinosus of the sacrum is more uncommon. On 21 fossil pieces, only 5 were quite normal; 3 showed a perforation between the apophyses 3 and 4. In specimen XXVII (Fig. 1), the canal of which is open in its upper part to the top of *S* II, there is another perforation between *S* II and *S* III. In two bones, the canal is not closed at mid height of the fourth epiphysis which is divided into two in two other bones. This dehiscence goes up to the top of the fourth apophyse in three specimens and concerns the third apophysis in six sacra. Lastly, in specimen XI (Fig. 2), the whole canal is open, except at the level of the first processus spinosus.

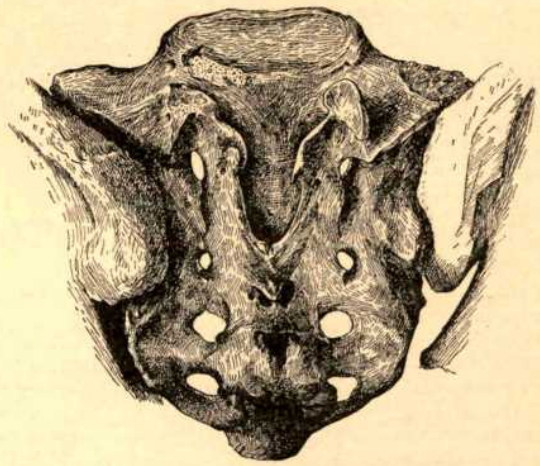

Fig. 1. Sacrum of the specimen XXVII showing perforations and a dehiscence of the upper processus spinosus

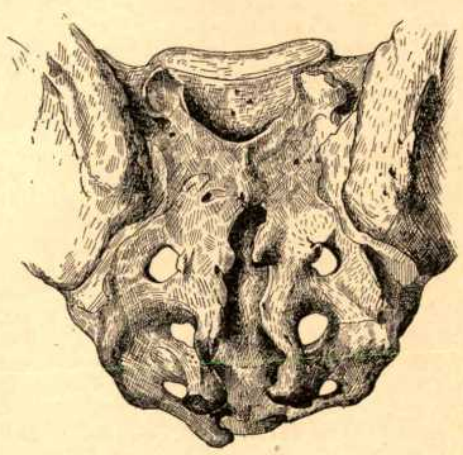

Fig. 2. Sacrum of the specimen XI, with an almost complete spina bifida occulta

If we do not take into account the pieces showing a perforation or an incomplete dehiscence of the half fourth apophysis, 10 specimens out of 21 appeared abnormal. If all the anomalies are considered, 16 specimens out of 21 should not be accepted as normal: such a percentage does not seem to be found at our time. As concerns prehistory, spina bifida occulta has been ascertained by L. Pales on a 5,000-year skeleton[3]; but we are not aware of group data.

The occurrence of spina bifida can be influenced both by environmental and genetic factors[4]. According to Shamburov[5], spina bifida occulta would be the heterozygous condition, of which spina bifida aperta, generally fatal in infancy, would be the homozygous counterpart. The first condition would therefore be due to a dominant gene, although we should remember that the mode of inheritance of spina bifida is considered by many human geneticists as least reliable[6].

The study of modern isolates has shown that a dominant gene can spread in a relatively short time. The high frequency of spina bifida in our series could signify that the inhabitants of Taforalt were highly endogamous.

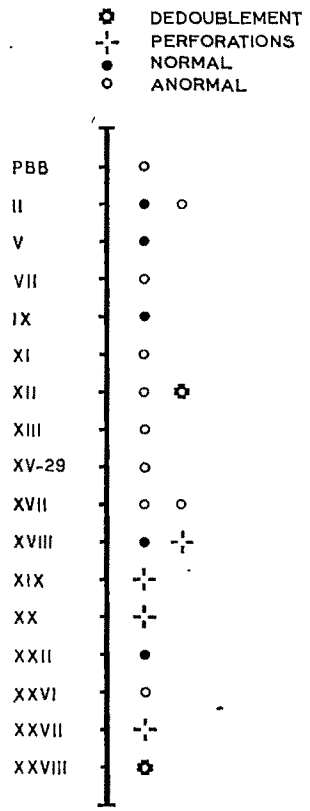

Fig. 3. Distribution of spina bifida according to the sepultures

It would also seem that there is an increase of that anomaly in time. The number of the tombs rather closely corresponds to the antiquity of the sepultures; we can see in Fig. 3 that from tomb XVIII to tomb XXVIII only one bone shows an actual dehiscence: this dehiscence is found in 9 sacra from tomb XVIII. This could suggest the diffusion of spina bifida by a dominant gene.

Criteria for the Comparison of Skulls

THE two essentials for the satisfactory comparison of skulls are a common plane of orientation and a centring point that is universally valid, that is, common to all skulls throughout the vertebrate series. There is urgent need for agreement on these two criteria and particularly on a common centring point.

Many planes of orientation have been devised[1-3]; but it is now generally agreed that the Frankfurt Horizontal is the most satisfactory for primates, at least (but see ref. 3). There are, however, differing views on the centring point, with the basi-cranial angle as a possible favourite.

There is one point in all vertebrate skulls which can be looked on as a universally valid morphological feature—that is, the frontal extremity of the notochord. This lies just within or immediately behind the pituitary fossa in all vertebrates[4]. In man this end of the notochord is temporarily attached to the posterior lobe of the pituitary gland[5]. In the human being, and possibly in most vertebrates, the frontal extremity of the notochord is finally encased in the posterior wall of the pituitary fossa. The posterior lobe of the pituitary gland or, more readily, the pituitary fossa should, therefore, provide a good common centring point for all skulls. It has the advantage, too, that it remains constant throughout the age-range of any animal.

If skulls are centred on the pituitary fossa (in practice the floor of the fossa is the most convenient point to choose) and orientated in the Frankfurt Horizontal an interesting series of relationships emerges.

In all human beings examined, of diverse ethnic origin (European, Chinese, Australian aborigine) and of ages ranging from neonatus to adult, the Frankfurt Horizontals were virtually coincident at the level of the inferior surface of the body of the sphenoid bone. In other primates (*Gorilla*, *Pan*, *Pongo*, *Macaca*, *Papio*) and a juvenile macaque (about six months old) the Frankfurt Horizontals were also virtually coincident but at a much higher level which crossed the middle of the pituitary fossa. A quadruped skull (*Ovis aries*) was examined on the same criteria and the Frankfurt Horizontal was found to be still higher, passing just above the pituitary fossa. Moreover, it could be shown that the level of the Frankfurt Horizontal was in each case related to the plane of the foramen magnum and hence to the angle at which the skull joined the vertebral column[6]. Use of the region about the frontal extremity of the notochord has, therefore, encouraging morphological justification.

Comparison of skulls on this basis offers no difficulty if they can be sectioned in the median sagittal plane. If they must be kept intact the pituitary fossa can usually be visualized satisfactorily in orthogonal or near-orthogonal X-ray plates. Should the radiographic detail be confusing—as it is in some of the larger apes—or obscured by mineralization the pituitary fossa can be identified by inserting a thin strip of lead through the foramen magnum and hooking it over the dorsum sellæ.

Some skulls are too heavily mineralized even for this expedient and many are so filled with dense matrix as to render the manœuvre impossible. Under such circumstances an alternative is sometimes available.

The correlative of the posterior lobe of the pituitary gland is the anterior lobe which migrates from the dorsal wall of the naso-pharynx as the pouch of Rathke to reach the pituitary fossa. The point of departure from the naso-pharynx is where the posterior border of the root of the vomer joins the body of the sphenoid. This point is frequently marked by a pit on the underside of the sphenoid. It is called the 'hormion' in physical anthropology. It serves as a useful substitute for the pituitary fossa as a common cranial centre and can be used in heavily mineralized skulls and in skulls solidly filled with matrix provided the region is clean and intact. The hormion can even be used on casts if they are accurately made. The hormion is not quite so accurate as the pituitary fossa because the depth of the body of the sphenoid varies from skull to skull but it is certainly more precise than most of the centring points utilized so far.

MISCELLANEOUS

Explosion in an Autoclave caused by Cellulose Nitrate Tubes

The practice adopted in biological laboratories when disposing of contaminated material is to sterilize by steam in an autoclave, taking care to exclude anything known or suspected to lead to combustion. A latent danger exists if certain types of laboratory ware are treated in this way, without the research worker being aware that risk exists. An example of this occurred in this Establishment when a number of celluloid centrifuge tubes, potentially contaminated and intended for destruction, were sent for autoclaving. During the process spontaneous ignition of the tubes occurred, followed by explosive burning. The autoclave was wrecked and extensive superficial damage was done to the surrounding areas.

Although it can scarcely be regarded as good practice to autoclave material based on cellulose nitrate it is not patent that an explosion hazard exists. Information issued by the suppliers of the tubes in question includes reference to the inflammability of cellulose nitrate and the statement that they "cannot be autoclaved", but the statement doubtless means that the tubes are ruined by the treatment and gives no indication that the operation is potentially dangerous; it is possible that the chance of combustion is so small that there is no record of such an occurrence.

The circumstances in which the explosion occurred are both interesting and instructive. A number of unused celluloid tubes made for use with the ultracentrifuge were found to be unserviceable, having shrunk as a result of ageing for several years. The room in which they had been stored was used for work involving toxic materials, and it was decided to autoclave them as a safety precaution before discarding. The autoclaving procedure was a standard two-cycle operation, each cycle consisting of evacuation of the sterilizing chamber followed by admission of steam until a pressure of 20 lb./in.^{2} and a corresponding temperature of 125° was achieved and maintained for a prescribed period. The explosion occurred at the beginning of the second cycle at a point where the steam pressure was approaching the operating level of 20 lb./in.^{2}.

Examination of the recording instruments showed that no malfunctioning of the equipment had occurred. The probability that spontaneous ignition of the tubes was responsible for the accident led to tests being conducted at the Explosives Research and Development Establishment, Waltham Abbey. The tests demonstrated the thermal instability of some of the samples examined, and convincing proof of the cause of the explosion was obtained when an attempt to reproduce the explosion in simulated conditions was successful. From the various tests carried out at Waltham Abbey it was possible to attribute the cause of the accident to a combination of three factors; (1) age of the tubes; (2) temperature in the autoclave; (3) presence of water vapour.

The conditions needed to produce spontaneous combustion at such a low temperature are surprising to anyone who is not an explosives expert. In addition, the probability of the event and its severity are respectively dependent on the mass of material involved and the ratio of combustible mass to free volume of the chamber. In this explosion both the mass and the mass/volume ratio were high. Nevertheless, it is clear that material made from cellulose nitrate may present an explosion hazard when autoclaved and alternative methods of decontamination and destruction should be employed.

I thank colleagues at Waltham Abbey for verifying the cause of the accident.

Life Tables

It is a pity that in reviewing the series of life tables recently compiled by Dr. R. A. M. Case *et al.*[1], Prof. L. Hogben has ignored the historical facts and thereby implied that actuaries have not only been unaware of the principles of cohort analysis in particular but also that their methods have also been of disservice to the public.

In point of fact the use of the life table (the adjective actuarial is redundant since all such tables are actuarial) was first introduced to research workers by William Farr about a hundred years before R. R. Kuczynski, and its use was re-inforced so far as the medical officers of health were concerned by George King in 1914 (ref. 2).

The limitations of life tables based on mortality rates experienced in a particular calendar year (or period of consecutive years) have long been appreciated by actuaries and the tables derived from the mortality of life office annuitants for 1900–20 (ref. 3), and also those derived from the mortality of Government annuitants for the same period[4], were both constructed on the principle of a cohort analysis of the recorded rates of mortality. In 1927 a paper was presented to the Institute of Actuaries by V. P. A. Derrick[5], which directed attention to the advantages gained from analysing mortality rates by generations rather than by calendar year, and similar thoughts were behind a paper presented to the Faculty of Actuaries by A. R. Davidson and A. R. Reid in the same year[6]. In 1936 the official journal of the Scandinavian actuarial societies published a paper by Cramér and Wold[7] in which a series of generation mortality curves were constructed from Swedish population data; while in 1953 the Institute and Faculty of Actuaries[8] published a volume of annuity tables which contained a series of hypothetical generation tables of mortality appropriate to annuitants. It is therefore inaccurate to imply that the method of cohort analysis is foreign to actuarial thought.

On the question of the use of actuarial expertize in the construction of English Life Tables it is important not to overlook that such tables have to serve many different purposes; in particular, the allegation of actuarial gamesmanship scarcely does justice to the painstaking efforts by the Registrar General to point out the limitations of a life table based on the combination of many generations. The construction of a life table must have some regard to the purposes for which it is intended to be used and the requirements for calculations appropriate for insurance company operations (where smoothness is important) will differ from those of the medical research worker.

The implied assumption that Greville's method is the only method of constructing abridged tables is also at variance with the facts. The supplement to the 75th Annual Report of the Registrar General (Cd. 7512, 1914) shows ample support of the use of abridged methods, and a comparison of seven different methods with the relative computation times has been available for some years[9]. It could also be argued that the method adopted by the Registrar General for constructing the abridged life table which appears annually in the September *Quarterly Return* has more common sense than Greville's method, the rationale of which involves assumptions regarding the analytical form of the rate of mortality.

FORTHCOMING EVENTS

Tuesday, July 9

JOINT HEALTH PHYSICS COMMITTEE, BRITISH OCCUPATIONAL HYGIENE SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 9.30 a.m.—Conference on "Legislation and Codes for the Safe Use of Ionising Radiation".

Tuesday, July 9—Thursday, July 11

ASSOCIATION FOR THE STUDY OF ANIMAL BEHAVIOUR (in the Meeting Room of the Zoological Society of London, Regent's Park, London, N.W.1), at 10 a.m. on Tuesday and Thursday, and 9.50 a.m. on Wednesday—Symposium on "Foraging and Feeding Behaviour".

Wednesday, July 10—Friday, July 12

INSTITUTE OF PHYSICS and the PHYSICAL SOCIETY (at the University of Oxford)—Conference on "High Magnetic Fields, Their Production and Their Applications".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER or ASSISTANT LECTURER IN STATISTICS—The Registrar, The University, Keele, Staffs (July 12).

LECTURER IN CHEMISTRY, primarily to assist in the teaching of physical or industrial chemistry—The Secretary, Welsh College of Advanced Technology, Cathays Park, Cardiff (July 13).

PHARMACOLOGIST, to investigate changes in the composition of body fluids in migraine—Prof. M. Weatherall, The London Hospital Medical College, Turner Street, London, E.1 (July 13).

RESEARCH ASSISTANT (with a good honours degree in physics) to Dr. J. E. Enderby, for an investigation of the structure of liquid metals and alloys using neutron methods—The Registrar, The University, Sheffield 10 (July 13).

RESEARCH ASSISTANTS (with a diploma in technology or university degree in electrical engineering, and preferably experience in industry), to work with Dr. D. Karo, Reader in Light Current Electrical Engineering, in one or more of the following fields: power generation by means of semiconductors; non-destructive testing; instrumentation and telemetering; new materials in electrical engineering; supraconductivity and cold temperature phenomena; and development of novel instruments—The Staff Officer, College of Advanced Technology, Gosta Green, Birmingham 4, quoting Ref. 6/63/6 (July 13).

SCIENTIST (Lecturer or Assistant Lecturer grade) IN THE CANCER RESEARCH DEPARTMENT, Caterham, to investigate the biochemistry of tumour growth—The Secretary, Marie Curie Memorial Foundation, 124 Sloane Street, London, S.W.1 (July 13).

SENIOR LECTURER IN THE DEPARTMENT OF PSYCHOLOGY—The Registrar, The University, Leicester (July 13).

DIRECTOR OF THE CRIPPS COMPUTING CENTRE, to be responsible for the development of computing facilities throughout the University, together with the associated advisory services and appropriate research and teaching—The Registrar, The University, Nottingham (July 15).

JUNIOR LECTURER (qualified in palæontology and stratigraphy) IN GEOLOGY—The Registrar, Trinity College, Dublin 2, Republic of Ireland (July 15).

RESEARCH ASSISTANT (with experience in tissue culture and mammalian chromosome techniques) IN THE DEPARTMENT OF PATHOLOGY, for research on congenital abnormalities—The Secretary, The University, Edinburgh (July 15).

ASSISTANT LECTURER (honours graduate in physics, and preferably an interest in electronics) IN THE DEPARTMENT OF PROSTHETICS, Turner Dental School—The Registrar, The University, Manchester 13 (July 16).

ASSISTANT LECTURER (with a degree in science with chemistry as a major subject, industrial experience, and preferably teaching experience) IN CHEMISTRY at Bendigo Technical College, Bendigo, Victoria, Australia—Council for Technical Education and Training for Overseas Countries, 12 Lincoln's Inn Fields, London, W.C.2 (July 17).

EXPERIMENTAL OFFICER or SENIOR EXPERIMENTAL OFFICER (with some years of experience in metallurgy or physics, and preferably experience of an electron-microscope or micro-probe analyser) IN THE DEPARTMENT OF METALLURGY, to assist in work on creep in precipitation hardening alloys, with particular reference to electron-microscopy—The Registrar, The University, Manchester 13 (July 17).

LECTURER IN PHYSICS—Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (July 17).

RESEARCH ASSISTANT (graduate in electrical engineering or physics) IN THE DEPARTMENT OF METALLURGY, to assist in the development of methods for the measurement of energy dissipation in vibrating metals—Prof. K. M. Entwistle, Department of Metallurgy, The Manchester College of Science and Technology, Manchester 1 (July 17).

RESEARCH ASSISTANT (well qualified in sociology and interested in its application to education) TO THE PROFESSOR OF EDUCATION—The Registrar, The University, Keele, Staffs (July 19).

SENIOR LECTURERS and LECTURERS IN MATHEMATICS at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Brisbane and London, July 19).

LECTURER IN THE DEPARTMENT OF GEOLOGY AND MINERALOGY—The Secretary, The University, Aberdeen (July 20).

LECTURER (with a special interest in virology and microbial genetics) IN THE MICROBIOLOGY DEPARTMENT—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (July 20).

SENIOR LECTURER and/or LECTURER IN THE DEPARTMENT OF BIOCHEMISTRY—The Registrar, The University, Sheffield (July 20).

ASSISTANT LECTURER (preferably with an honours degree or higher degree in physiology, and a veterinary or medical qualification) IN THE DEPARTMENT OF VETERINARY PHYSIOLOGY—The Secretary, The University, Edinburgh (July 22).

ASSISTANT LECTURER (with an interest in general experimental psychology) IN PSYCHOLOGY—The Registrar, The University, Keele, Staffs (July 22).

BIOCHEMIST (with M.Sc. or Ph.D. in biochemistry or physiological chemistry or equivalent, and at least three years satisfactory experience of biochemistry or chemical pathology) for the Cork Health Authority—The Secretary, Local Appointments Commission, 45 Upper O'Connell Street, Dublin 1, Republic of Ireland (July 23).

LECTURER IN ANTHROPOLOGY; and a SENIOR TUTOR IN ANTHROPOLOGY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, July 26).

SUB-LIBRARIAN (with a good honours degree and preferably relevant experience and professional qualifications) IN THE FACULTY OF ENGINEERING—The Registrar, The University, Liverpool, quoting Ref. No. CV/348/N (July 26).

ASSISTANT LECTURER IN STATISTICS (in the Unit of Biometry), for work which will involve teaching, consulting and research—The Registrar (Room 22, O.R.B.), The University, Reading (July 27).

EXPERIMENTAL OFFICER (with a university degree in science, veterinary science, rural science, agricultural science or equivalent qualifications, and experience in physiology or biochemistry, for example, clinical biochemistry), AT THE CATTLE RESEARCH LABORATORY, Division of Animal Genetics, Commonwealth Scientific and Industrial Research Organization, Rockhampton, Queensland, to assist in a research programme on the physiology of cattle, which includes the study of digestive processes, gross energy metabolism, and various aspects of biochemistry and metabolism—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 682/19 (July 27).

SENIOR RESEARCH FELLOW in one of the following fields in the Faculty of Science: Civil Engineering, Computer Engineering, Electrical Engineering, Mechanical Engineering, Mechanics of Fluids, Metallurgy, Nuclear Engineering or Soil Mechanics—The Registrar, The University, Manchester 13 (July 29).

LECTURER IN MYCOLOGY at Fourah Bay College, The University College of Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 30).

BIOMETRICAL GENETICIST IN THE PLANT BREEDING SECTION OF THE DEPARTMENT OF AGRONOMY, Waite Agricultural Research Institute, to undertake biometrical research associated with fundamental and applied aspects of breeding self- and cross-pollinated plant species; lecturing duties will be light—The Registrar, University of Adelaide, Adelaide, South Australia (July 31).

LECTURER IN ORGANIC CHEMISTRY at the University of Adelaide—The Registrar, University of Adelaide, Adelaide, South Australia (July 31).

LECTURER or ASSISTANT LECTURER IN PARASITOLOGY (Medical Helminthology) at the University of Singapore—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (July 31).

LECTURER (with a good degree in electrical engineering or in solid state physics or solid state chemistry) IN THE MATERIALS SECTION OF THE DEPARTMENT OF ELECTRICAL ENGINEERING, to take part in undergraduate and postgraduate teaching and to engage actively in materials research—Dr. J. C. Anderson, Electrical Engineering Department, Imperial College, London, S.W.7 (August 1).

RESEARCH OFFICER or SENIOR RESEARCH OFFICER (Veterinary Bacteriologist) (with a degree in veterinary science, or its equivalent, together with a Ph.D. degree or postgraduate research experience of an equivalent standard and duration supported by satisfactory evidence of research ability in a relevant field of bacteriology and immunology) IN THE MCMASTER ANIMAL HEALTH LABORATORY, Commonwealth Scientific and Industrial Research Organization, Sydney, to continue and further develop the research programme on footrot and other diseases of the feet of sheep—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 202/220 (August 3).

PROFESSOR OF PSYCHOLOGICAL MEDICINE at the University of Queensland, Brisbane, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, August 9).

LECTURER and an ASSISTANT LECTURER IN THE MECHANICS OF FLUIDS in the Faculty of Science—The Registrar, The University, Manchester 13 (August 15).

LECTURER or SENIOR LECTURER IN PHYSICS at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 15).

LECTURER (preferably with interests in the field of terrestrial or freshwater ecology) IN ZOOLOGY at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, August 15).

SENIOR LECTURER IN PHYSIOLOGY with emphasis on Histology—The Secretary of University Court, The University, Glasgow (August 15).

ANDERSON CHAIR OF PSYCHOLOGY—The Secretary, The University, Aberdeen (August 17).

CHAIR OF APPLIED MATHEMATICS at the University of Tasmania—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 19).

LECTURERS (2) (with special qualifications in inorganic, structural or physical chemistry) IN CHEMISTRY at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, August 31).

RESEARCH FELLOW (with experience in archæological exploration and survey and preferably at home in other of the field sciences) IN PREHISTORY at the Institute of Advanced Studies, Australian National University, to initiate, prosecute and direct archæological work in Papua/New Guinea—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 31).

SENIOR LECTURER (qualified optometrist with postgraduate training and research interests in physiological optics and visual perception) IN OPTOMETRY IN THE DEPARTMENT OF PSYCHOLOGY, University of Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, August 31).

READER IN MICROBIOLOGY—The Clerk to the Governing Body, Battersea College of Technology, London, S.W.11 (September 1).

LECTURER (well qualified in engineering science or applied mathematics with engineering experience) IN MECHANICAL ENGINEERING at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, September 2).

CHAIR OF PHYSICS; and CHAIR OF MATHEMATICS IN THE SCHOOL OF MATHEMATICAL AND PHYSICAL STUDIES—The Registrar, University of East Anglia, Earlham Hall, Norwich, NOR. 05G (September 7).

DIRECTOR OF THE UNIVERSITY OF SHEFFIELD INSTITUTE OF EDUCATION—The Registrar, The University, Sheffield (September 7).

ASSISTANT EXPERIMENTAL OFFICER (with at least G.C.E. in five subjects including two scientific subjects at advanced level or equivalent; or, at

age 22, a pass degree or equivalent), for biological work on the insecticidal control of stored-product insects—The Director, Pest Infestation Laboratory, Agricultural Research Council, London Road, Slough, Bucks.

Assistant Professor or an Associate Professor (physiologist or biochemist, M.D. and/or Ph.D.) in the Department of Physiology—Prof. M. Beznak, University of Ottawa, Ottawa, Ontario, Canada.

Demonstrator (with a good honours degree in chemistry or biochemistry, or agricultural chemistry) in Food Science in the Department of Agricultural Sciences at the School of Agriculture, Sutton Bonington—The Registrar, The University, Nottingham.

Experimental Officers and Assistant Experimental Officers (with at least two G.C.E. "A" level scientific subjects, if over 22, H.N.C. pass degree or equivalent) at the Chemical Defence Experimental Establishment, Porton, near Salisbury, for research and development work on a wide range of problems in physics, chemistry, and experimental biology and physiology—War Office C.5F, London, S.W.1.

Graduate Physicist in the Medical Physics Department, to assist with radioactive isotope studies—The House Governor, St. Mary's Hospital, Paddington, London, W.2.

Head of the Department of Chemistry and Geology (Grade IV)—The Principal, Kingston College of Technology, Penrhyn Road, Kingston-upon-Thames, Surrey.

Junior or Student Technician in the Surgical Unit, to assist in research on organ transplants and cancer treatment—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W.2.

Lecturer in Physical Chemistry; a Senior Lecturer in Mathematics; and an Assistant Lecturer (Grade B) in Mathematics—Clerk to the Governing Body, Borough Polytechnic, Borough Road, London, S.E.1.

Physiologist (with biochemical interests), to work in the pressure chamber at the Western Infirmary, Glasgow—Sir Charles Illingworth, Department of Surgery, The Western Infirmary, Glasgow, W.1.

Postdoctoral Research Associate in Experimental Spectroscopy—Personnel Office, Harvard University, 1352 Massachusetts Avenue, Cambridge 38, Mass., U.S.A.

Research Assistant (with a good honours degree in biochemistry, together with some research experience) in Biochemistry in the Urological Surgery Division (Renal Research Unit of the Department of Surgery), to participate in research into protein metabolism in renal disease—The Registrar, The University, Leeds 2.

Research Assistant (with a good honours degree, or diploma in technology, in physics) in the Physics Department, preferably for work on gas discharges—Head of the Physics Department, Northern Polytechnic, London, N.7.

Research Officer (Entomologist) (with an honours degree in biology with appropriate postgraduate experience and a national of, and permanently resident in, Great Britain or the Republic of Ireland), to plan and carry out research on the biology of malaria-carrying mosquitoes in East Africa, and to direct field and laboratory work of an established entomological research team—The Director of Recruitment, East African Common Services Organization, 3 Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting Ref. RC318/145/02.

Scientific Officer (honours graduate, preferably in biochemistry, agricultural chemistry or chemistry), to work, both in laboratory and with experimental animals, primarily on nutritional problems in pigs—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref. 63/7.

Scientific Officer in the Department of Grass/Animal Ecology, to undertake, as part of a team studying the ecology of the grazing animal, research into problems of animal health and performance arising out of the application of recently developed techniques in both animal and pasture production—The Secretary, The Grassland Research Institute, Hurley, Maidenhead, Berks.

Senior Technician (Grade I or II) in Biochemistry at the Midland Centre for Neurosurgery and Neurology, Holly Lane, Smethwick—The Group Secretary, West Bromwich and District Hospital Management Committee, West Bromwich and District Hospital, West Bromwich.

Technician (preferably with experience in histological techniques) at the Marine Science Laboratories, Menai Bridge—The Registrar, University College of North Wales, Bangor, North Wales.

Technician (with A.I.M.L.T. in pathological chemistry or Final Certificate (Chemistry or Biochemistry), City and Guilds of London, or A.I.S.T.), for biochemical research—The Secretary, University College Hospital Medical School, University Street, London, W.C.1.

SCIENCE AND THE INTELLECTUAL TRADITION

BY those who heard it, Dr. S. Toulmin's address to Section L, "Science and Our Intellectual Tradition", was reckoned to be one of the outstanding addresses at the 1962 meeting in Manchester of the British Association for the Advancement of Science: it has now been published in the May issue of *The Advancement of Science*—the bi-monthly journal of the Association.

Dr. Toulmin's questioning of the fragmentation of science makes stimulating reading in the light of questionings along similar lines in the United States, for example, Mr. M. K. Hubbert's presidential address to the Geological Society of America last November, in which he argued that science in the United States of America was in a state of confusion (*Science*, 139, 884; 1963). Further, some remarks of Dr. Toulmin regarding education are particularly apposite reading in the light of Prof. Kenneth Denbigh's observations in a recent book, *Science, Industry and Social Policy*, and Lord Hailsham's desiderata for education in science in *Science and Politics* (see *Nature*, 198, 1023, 1123, 1125; 1963).

Dr. Toulmin begins by pointing out that in education, as in some other spheres of human life, the direction of our thinking is deeply affected by the system of general, unexamined assumptions characteristic of our day and age and suggesting that we may now be at a turning-point, so that in the second half of the twentieth century our intellectual environment may differ widely from what it has been during the first half. In particular, he suggests that there are signs that the drive towards intense and concentrated specialization may be checked and that there is at last a real drive to re-integrate the specialist disciplines into which our educational habits have become fragmented and to set them working together in the service of a fuller understanding. This new current of thought is exerting its influence, he thinks, all over the intellectual scene, and he instances the growing impatience with class parties and rigid nationalism in politics, the attention being given in the universities to new forms of faculty structure and, within science itself, the desire to apply the technical gains of the past five or six decades to the re-integration of intellectual life.

Evidence in support of Dr. Toulmin's view is easily discerned in Lord Hailsham's writings, but when he discusses science and more particularly the conflict between the Athenian and Alexandrian elements in our scientific tradition, Dr. Toulmin goes much deeper. He suggests that the fundamental reason why Greek scientists failed to follow up thoroughly the ideas of Archimedes and Hipparchus was a failure of intellectual nerve. With the transition to Alexandria, science, from being 'natural philosophy', became a kind of intellectual technology. In the sixteenth century, scientific enquiry at a really profound level revived, not because of some supposedly novel experimental method, but because the old Ionian confidence had revived. For the next four centuries, as for those following 550 B.C., the mainspring of scientific progress has been philosophical, not technological, and the Athenian impulses at the heart of modern science have fired the imagination of literary men in both periods.

Now, however, science is becoming increasingly dominated by Alexandrian forces which threaten once again to reduce it from being regarded as natural philosophy to being considered as "an assemblage of skills—practical, technological, theoretical and mathematical". The sheer pressure of finance and patronage is siphoning off hands and brains into 'gadgeteering', most of it without serious hope of philosophical fruit. On Athenian considerations, he argues, our money would be going not into space flight or research but into international co-operation in nuclear physics, into molecular biology, embryology, psychopharmacology and ethology, apart from the other behavioural sciences. He believes there is real danger that our obsession with technique may stifle the natural philosophy from which it sprang.

If Lord Hailsham had any misgivings as to concluding his book on a philosophical note, they should be removed by Dr. Toulmin's impressive argument. Even more noteworthy, however, is the resemblance between this conclusion and that reached by Mr. Hubbert from a much more pragmatic review of the position of science in the United States. Challenging strongly the way in which the prevailing academic system of preferment, with its criterion of publication and output for research, favours the opportunist capable of producing scientific trivialities in large numbers as against the true scholar working on difficult and important problems the solution of which may demand years of concentrated effort, Mr. Hubbert is critical of the whole transition of educational into research institutions in the United States. This he regards as definitely retrogressive and threatening to science, the Government contract-grant system being a main contributory factor. In consequence of this neglect by the universities of their primary responsibilities as institutions of learning and education, scientists in the United States appear to have lost sight of their intellectual foundations and resorted to authoritarianism.

Mr. Hubbert's analysis is, however, deeper than this brief summary would suggest, and his ultimate thesis is that the present confusion and tendency to authoritarianism arise from a fundamental misconception of the nature of science and its evolution. Evolution here is not a progression from the simple to the complex but from the complex to the simple. Advance is always in the direction of reducing the initial chaos to a form within the scope of human comprehension, and without denying the value of co-operative team work he insists that thought is essentially an individual activity and that the greatest of scientific achievements have almost invariably been the work of individuals.

In his judgment, therefore, the primary condition of a renaissance in education, in scholarship and in science is to attempt to achieve an atmosphere congenial to individuals of the type of Gallileo, Kepler, Newton, Darwin or Willard Gibbs. The universities must become institutions of learning again, and be provided with more orderly support. Competent teaching must receive the respect it deserves and the curriculum so revised that it is mandatory for students to receive a working knowledge of the fundamental principles of science. The preoccupation

with trivialities that pass for research must go and with it book-keeping based on the number of papers published in a year.

Dr. Toulmin's discussion and analysis of education is more detailed, and though he prescribes with some reserve, the conclusion is not dissimilar. He, too, challenges the autonomous claims of the different academic disciplines, suggesting that instead of thinking in terms of two cultures we should think rather of the different subjects as different approaches to, and departures from, the common core of questions and ideas which originally formed the intellectual tradition of Europe, and is now shared by the whole world. Dr. Toulmin, however, suggests a picture: we should think of the different academic disciplines, not as separate entities, but as the segments of a fan, overlapping at the centre but branching off from there in different directions, or perhaps, better still, as the different branches of a tree, which have all sprung, and draw their life, from a common trunk.

The overlapping region, the common ground, or common trunk, which all the subjects share is the central core of ideas on which they all alike have a bearing. Science, for example, unites the tradition of natural philosophy with a collection of mathematical and manual skills, and, as Dr. Toulmin shows, the bodies of general ideas in all the subjects he instances are related to one another far more closely than their different skills and techniques. While we cannot afford to undervalue these techniques, since they represent the proper contribution which each subject can make to the progress of our common intellectual debate, they derive their sap, value and interest, their intellectual justification, from their connexion to a central body of general questions and ideas. They are not self-sufficient ends.

Dr. Toulmin does not question that some of the forces that have driven disciplines apart are respectable enough; however, he does suggest that it is time to think afresh not simply about our preoccupation with techniques and skills but about those administrative and pragmatic forces which in universities and elsewhere have tended to divert education away from general ideas and critical habits of mind, and towards the inculcation of skills and abilities. The importance of the experiments already being undertaken in the University of Keele, the University of Sussex and that contemplated at Norwich, or the exciting opportunities which confront these new institutions generally could scarcely be better displayed though they are not specifically mentioned. At least it is on the universities rather than the schools that he places the responsibility for the missing element in our education to-day—for the lack of the sense that the things being taught, learned and examined are living parts of a larger, developing unity, of our intellectual tradition. The schools cannot ensure that students of science no longer leave school devoid of deep understanding, even of their own professional schools, or unaware of the common traditions they share and the mutual relevance of even their own subjects unless the universities co-operate in clearing away the sandbanks built up during the first half of this century.

The problem of examinations is at the heart of Britain's practical quandary and the present fragmentation will persist just so long as the examinations for the General Certificate of Education remain geared-up to test for skills and factual knowledge rather than for understanding and a grasp of general ideas. It is not enough, Dr. Toulmin continues, for matriculation boards to exhort teachers to watch their pupils' English expression and powers of criticism: "until the Boards resolutely enforce demands for adequate intellectual grasp lucidly expressed—to the point of failing mere performers, however skilled—the general run of schools will have no sufficient motive for taking on the admittedly harder aspects of education". Despite, however, the support to be found for his views, Dr. Toulmin is not optimistic as to the chances of developing the new attitudes needed short of the establishment of some new examining body, such as a 'New Universities' Examining Board', able to create from scratch the educational organization appropriate to the need, nor is optimism warranted by the fact that something of Dr. Toulmin's approach is to be found in an address by Dorothy M. Emmet on "Science and the Unity of Thought" at a symposium in Manchester almost twenty years ago.

Nevertheless, the soil is now much better prepared for Dr. Toulmin's ideas to take root. Something of his outlook is to be found in an address by H.R.H. the Duke of Edinburgh to the Association for Science Education on April 26. Quoting Prof. J. H. Plumb's remark criticizing the reticence and ambiguities of historians and their reluctance to accept the social responsibilities that their subject imposed on them, and asserting that the prime activity of history should be to teach non-historians not to perpetrate its own practitioners, the Duke remarked that science also needed to teach non-scientists as well as to train its own practitioners, with the added responsibility of providing for a rapidly changing environment. He added that no valuable work could be done to-day in any academic subject or in industry and commerce without some basic knowledge of science, and that applied science demanded at least an understanding of social development and pure science some appreciation of its historical background. The Duke suggested that the intensity of the discussion over the relative importance of science and the humanities tended to obscure more important issues from the community at large and to overlay the common ground which a director of scientific research, a business manager or a bishop, for example, might share as administrators.

While the Duke of Edinburgh, at this point, was concerned to stress the importance of a scientific approach to management, irrespective of whether particular scientific or professional knowledge was also needed, his observation illustrates another point arising out of Dr. Toulmin's paper. It is this understanding of our common intellectual traditions, including appreciation of the scientific approach, that must form the substance of the science which the ordinary citizen requires. Beyond that, however, the appreciation of the magnitude of that common ground and tradition could help to check fragmentation in other directions that is also detrimental to modern society. In a paper, "Interaction of Technologies", also given at the British Association meeting in Manchester (see *Nature*, 197, 222; 1963) and also published in the May issue of *The Advancement of Science*, Mr. L. Holliday develops the thesis that fundamental advances in technology are more likely to accrue from searching for the fundamental principles in individual technologies, and for the relations between them than from pursuing the usual practice of studying them by industries. It follows that a more analytical approach to technology as a whole is required, and that technologists should be encouraged to look beyond their individual specialities.

Deprecating the multiplicity of technological societies, institutions and journals, Mr. Holliday, like Dr. Toulmin, to this end visualizes considerable changes in the structure of university departments of technology and of colleges of technology. Equally important, he suggests a radical reorganization of the industrial research associations into larger units in which resources for really effective fundamental research would be available. To shift in this way from a multiplicity of associations based on different industries to one based on some eight or nine technologies would present the Department of Scientific and Industrial Research with a formidable task, probably even more in respect of education and of finance than of organization and location. However, Mr. Holliday is on solid ground in making the suggestion, and Dr. Toulmin's argument gives him firm support.

This alone illustrates how much more is at stake in this question of safeguarding intellectual traditions than educational organization alone. Some of the fringe benefits, as it were, have already been indicated, as in Mr. Holliday's proposals. Another might well be an increased supply of competent technicians instead of the threatened shortage, if matriculation boards, for example, began to fail the mere performers who show insufficient intellectual grasp and directed them to the technical schools and colleges for training as technical assistants. It is, however, for its effect on the intellectual attitudes of the two new generations that a re-united and well-directed educational system is most imperative. The future of science and much else depends, as Dr. Toulmin and Mr. Hubbert both agree, on the ability of those two generations to sustain the Athenian attitudes of mind, whose critical probing and speculative freedom have been the main stimulus of scientific growth. Dr. Toulmin has provided the essential criteria by which the forthcoming proposals of the Robbins Committee should in due course be assessed.

CURRENT PROBLEMS IN VERTEBRATE PALÆONTOLOGY

Problèmes Actuels de Paléontologie (Évolution des Vertébrés)

(Colloques Internationaux du Centre National de la Recherche Scientifique, No. 104, Paris, 29 Mai–3 Juin, 1961.) Pp. 474. (Paris: Éditions du Centre National de la Recherche Scientifique, 1962.) 62 N.F.

IN June 1961 a colloquium was held in Paris on vertebrate palæontology, and the papers read, together with the discussions, are now published in book form. Two such meetings have previously been held in Paris, in 1947 and 1955, and the latest coincided with the opening of the new palæontology laboratories in the Institut de Paléontologie, Muséum National d'Histoire Naturelle. Prof. Lehman, director of the Institute, is to be congratulated on the excellence of the laboratories, the success of the colloquium which he was responsible for organizing and for the high standard of the proceedings which he has edited.

The papers in the volume rather remind one of company reports to boards of directors. It is assumed the board will know the background and wish only to hear of the year's progress. Some reports detail clear and important advances, some have little that is new to record, few introduce any startling new innovations. Evolution of the phylum Chordata is stated to be the theme of the colloquium. Of the 43 papers offered, 11 deal with fish groups, 10 with reptiles and 22 with mammals (and of these 5 deal exclusively with primates). Yet despite the weighting in favour of the higher vertebrates, papers on the lower vertebrates deal with more fundamental problems. Mammalogists are largely, when not talking monkeys, concerned with faunal problems, stratigraphy and geographic distribution. The fish and reptile enthusiasts are concerned with the origin of major groups and their affinities, phylogenies, functional anatomy and the evolution of particular organs—ear, scales, rostrooral region.

Among the papers on lower vertebrates outstanding are those of the Stockholm school, from Stensiö, Ørivg and Jarvik. Stensiö gives a concise account of his lepidomorial theory concerning the nature of the placoid scale. The work was stimulated by studies made on edestid elasmobranchs from the Upper Permian of East Greenland. All early elasmobranchs and holocephalans, up to and including Carboniferous forms, possess 'cyclomorial' scales, that is, scales that grow by marginal additions of concentric zones of growth, while all post-Permian forms to the present day possess only placoid scales. The Permian edestids have both cyclomorial and placoid scales and in them the development can be traced through partial to total reduction of growth zone. The cyclomorial scale itself is formed of a fusion of small elements—lepidomora. These studies, supported by a vast wealth of detailed observations, some of which have already appeared in print, represent a major advance. Stensiö and his colleagues are not the first to tackle the evolutionary problems of scale histology, but the first for many decades and by far the most thorough; so thorough that it is important not to lose sight of the overall patterns. Ørvig, who has collaborated closely with Stensiö on the placoid problem, contributes an interesting paper in which he argues the affinity of ptyctodont arthrodires with holocephalans. A new Devonian ptyctodont, *Ctenurella*, from Germany allows detailed comparison of cranial anatomy to be made with holocephalans. Ørvig concludes the latter are nearer arthrodires than bradyodonts, that the two groups may have a common arthrodire ancestor or share direct lineal descent. Jarvik has in earlier work championed a diphyletic origin for the amphibia, deriving anura from osteolepid crossopterygians and urodeles from porolepid crossopterygians. In the present paper he develops his ideas on descent of urodeles from porolepids, basing his thesis largely on the anatomy of snout and branchial regions. Another fish paper worth noting is Lehman's account of the double articulation in arthrodires and its importance in swimming.

Olson re-approaches the problem of reptile origins. He stresses the lack of evidence at critical points and characteristically emphasizes the importance of environmental adaptation, especially to food supplies—a theme he developed so successfully in his great paper on the Permian faunas of the United States and the U.S.S.R.[1]. Olson considers that among the first tetrapods two main adaptive trends can be distinguished, the predator fish-feeders and the small aquatic carnivorous types. He recognizes three early streams of reptile evolution, seymouriamorph—diadectid—chelonian, captorhinomorph—synapsid and captorhinomorph—milleretid—diapsid, with Sauropterygia and Ichthyopterygia more likely to originate in the middle than the latter stream. Haas gives a detailed account of the mandibular musculature of snakes and deduces from this study relationships similar to those based on other morphological data. Hoffstetter reviews critically recent work on squamate classification, but concludes that the time is not yet ripe to draw up a phylogenetic table.

Lavocat returns to the enigma of rodent origins, dwells on the conflicts between anatomical lines of evidence and geographic distribution, implies that sciurognathous and hystricognathous are more meaningful than sciuromorph and hystricomorph, and favours the evolution of similar structures in different parts of the world. Kermack

measures the degree of mammalization achieved by late Triassic times and concludes that through the Mesozoic mammalian evolution was slow and regular. Russell has examined the only two known Palæocene mammal faunas from Europe, Cernay and Walbeck. His detailed studies are keenly awaited and in a short paper he compares the composition and environmental niches of the two faunas. Cernay, with yields of about 7,000 teeth, is characterized by multituberculates, meniscotheriid condylarths, primates, insectivores and creodonts. Walbeck has yielded about 4,000 teeth, the species are more varied, insectivores and creodonts are dominant and herbivores poorly represented. Russell suggests slight age differences, and indicates that the faunal unbalance at Walbeck could be due to preservation bias as well as to ecological differences. Brink's experimental work on stereophonic hearing in dogs, while scarcely conclusive, is important in illustrating the sort of investigation that demands serious attention. Deschaseaux throws light on differing evolutionary trends in the brains of bats, brontotheres and rhinoceroses, and differentiates between fixed characters (such as the *sella turcica*) and adaptive characters (such as the optic specializations). Piveteau's continued study of Primates enables him to reaffirm that cerebralization is a major character of the class.

The selection of topics discussed is an interesting reflexion on present-day trends of thought in vertebrate palæontology. The signal generalization that can be made is that the substantive advances in understanding have all depended on the discovery of critical new field evidence—a lesson that commands reflexion.

R. J. G. Savage

[1] *Trans. Amer. Phil. Soc.*, N.S., 52: *Late Permian Terrestrial Vertebrates, U.S.A. and U.S.S.R.* By Prof. Everett C. Olson. Pp. 224 (21 plates). (Philadelphia: The American Philosophical Society, 1962.)

ADVANCES IN ENTOMOLOGY

Annual Review of Entomology

Vol. 8. Edited by Ray F. Smith, in association with Thomas E. Mittler. Pp. vii+529. (Palo Alto, Calif.: Annual Reviews, Inc., 1963.) 8.50 dollars.

THIS volume, the eighth of the series, is made up from the following papers: insect toxins and venoms (R. L. Beard); autointoxication and some stress phenomena (J. Sternburg); mode of action of carbamates (J. E. Casida); some evolutionary aspects of the insect thorax (R. Matsuda); the phylogeny of the Homoptera (J. W. Evans); insect orientation (R. Jander); soil-inhabiting arthropoda (W. Kühnelt); biological aspects of some phytophagous mites (H. B. Boudreaux); significant developments in European corn borer research (T. A. Brindley and F. F. Dicke); genetics of mosquitoes (G. Davidson and G. F. Mason); trypanosomiasis and the tsetse fly problem in Africa (K. C. Willett); development of systemic insecticides for pests of animals in the United States (R. C. Bushland, R. D. Radeleff; and R. O. Drummond); fumigation of insects (A. B. P. Page, and O. F. Lubatti); factors affecting the use of microbiological pathogens in insect control (J. W. MacBain Cameron); sericulture (T. Yokoyama); mutualism between ants and honeydew-producing Homoptera (M. J. Way); the social biology of ants (E. O. Wilson); arthropod transmission of plant viruses (K. Maramorosch); some new aspects in forest entomology (H. Francke-Grosmann); aphid feeding and nutrition (J. L. Auclair).

The editors' preface mentions two of the problems of such a series: those fields of study in which new knowledge is accumulating so rapidly that "these topics lend themselves to retreatment every several years"; and the particular difficulty of covering the field of insect systematics in reviews. The former is one consequence of the immense volume of new work, most conspicuously in the chemistry of living insects, and in experimental studies of their behaviour. Indeed, each year one puts down this *Annual Review* with a determination to read it carefully and so to become a well-informed general entomologist, and each year goes by without time even to do this. There will soon be need for an abstract of the *Annual Review*.

For various reasons details of systematics are not so palatable in a review as the details of chemistry or physiology. The systematic articles, which the editors say they try so hard to include, are either accounts of systematic methods and techniques, or occasional speculations about the phylogeny of a particular group. In the present volume J. W. Evans's views on the Homoptera may be compared with R. A. Crowson's treatment of the Coleoptera in Volume 5; I wonder if the latter author would agree with the former that Hemiptera are "the most isolated phylogenetically of all orders of insects"?

There is certainly a need for more writing about systematics as a way of looking at insects, rather than as a dry, mechanical system of classification. The editors themselves commend the evolutionary point of view, and suggest that the truest expression of systematics is to contribute to a deeper understanding of insect life. I would go further and says that a durable systematics must be an integration of evidence from all aspects of biology, morphology, physiology and behaviour alike. Reviews in these various fields tend to take their systematics for granted, using names supplied by a specialist systematist. They ought to be balanced by other reviews that use the biological evidence to question the systematics.

The present volume contains several examples of a review that can be read with pleasure for general information, and equally studied in detail as an introduction to its field.

H. Oldroyd

ASSIMILATORY CELLS AND TISSUES IN PLANTS

Das Tropische Parenchym

A: Assimilationsgewebe. Von Prof. Dr. Fritz Jürgen Meyer. (Handbuch der Pflanzenanatomie, Bd. IV, Teil 7 A.) Pp. x+188. (Berlin–Nikolassee: Gebrüder Borntraeger, 1962.) 88 D.M.

ALL students of botany are familiar with the structure of assimilatory tissues and cells in at least a few species of plants. There are, however, many variations in the structure both of the assimilatory tissues and of the cells of which they are composed that are less generally known. Because of this, plant anatomists and those who are concerned with the physiology of photosynthesis will welcome the appearance of a new edition of F. J. Meyer's treatise on the subject. The first edition of Dr. Meyer's book was published in 1923 and constituted a slim volume of 87 pages that formed part of Linsbauer's great work of reference entitled *Handbuch der Pflanzenanatomie*. Since the Second World War the publication of the *Handbuch* has been resumed, and a series of new volumes on various aspects of plant anatomy are being prepared by specialists and edited by Prof. W. Zimmerman (Tübingen) and Prof. P. G. Ozenda (Grenoble). In its new guise the *Handbuch* has become an international encyclopædia of plant anatomy and will include contributions in English and French as well as in German.

In order to bring the subject up to date, Dr. Meyer's volume on assimilatory tissue has now been expanded to 188 pages. In it, after a brief discussion of the meaning of the terms assimilation and assimilatory tissue, the author describes and classifies the various forms assumed by assimilatory cells. This classification is based not only on the shapes of the cells but also on any peculiarities which they may exhibit, such as infoldings or invaginations

of the cell walls. Here it seems strange to find that the well-known assimilatory cells of the Coniferae with finely invaginated walls are not classified as arm-cells, which are described separately. This, however, is only a minor point of criticism, for the classification of cell types seems otherwise to be generally acceptable. After discussing the assimilatory cells themselves the author goes on to describe their organization into tissues and the distribution of the assimilatory tissues within the plant body, and we are also told about the mode of development of assimilatory cells and the secondary changes that they undergo. Part 3 of the book is concerned with the walls of assimilatory cells and in Part 4 we pass on to the cell protoplasts and their inclusions. In Part 5, which concludes the main body of the text, the structure of assimilatory tissues is considered in relation to its physiological function and to the strains and stresses which are imposed on it by the environment. The book concludes with a bibliography occupying 10 pages, the compilation of which was closed in August 1961, and with separate indexes referring respectively to subjects, to the families and genera of plants and to authors.

The book is one for which a place should be found in all botanical reference libraries and in all laboratories where the investigation of plant structure is being actively pursued.

C. R. METCALFE

OXYGENASES

Oxygenases

Edited by Osamu Hayaishi. Pp. xii + 588. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1962). 125*s*.

FIFTY years have elapsed since Sir Frederick Gowland Hopkins, in his address to the British Association at Birmingham, described the life of the cell as "the expression of a particular dynamic equilibrium which obtains in a polyphasic system". As the science of biochemistry has developed since 1913, Hopkins's central idea of a dynamic state of chemical compounds in the living cell has been accepted universally. This conception in turn raised a problem: How may these unceasing biochemical transformations be reconciled with the constancy of pattern which we discern both in the chemical events themselves and in the cellular architecture, complex yet persistent in finest detail? The mechanism, as envisaged by Watson and Crick, by which the intricate molecular designs of proteins are replicated has been the inspiration of a great and increasing sector of biochemical research; and indeed we may need to remind ourselves that there still remain to be investigated many of the enzymes by which, as Hopkins also foresaw in his Birmingham address, all these metabolic reactions are catalysed. This excellent book reminds us that much of one important area of enzymology remains unexplored.

As Osamu Hayaishi remarks in a chapter which surveys the history and scope of the subject, the investigation of biological oxidation was begun by Lavoisier about two hundred years ago. Since that time, it became a firmly accepted principle of biochemistry that oxidations proceed by the removal of hydrogen atoms or electrons which may be transferred from primary substrates through carriers to molecular oxygen: in some instances, oxygen might serve as their direct acceptor, but in all cases the oxygen was converted into water or hydrogen peroxide. However, eight years ago investigations by two groups of workers associated with H. S. Mason and O. Hayaishi respectively proved, by the use of $^{18}O_2$ and $H_2{}^{18}O$, that, in the course of certain oxidations, oxygen was incorporated directly into the substrate molecule and did not act simply as an ultimate electron acceptor. These reactions are catalysed by enzymes to which the name 'oxygenase' has been given. A 'true' oxygenase incorporates two atoms of atmospheric oxygen into one molecule of substrate, as in the conversion of catechol into *cis–cis*-muconic acid; whereas a 'mixed function' oxygenase, or hydroxylase, incorporates one atom of the oxygen molecule into the substrate and requires an electron donor despite the fact that the substrate is oxidized: the second atom of oxygen is reduced to water. Mixed function oxidases that hydroxylate the benzene nucleus are reviewed in an authoritative chapter by Seymour Kaufman.

The work described in this book establishes the significance of various oxygenases in general metabolism. Hayaishi quotes a striking experiment in which he grew *Pseudomonas* with various aromatic compounds as sources of carbon and showed that 4–9 per cent of the oxygen of cell constituents was derived from atmospheric oxygen. One is reminded of the situation concerning carbon dioxide fixation in 1935 when, on the basis of very careful chemical analysis, Werkman and Wood showed that this gas could be fixed by heterotrophic bacteria, whereas it was then generally believed that this type of assimilation was confined to plants and autotrophic bacteria. The principle of heterotrophic utilization of carbon dioxide was not accepted by many biochemists at first, but by the use of isotopes of carbon it has since been proved that ability to fix carbon dioxide is possessed by practically all forms of life.

The methodology of oxygen isotopes is fully described in a chapter by D. Samuel; and it is because of findings made with this valuable technique that we must accept the fact that oxygen can be fixed biologically, despite a reluctance that might stem from our knowledge of biological oxidations built up from investigations spanning a quarter of a century. P. Nicholls considers "peroxidase as an oxygenase" which, apparently, it is not; however, this chapter takes us skilfully through the maze of contradictory findings and theories about peroxidases. One who has not worked in this field is left with the impression that this indeed is the pursuit of truth for its own sake: much has been learned about the pitfalls of enzymology, the interpretation of enzyme kinetic data and the devising of elegant techniques; but it is difficult to assess the physiological significance of peroxidases and the investigation of dihydroxyfumarate oxidase appears to be, in the words of Nicholls "the study of a chemical accident". On the other hand, there is no doubt, when one considers the carbon economy of this planet, about the significance of phenolytic oxygenases discussed by A. Mehler.

Plants lock up carbon atoms in cyclic structures and soil bacteria release them by the action of these enzymes: they are therefore essential for the continuance of life. Until four years ago it was thought that bacteria invariably open the benzene nucleus between adjacent carbon atoms bearing hydroxyl groups. It is now known that this does not always occur and that ring-fission may be catalysed by '2:3-oxygenases' which, while attacking dihydric phenols, open the benzene ring between a carbon atom bearing a hydroxyl group and one that does not. Very recent work at Bangor (Prof. W. C. Evans, private communication) has shown that such enzymes attack condensed aromatic ring compounds, which are discussed by J. W. Foster in a chapter on the bacterial oxidation of hydrocarbons; accordingly it is probable that some of the metabolic schemes presented in this chapter will shortly require modification and extension. Other chapters deal with oxygenases in lipid and steroid metabolism, phenolase, model oxygenase systems, cytochrome oxidase, hæmoglobin and myoglobin, and hæmerythrin and hæmocyanin; they are all written by acknowledged experts in the respective fields and the book is edited by Osamu Hayaishi, whose researches on the oxygenases have led to so much fruitful activity.

This book is a notable contribution to enzymology.

S. DAGLEY

DISTRIBUTIONS OF *n*-PARAFFINS IN CRUDE OILS AND THEIR IMPLICATIONS TO ORIGIN OF PETROLEUM

By RONALD L. MARTIN and JOHN C. WINTERS

Research and Development Department, American Oil Co., Whiting, Indiana

AND

JACK A. WILLIAMS

Pan American Petroleum Research Center, Tulsa, Oklahoma

PETROLEUM is now generally accepted to have been derived from organic remains of plant and animal life deposited with sediments. The types of organic compounds which served as precursors, however, are open to conjecture. Among materials prominently mentioned are fatty acids, alcohols, free hydrocarbons, steroids, isoprenoids of several types, and amino-acids.

Fatty acids have probably received the most support as petroleum precursors[1–3]. This is because they are widely distributed in plants and animals and have structures similar to *n*-paraffins, which are abundant in crude oils. The fatty acids—saturated as well as unsaturated—exist as parts of both fats and waxes. In fats, they occur as triglycerides and generally are unbranched with an even number of carbon atoms between C_{12} and C_{22} (ref. 4). In waxes, they usually exist as simple esters and again are generally unbranched with an even number of carbon atoms; although some have chains under C_{22}, most are generally between C_{24} and C_{36} (ref. 4).

The waxes also contain long-chain alcohols and free hydrocarbons, both of which also are possible petroleum precursors. The alcohols occur both in the free state and as esters with the fatty acids; they generally have straight chains and are monohydric. Alcohols between C_{10} and C_{36} have been identified; the more abundant ones[5] are the even-numbered members of C_{14}–C_{18} and C_{26}–C_{34}. Free hydrocarbons of each carbon number between C_{22} and C_{36} have been found in certain waxes[6]; the members with an odd number of carbon atoms are in the majority.

A likely reaction for fatty acid source materials, among many possible, would have been decarboxylation to give hydrocarbons with an odd number of carbon atoms. If this reaction occurred, it could have left petroleum with an excess of straight-chained compounds with an odd number of carbon atoms. An excess of *n*-paraffins with odd numbers of carbon atoms in the C_{23}–C_{35} range has been found in the organic matter of recent sediments[7], but until now has not been found in crude oils. Previous failures to find any such excesses in crude oils have cast doubts on whether fatty acids acted as petroleum precursors. Theories have been proposed[3], however, to explain how fatty acids could have been source materials without leaving an excess of odd-numbered remnants.

As part of an extensive programme on the analysis of crude oils[8], we began a gas-chromatographic investigation of *n*-paraffin distributions in crude oils. The *n*-paraffin amounts were sought for the clues they might give on petroleum precursors.

Forty crude oils, many selected on the basis of a high *n*-paraffin content, have now been surveyed for *n*-paraffin distributions by gas chromatography. Eight of the more interesting ones have been analysed intensively to obtain accurate values for each *n*-paraffin to C_{35}. Some crude oils show 'predominances' of certain odd-numbered members; that is, they contain at least several per cent more of these than would be predicted from the amounts of the neighbouring even-numbered *n*-paraffins. The major such predominances are between C_{11} and C_{19}. Those between C_{21} and C_{35}, where much of the previous searching has been concentrated[7], are smaller and less frequent.

Several different analytical techniques were used for determining distributions of *n*-paraffins. Initially, the 40 crudes were run on a packed gas-chromatographic column with temperature programming. Eight of the more interesting of these were then examined by one or both of two other techniques to obtain a more precise determination of the *n*-paraffins. In the first technique, paraffins were concentrated by removing sulphonatable components (for example, aromatics) by reacting the whole crude oil with sulphuric acid; the paraffin concentrates were then run on a temperature-programmed capillary column of high efficiency. This approach gave a better resolution of *n*-paraffins from the background of other peaks and was especially useful between C_8 and C_{18}. In the second technique, *n*-paraffins above C_{15} were removed essentially quantitatively from the crudes by adduction with urea[9]; the *n*-paraffin concentrates, which contained only small amounts of interfering compounds, were then analysed by gas chromatography on the packed column with temperature programming. Analyses for *n*-paraffins to C_{35} were obtained by comparing results from these three types of runs. Uncertainties in the analyses should be no greater than 7 per cent of the amounts found or 0·02 per cent, whichever is larger.

In the programmed-temperature runs on whole crude, about 90 per cent of the samples gave *n*-paraffin peaks which clearly projected above the background of other peaks and were measurable semi-quantitatively. In these, the range and maximum of the distributions of *n*-paraffins could be determined, and any significant predominance of odd-numbered members could be detected.

The packed-column temperature-programmed runs were made on a column, 6 m × 3 mm, containing 10 per cent '*SE*-30' silicone rubber (General Electric Co.) on 'Chromosorb-*P*. The temperature was started at 60° C and programmed at 4°/min to 400°. Detection was by thermal conductivity or hydrogen flame ionization.

Distributions of *n*-paraffins in the 40 crude oils varied considerably. Typically, the *n*-paraffins comprised 15–20 per cent of the total crude. In four crude oils, however, *n*-paraffins above C_7 were barely detectable. In four others, the members through C_{35} comprised more than 30 per cent of the total crude. When *n*-paraffins were measurable, they were present throughout the entire range to C_{35}. In many crudes, however, they were nearing extinction at C_{35}. The maximum concentrations usually were at C_6 or C_7, but sometimes occurred as low as C_4, and in one case as high as C_{27}.

A predominance of certain odd-numbered *n*-paraffins was detectable in 14 of the 40 crude oils. It was clearly evident in seven of the fourteen. It was only slightly above the detectable limit in the other seven. A predominance was detectable when an *n*-paraffin was 3–7 per cent higher than would be predicted from the sizes of the neighbouring *n*-paraffins.

Table 1. Normal Paraffins in Eight Crude Oils
(% by volume)

Table 2. Description of Crude Oils

Field	Location	Gravity (°API)	Producing formation		
			Name	Era	Age
John Creek	Morris Co., Kansas	26·6	Viola	Palæozoic	Ordovician
Kawkawlin	Bay Co., Michigan	35·0	Dundee	Palæozoic	Devonian
Pine Unit	Wibaux Co., Montana	31·9	Red River	Palæozoic	Ordovician
Ponca City	Kay Co., Oklahoma	42·0	Simpson	Palæozoic	Ordovician
Uinta Basin (field unnamed)	Uintah Co., Utah	30·6	Green River	Cainozoic	Tertiary (Eocene)
Darius	Persian Gulf	29·0	Yamama	Mesozoic	Cretaceous
North Smyer	Hockley Co., Texas	43·2	Strawn	Palæozoic	Pennsylvanian
State Line	Sweetwater Co., Wyoming	39·4	Fort Union	Cainozoic	Tertiary (Palæocene)

Distributions of *n*-paraffins for the eight intensively analysed crudes are given in Table 1. Five of them—John Creek, Kawkawlin, Pine Unit, Ponca City, and Uinta Basin—show predominances of certain odd-numbered *n*-paraffins. The three others with little or no predominances—Darius, North Smyer, and State Line—are included for comparison. Table 2 gives field location, age and name of producing formation, and American Petroleum Institute (API) gravity for the eight crude oils.

The *n*-paraffin distributions in four of the crude oils are shown in Fig. 1; three different types of distributions are illustrated. John Creek and Pine Unit show large predominances of odd-numbered members between C_{11} and C_{19}. Uinta Basin shows small odd-numbered predominances and a high proportion of *n*-paraffins in the C_{20}'s and C_{30}'s. Darius shows a 'typical' distribution.

Three crudes—John Creek and Pine Unit (Fig. 1), and Kawkawlin—have similar and strikingly large odd-numbered predominances. All have significantly more of the C_{11}, C_{13}, C_{15}, C_{17}, and C_{19} members than would be predicted from the amounts of the neighbouring even-numbered members. Also, the *n*-paraffins in each show a maximum at C_{11} and a sharp drop around C_{18}. Small differences exist, however, in the degree of the predominances at the different carbon numbers. Unlike the other two, Pine Unit shows only a very slight predominance at C_{15}. Pine Unit and Kawkawlin show their largest predominances at C_{11}; John Creek has its largest at C_{17}.

Ponca City also shows some similarities to John Creek, Kawkawlin, and Pine Unit—with predominances at C_{13}, C_{15}, C_{17}, and C_{19} and a drop around C_{18}. The odd-numbered predominances, however, are smaller and the drop around C_{18} is less sharp.

Strikingly, all four of these crudes are produced from early Palæozoic formations, which are the oldest normally yielding petroleum. Moreover, of the crude oils surveyed, essentially all of this age show detectable predominances of this sort, whereas none of younger age shows more than a suggestion of such predominances. Examples of other crude oils with predominances between C_{11} and C_{19}, are: Davis Ranch (Wabaunsee Co., Kansas), Eola McLish and Eola Oil Creek (Garvin Co., Oklahoma), Glendive (Dawson Co., Montana), Redwater (Alberta, Canada), and Teas (Garza Co., Texas). All these are from Ordovician formations except Redwater, which is from Devonian. Predominances in Davis Ranch and Glendive are large and somewhat similar to those in John Creek, Kawkawlin, and Pine Unit. No crudes from Cambrian or Silurian formations were analysed.

The distribution of *n*-paraffins in the Eocene-Age Uinta Basin crude is much different from that in the Ordovician and Devonian crudes. The proportion of *n*-paraffins in the C_{20}'s and C_{30}'s is significantly greater than in any other crude analysed; the largest member is C_{27}. Except for C_{17}, there is little or no predominance of any *n*-paraffin below C_{21}; however, from C_{23} to at least C_{33}, there is a small predominance of the odd-numbered members, each of which is a few hundredths of a per cent higher than would be indicated from the even-numbered members. *n*-Paraffins in Uinta Basin appear to be in two groups, one with a maximum at about C_9 and the other with a maximum at about C_{27}.

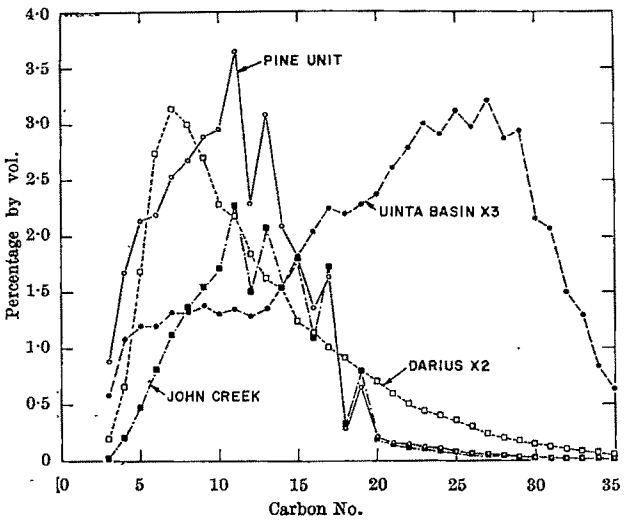

Fig. 1. Distributions of *n*-paraffins in four crude oils

Although Darius, North Smyer, and State Line possess little or no predominances, they again illustrate different *n*-paraffin distributions. The *n*-paraffins in Darius illustrate a 'typical' distribution—no significant predominances, a maximum at C_7, and no sharp drop around C_{18}. North Smyer shows a steady decrease of *n*-paraffins from C_4 to C_{35}. State Line, on the other hand, has an unusually high proportion of *n*-paraffins in the higher carbon numbers, with a maximum at about C_{17}; it gives indications of possessing small odd-numbered predominances in the C_{20}'s.

Two of the crude oils in Fig. 1—Uinta Basin and Pine Unit—show indications of slight odd-numbered predominances between C_5 and C_9. Unfortunately, these predominances, if real, are too small to be identified with certainty.

Implications of Results to Origin of Petroleum

The strikingly high proportions of *n*-paraffins in crude oils, typically 15–20 per cent and sometimes more than 30 per cent, suggest straight-chain compounds as an important type of petroleum source material. Such facts, among others, have led other investigators[1–3] to postulate fatty acids as principal petroleum precursors. Our findings of predominances of odd-numbered *n*-paraffins between C_{11} and C_{19} support this idea.

John Creek, Kawkawlin, Pine Unit, and Ponca City were probably derived from source materials rich in fatty acids from naturally occurring fats. The C_{11}–C_{19} predominances match well with the usual carbon range of the fatty acids in fats, which is C_{12}–C_{22}. Simple decarboxylation, by one means or another, would yield compounds of the correct chain-length. Alcohols—some of which exist naturally with chains of C_{12}–C_{20}—possibly could have caused the C_{11}–C_{19} predominances, but they would have had to lose a carbon atom along with the hydroxyl group. Waxes, which generally contain chains of C_{24}–C_{36}, are not indicated as principal source materials for these four crudes.

In contrast, Uinta Basin crude, with odd-numbered predominances and a large proportion of *n*-paraffins between C_{23} and C_{33}, could well have been derived from source materials rich in waxes. The odd-numbered predominances approximate the range of carbon chain-lengths in naturally occurring waxes. This proposed wax derivation agrees with its supposed non-marine origin; waxes in the C_{22}–C_{36} range are more prevalent in terrestrial life than in marine life[10]. The State Line crude also could have been derived from a source material rich in waxes. It also is believed to be of non-marine origin.

Most of the crudes observed to have high proportions of *n*-paraffins in the C_{20}'s and C_{30}'s, like Uinta Basin and State Line, have been of Cainozoic age. This could be a result of a larger proportion of plants having high wax contents in this era than in the earlier eras[10]. Waxes are normally most abundant in the cuticles of leaves, petals, and fruit coatings; they would probably be supplied in greater quantity by the flowering plants dominating the Cainozoic Era than by the fern and related plants prominent during the late Palæozoic and early Mesozoic Eras.

The odd-numbered predominances between C_{23} and C_{33} in Uinta Basin crude may indicate derivation from fatty acids, alcohols, or free hydrocarbons—all of which occur in waxes. Fatty acids might be the most logical guess. The alcohols, most of which are even numbered as they exist naturally, would have had to lose a carbon atom along with a hydroxyl group. The naturally occurring free hydrocarbons are mainly odd numbered, and, although present only in very small amounts, also are a possibility[11].

Even if C_{12}–C_{20} fatty acids were accepted as important source materials for the Ordovician and Devonian crudes, several puzzling questions remain:

(1) Why are the predominances at C_{11} and C_{13} so large, when the C_{12} and C_{14} acids typically comprise only 5–10 per cent of the fatty acids in naturally occurring fats? Most of the fatty acids are generally C_{18} and C_{16}.

(2) Why do most crude oils not possess odd-numbered predominances, and not show a sharp drop in *n*-paraffins around C_{18}?

(3) Why do the crudes showing odd-numbered predominances between C_{11} and C_{19} come only from early Palæozoic formations?

The strong odd-numbered predominances at C_{11} and C_{13} seem explainable, if all the predominances are assumed to have resulted entirely from *saturated* fatty acids. Naturally occurring saturated acids, unlike unsaturated ones, are not concentrated so heavily at C_{18} and C_{16}. For example, the overall proportions of saturated acids among total fatty acids in world-wide vegetable fats[4] are: C_{12} (7 per cent), C_{14} (3 per cent), C_{16} (11 per cent), C_{18} (3 per cent), and C_{20} (< 3 per cent). Although the fats in the simple animals and plants of the Palæozoic Era may not have been identical to present-day vegetable fats, the example illustrates that naturally occurring saturated acids can exist relatively evenly dispersed between C_{12} and C_{20}. It is unlikely that unsaturated acids could have been dispersed in this manner, because the C_{12} and C_{14} unsaturated acids are not major constituents of natural fats[4].

Most of the crude oils examined did not show odd-numbered predominances or a sharp drop around C_{18}; a possible explanation follows from the assumption that the predominances where present came from saturated acids. *Unsaturated* acids, it seems to us, could have been the principal source materials for most crudes, especially those younger than Devonian. The unsaturated acids, or perhaps their olefinic remnants, would have been more prone to other reactions[1], including polymerization, than the saturated acids. Extensive polymerization followed by random cracking[2] could have yielded a smooth distribution of *n*-paraffins with no sharp drop after C_{18}, even if the source acids were mainly C_{18} and C_{16}.

The sharp drops after C_{18} with John Creek, Kawkawlin, and Pine Unit suggest, of course, that very little polymerization occurred with these crudes. Cracking reactions also must have been relatively small, because the maxima of the *n*-paraffin distributions are at C_{11}, rather than at the more usual C_6 or C_7. With only slight polymerization, less cracking would be expected, because the smaller molecules would be thermodynamically more difficult to crack.

The usual lack of both odd-numbered predominances and a sharp drop after C_{18} also could be explained by

source materials with carbon chains above C_{18}. For example, extensive cracking of source materials principally of C_{24}–C_{36} could have yielded the observed distributions. Such an explanation, however, would require an abrupt change in principal source material after the Devonian age, where the source material appears to have been principally in the C_{12}–C_{20} range.

The explanation for finding C_{11}–C_{19} predominances only in crude oils from early Palæozoic formations is even more conjectural. Some of the arguments have already been introduced. The first, of course, would be that higher proportions of saturated acids were produced by the plants and animals in that age. This is a possibility, because uniformly warm climates are believed to have prevailed during most of the early Palæozoic Era[12], and living forms in warm climates tend to produce a higher proportion of saturated acids[4]. For example, in those plants which thrive in both hot and cold climates, higher proportions of saturated acids are produced in the hot climates[4]. As further support for saturated acids, Breger[1] has proposed the theory that the paraffinic character of old oils may be a consequence of a higher proportion of saturated lipids in their source materials.

The fact that C_{11}–C_{19} predominances were found only in early Palæozoic crude oils also could be a consequence of simpler forms of life present during that time[10]. The proportion of animal life possibly was higher then. Plant life apparently increased both in amount and complexity during the Devonian age[10]. Crude oils younger than Devonian, then, could have had higher proportions of source materials other than fatty acids; these other materials might have yielded a majority of the *n*-paraffins. Other evidence for a greater proportion of fatty acids in the source material for Palæozoic crude oils comes from carbon-isotope ratios. Lower values of $^{13}C/^{12}C$ are found in early Palæozoic crude oils than in most younger crudes[13,14]. This has been interpreted to indicate a relatively greater contribution from the lipid fraction, which has a lower value for $^{13}C/^{12}C$ than that from the whole plant or animal[13].

DUPLEX ORIGIN OF PETROLEUM

By Sir ROBERT ROBINSON, O.M., F.R.S.

Emeritus Professor of Chemistry, University of Oxford : Past-President of the Royal Society

RECENT contributions bearing on theories of the origin of petroleum have considered the problems from the geological point of view, naturally including some of the geochemical aspects associated with questions of distribution. The organic chemical arguments derived from an investigation of the composition of petroleum (also natural gas, waxes, and bitumens) have been neglected or slurred over, the serious difficulties being set aside for later resolution.

An examination of the available evidence convinced me that petroleum hydrocarbons are both biogenic and abiogenic, the latter portion being very much the older, probably by a factor of 4 or 5 times the maximum hitherto contemplated for biogenic petroleum. These views have been expounded in lectures in many centres from 1961 to the present year—Delhi, Milan, Glasgow, Manchester, Bonn, Oxford, Aerojet Research Laboratory (California), Johannesburg, Westchester Chemical Society (Tarrytown, New York), Dublin and again at Milan. An abstract of the paper to the symposium at Bonn was published[2].

The chief points are the following:

(*a*) The evidence for the biogenesis of petroleum is incontrovertible; but this may only apply to a part of the material. The indications of biogenesis are clear in young oils, less in evidence in those of middle age, and all but absent in the older crudes[3]. They do not completely disappear in any of the crudes yet examined with sufficient care.

(*b*) The adherents of 100 per cent biogenesis assume that the organic matter laid down in the sediments could be modified at quite moderate temperatures and pressures in the course of ages until it became the ancient petroleum which we describe as a 'crude' oil. The apology for the improbabilities that have to be accepted is the large time-scale involved, perhaps 400–500 million years. It is the inverse of the 'housemaid's baby' plea and equally unconvincing. Actually it cannot be too strongly emphasized that petroleum does not present the composition picture expected of modified biogenic products and all the arguments from the constituents of ancient oils fit equally well, or better, with the conception of a primordial hydrocarbon mixture to which bio-products have been added.

(*c*) Improvements in chromatographic analysis and other new resources, such as separation of normal hydrocarbons as complexes with urea, have given us a much more complete knowledge of the constituents of petroleum in the lower ranges[4]. It emerges that the straight-chain hydrocarbons always predominate over any one of the branch-chain isomers, though the latter in total in each carbon-number exceed 50 per cent of the hydrocarbons having a carbon number of 6 or more. In the ancient petroleums (including natural gas) the percentage of the whole drops steeply from methane to pentane and then gradually through all the carbon numbers examined. There are a few weak peaks of occurrence at odd carbon numbers, but the alternation in the occurrence of hydrocarbons as we pass up the series is almost absent. Such alternation is perhaps the most characteristic proof of biogenesis in oils from recent sediments.

(*d*) An examination of the nature of branch-chain hydrocarbons in the smaller carbon numbers (C_5–C_8) and of their quantitative relation to the corresponding *n*-alkane suggests that the branch-chain hydrocarbons could have been derived by isomerization processes. These have apparently been accompanied by *cyclo*dehydrogenation, for example, *n*-hexane to 2-methylpentane and methyl*cyclo*pentane, *n*-heptane to 2- and 3-methylhexane, methyl*cyclo*hexane and then to dimethyl*cyclo*pentane.

(*e*) Certain minor constituents are best regarded as the outcome of synthesis. For example, adamantane is most plausibly postulated as arising from *cyclo*pentadiene by dimerization, reduction and then pyrolysis[5].

(*f*) The absence of oxygenated compounds and of olefines is indicative of a hydroforming type of operation. Aromatic hydrocarbons, thiophenes, and pyridines survive because of their relative high degree of resistance to hydrogenation.

(*g*) Crude petroleum is similar to the mixture which could be expected as the result of hydroforming of Fischer–Tropsch hydrocarbons. As an alternative to the Fischer–Tropsch synthesis of the primordial oil, the action of radiation on methane (with formation of carbene) may be considered. This would furnish straight-chain hydrocarbons, but the ingenious theory of A. T. Wilson[1] using methyl radicals and terminal attack of crowded chains is rather improbable, and could be submitted to test by experiment.

(*h*) It is supposed that the primordial oil (perhaps ± 2,000 million years ago, and later up to the deposition of the sediments) was used as a source of carbon by primitive organisms. These contributed components to the oil and, later, phytoplankton and land plants did likewise. It can easily be understood that the picture is blurred, and that its original component parts are difficult to recognize in even semi-quantitative detail at the present time.

We start with a synthetic mixture of hydrocarbons which may be assumed to be essentially a series of *n*-alkanes. This was submitted to thermal and possibly catalytic reforming under reducing conditions. Such processes may have been effective more than once, for example, both before and after the incorporation of biological material. At certain stages cracking to lower hydrocarbons (perhaps olefines) and synthesis appear to have occurred and it is noteworthy that the postulated constituents from bio-sources must also have encountered strong reducing conditions. After the association with bio-activities the material was distributed and may well have been separated in various ways, two of which are solution and deposition in water, and clathrate filtration through sediments or porous rocks.

The branched and *n*-alkanes in the C_5, C_6 and C_7 groups (beyond C_7 our information is still insufficient) are not present in the proportions required by attainment of full thermal equilibrium under conditions so far examined. However, we are not dealing with a pure substance, and cross-reactions between the molecules not only might, but probably would, affect the outcome.

As an example of the type of difficulty encountered in attempting an analysis of the data it may be mentioned that the content of 2-methylpentane is greater than that of 3-methylpentane[4]. This is the anticipated result of isomerization of *n*-hexane. On the other hand, the content of 3-methylhexane is usually a little greater than that of 2-methylhexane, and there must be some special reason for this apparent anomaly. It is not at all difficult to devise explanations for these and other similar findings, but it is scarcely worth while to discuss the alternatives, especially as this aspect of the problem is not beyond the reach of experimental investigation.

Addendum. Since submitting this article, I have been afforded the opportunity to read the preceding article by R. H. Martin, J. C. Winters and J. A. Williams in advance of publication. It is a contribution of outstanding value and, as the authors indicate, the new information raises fresh problems, the solution of which cannot be obtained on inspection.

Full comment must be reserved; but some general remarks may be made.

The authors start by noting that the biogenic theory is now generally accepted. They proceed to attempt to explain their results in terms of this (100 per cent) hypothesis. Actually, however, the striking and novel observation of odd predominance in crude oils from palæozoic formations refers to the minority of the petroleum examined.

The authors' puzzling question (2) should perhaps be re-phrased so as to ask for an explanation of these exceptional cases.

The remarkable differences found for the first time in the *n*-alkane distribution in ancient crude oils are, it seems, to be related to changes in the source organisms or their biochemistry. They are at last equally consistent with the duplex origin of petroleum which, indeed, could be expected to lead to such divergencies. Finally, the authors' suggestion of a decarboxylation mechanism is not strongly supported by what is known of the metabolism of fatty acids. If it occurred as a major process in the formation of *n*-alkanes in the remote past there should surely be some evidence of its importance at the present time. For example, *n*-pentadecane and *n*-heptadecane should be found in quantity in some plant or animal.

CHEMICAL ALTERATION OF URINE

By Prof. R. B. GRIEVES and Prof. J. E. QUON
Technological Institute, Northwestern University, Evanston, Illinois

RE-USE and reclamation of water have been widely practised in industry and irrigation. The need is a result of a limited number of easily accessible and suitable sources. Water recovery systems for manned-space flights have received considerable attention. This type of need also exists in community fall-out shelters. Re-use and reclamation of water in the latter two cases need not be restricted to recovery of potable water. Uses of water necessary for maintaining proper hygienic conditions include bathing and laundry, and as a waste disposal medium.

The quality requirements of a water supply depend on the usage or function for which the supply is intended. High-pressure boiler water has a low tolerance for inorganic scale-forming impurities; characteristics of potable water may vary over a considerable range, but rigid standards for specific chemicals or pathogenic organisms are desirable (it is to be noted that distilled water is not the optimal potable water); water used for agricultural purposes may impose unique limitations, for example, boron.

One possible method of purification of urine which requires no external source of power is the alteration of urine by purely chemical means. Most of the research in purification of urine has aimed at producing a potable water and has utilized techniques such as distillation and vacuum distillation followed by vapour pyrolysis, zone refining, freeze-drying, electrodialysis, etc.[1–4]. Physico-chemical treatments have been utilized only as secondary processes following an initial step such as distillation. The relative advantage of a given process depends on the characteristics of the feed, the desired quality of the effluent, the amount of power available, and the absence of nuisance conditions. The reclamation of water from

urine by distillation or any process requiring heat causes the liberation of volatile compounds not originally present and which are highly odoriferous. In certain cases, such as community fall-out shelters, it may therefore be undesirable to produce a water from human urine by processes requiring heat.

The chemical and physical characteristics of urine vary with the diet of the individual and the length of time elapsed between excretion and analysis. For example, the excretion of urea ranges from 4·7 g/day for persons on a low-protein diet to 31·5 g/day for persons on a high-protein diet[5]; ammonia may be present in large amounts as a result of the decomposition of urea. A number of authors present urine analyses[6]. Any listing of the constituents is necessarily incomplete because of the presence of many trace compounds and the difficulties associated with microanalysis for these compounds. The two gross constituents are urea and sodium chloride. Other materials which are excreted in amounts greater than 1 g/day are creatinine, potassium, phosphates and sulphates.

Craig[1] reports on operationally distilling urine for a drinking water supply. Investigations were also made on the distillation of urine by Ingram *et al.*[7]. Konecci and Wood[2] outlined a urine-distillation unit capable of distilling 20 lb. of water a day and requiring 300 W of power; the urine is centrifuged and heated; the vapour then passes through an activated charcoal filter and condenses on a 40° F condenser panel; the condensed water is then passed through another charcoal filter; a second distillation may be desirable. Golueke *et al.*[8], in discussing distillation, point out that a large amount of heat is required, and toxic fumes, particularly ammonia, are present.

Sendroy and Collison[3] and Bambenek and Zeff[9] mention freeze-drying as another means of purification. This consists of freezing urine, subliming the ice at 0·11–0·15 mm pressure, and then collecting the vapour.

The two processes of distillation and freeze-drying have proved workable; however, they do have some shortcomings. One of the main problems associated with distillation is the thermal breakdown of the compounds in urine which produces toxic or obnoxious fumes. Ingram[7] points out that the distillate from a distillation process will require additional treatment to remove carry-over taste and odour-producing compounds. Konecci and Wood[2] also allude to this possibility. Both the freeze-drying and distillation processes need fairly complex equipment. This is especially true of the former method because of the high vacuum needed. The power requirements of both processes may be disadvantageous in certain cases.

One of the possible methods of urine purification which requires no external source of power is the alteration of urine by purely chemical means. Chemical oxidation followed by ion exchange has the potential of producing a usable water from urine. Urea is the major component present in urine, and the successful removal of the former would provide the essential initial step in any scheme for chemical alteration. Two possible oxidizing agents would be nitrous acid and calcium hypochlorite. The nitrous acid scheme is attractive since the reaction products would be carbon dioxide, nitrogen, and water; thus, apparently no additional ions would have been added to the treated urine. Precipitation of urea as urea nitrate and hydrolysis of urea by urease are other possible methods of removal of urea from urine. For the removal of objectionable inorganic and certain ionizable organic molecules, the technique of ion exchange demineralization could be used. The sequence of a base exchange resin followed by an acid exchange resin would be advantageous from the point of view of utilization of the maximum exchange capacities of the resins.

This investigation attempted to explore the feasibility of removal of urea followed by ion exchange, using chemical and physical tests as criteria of water quality. Oxidation of urea by nitrous acid and calcium hypochlorite, precipitation of urea by nitric acid, and hydrolysis of urea by urease were examined under ambient conditions (24° C and 760 mm mercury). The exchange capacities of two commercial resins operating on an acid-base cycle were determined using raw urine as the feed. Analyses were made on the feed and effluents from the exchange columns for total solids, for *p*H, for colour, and for the ionic concentrations of sodium, potassium, calcium, chloride, and sulphate.

Reaction of Urea. The schemes for urea removal were suggested by available methods for the analytical determination of urea in urine. The oxidation of urea by nitrous acid giving water, nitrogen, and carbon dioxide as end-products is attractive if the urine is to be treated afterwards by ion exchange. Unfortunately, nitrous acid is known only in solution, and must be prepared as needed by the reaction of ammonia and hydrogen peroxide, sodium nitrite and sulphuric acid, or similar schemes. Urea concentrations in aqueous solution and in urine were determined with the Mclean ureometer[10]. As with many reactions involving organic compounds, the oxidation of urea does not proceed quantitatively as outlined by the stoichiometric equation. Approximately twice the stoichiometric amount of nitrous acid (63 g/l.) was necessary for the oxidation of urea in aqueous solution (24 g/l.) and in urine.

The result of using calcium hypochlorite, a stronger oxidizing agent than nitrous acid, is shown in Fig. 1.

$$3\,Ca(OCl)_2 + 2CO(NH_2)_2 = 3CaCl_2 + 2CO_2 + 2N_2 + 4H_2O \quad (1)$$

Approximately 120 per cent of the stoichiometric amount of calcium hypochlorite (144 g HTH, 65 per cent available chlorine) is required for the oxidation of urea in aqueous solution (20 g/l.).

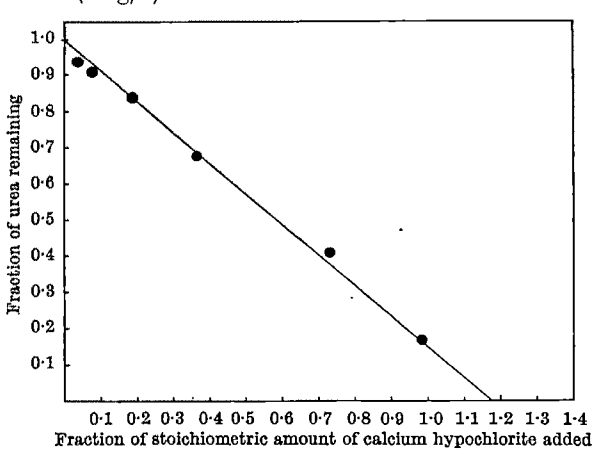

Fig. 1. Oxidation of urea solution by calcium hypochlorite. Initial urea concentration, 20·0 g/l.

The possibility of precipitating urea as urea nitrate may be dismissed because of its relatively high solubility in aqueous solution.

The hydrolysis of urea by the enzyme urease is most rapid when the solution is buffered at a *p*H of 7 and the concentration of urea is in the order of magnitude of 1–2 g/l.[11]. The dependence of hydrolysis of a high concentration of urea (20 g/l.) as a function of urease concentration, under ambient temperature and with the solution not buffered with respect to *p*H, is shown in Table 1. A 90 per cent hydrolysis of urea in 24 h was observed for urease concentrations ⩾ 2 g/l.

Table 1. HYDROLYSIS OF UREA BY UREASE UREA CONCENTRATION: 20 GM./L.

Urease concentration (g/l.)	% Urea hydrolysed
1·0	72
2·0	92
6·0	88
10·0	90

The most promising method of urea removal appears to be the use of calcium hypochlorite. The reaction products are nitrogen, carbon dioxide, water and calcium chloride. However, precipitation of calcium and chloride ions in solution resulting from the oxidation step can be effected if ion exchange is to follow. Approximately 24 per cent of the calcium content of the calcium hypochlorite added was precipitated accompanying the oxidation reaction; the introduction of silver and carbonate ions into a solution containing calcium and chloride ions seemed likely to precipitate silver chloride and calcium carbonate, since the solubility products of these compounds are quite low. Four precipitation methods were evaluated: (1) use of a saturated solution of silver carbonate in ammonium hydroxide; (2) use of dry silver carbonate; (3) use of silver carbonate followed by silver oxide; (4) use of dry silver oxide.

The complete removal of both calcium and chloride ions was effected by the procedures of methods 1 and 2, using the stoichiometric quantity of silver carbonate based on chloride content. Analysis showed that addition of silver carbonate beyond the requirement for complete precipitation of calcium continued to precipitate chloride, but introduced undesirable carbonate ions into solution. A two-stage precipitation was attempted (method 3) using the stoichiometric quantity of silver carbonate based on the calcium content and 130 per cent of the stoichiometric quantity of silver oxide based on the remaining chloride content. Complete removal of both calcium and chloride ions was effected by the precipitation and filtration steps. Silver oxide increases the alkalinity of an aqueous solution through hydrolysis, and reaction of dissolved carbon dioxide with the alkalinity produces carbonate ions. Approximately 130 per cent of the stoichiometric quantity of silver oxide (based on chloride content) was contacted with a urea solution (method 4) following the oxidation step. Again, complete precipitation of both calcium and chloride ions was effected. For a 24 g/l. urea solution method 3 required 160 g/l. of calcium hypochlorite, 180 g/l. of silver carbonate, and 82 g/l. of silver oxide; method 4 required 160 g/l. of calcium hypochlorite and 306 g/l. of silver oxide.

Ion Exchange. The utilization of ion exchange as a method of treating urine has been explored to a very limited extent. Bonting[12] made use of ion exchange resins in a laboratory analysis of urine. He established the total cation content of urine by removing all the cations with a small ion exchange column and by determining the quantity of hydrogen ions in the effluent. He reported that better than 99 per cent removal was achieved from contacting 0·7 mequiv. of cations with the exchange resin; he did not consider the capacity of the resin. McNeil[13] attempted to develop a method of waste disposal in aircraft by passing urine through a combined anion-cation exchanger and then by permitting the effluent to be picked up by a large wick for evaporation into a warm air stream. It was found that the resins were exhausted after the passage of 400 ml. of urine. A few additional references have been made in the literature to the use of ion exchange as a final purification technique following distillation or freeze-drying.

Although ion exchange would be best utilized as a secondary treatment process, following initial urea removal and precipitation, it is not unreasonable to assume that ion exchange could be the initial step in a urine purification process, particularly if some urea could be exchanged. 'Amberlite *IRA* 402', a quaternized chloromethylated polystyrene (strongly basic), was chosen as the anion exchanger, and 'Amberlite *IRC* 50', a poly (methacrylic acid) (weakly acidic) was chosen as the cation exchanger.

Two cylindrical glass columns, 24 in. long with an inside diameter of 1⅞ in. and containing 330 g dry resin, were operated in series. Untreated urine was passed through the column containing '*IRA* 402' (anion exchanger) and the effluent from the anion exchanger was passed through

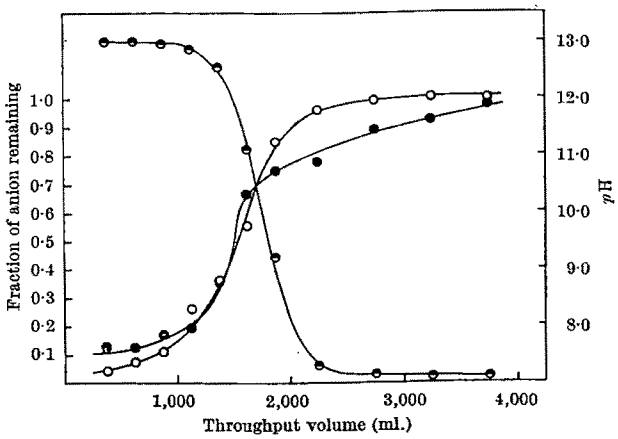

Fig. 2. Variation in chloride, sulphate, and *p*H of effluent from anion exchanger. ○, chloride; ●, sulphate; ◓, *p*H

'*IRC* 50' (cation exchanger). This order was adopted so as to provide an influent to the '*IRC* 50' with a high *p*H. The urine was collected from six male adults over a period of several days and was stored at a temperature of 1°–4° C. During the storage periods there were no signs of degradation; the colour, odour, and *p*H remained unchanged. The effluents were generally collected in 250 ml. batches and were kept refrigerated. Analyses were carried out to determine the average characteristics of the influent to the anion exchanger and of the influent to the cation exchanger. Similar tests were applied to a series of effluent samples from each column. Analyses were made for hydrogen ion concentration, absorptivity at 430 mμ, chloride, sulphate, calcium, sodium, potassium, total solids, and urea.

The zero point of the colorimeter was set with distilled water, and the absorptivity measurements were converted to colour units by comparison with standard solutions containing potassium chloroplatinate and cobaltous chloride[14]. Total solids were determined by evaporation of the samples to dryness at 103°–105° C. Sulphate ion was analysed by precipitation with barium chloride, followed by ignition of the filter residue at 800° C. Chloride was determined volumetrically using silver nitrate and potassium dichromate, and sodium and potassium ion concentrations were measured with a flame photometer. Calcium was analysed by a modification of the standard permanganate test and by the ethylene-diamine tetraacetic acid titration method[14]. An analysis of untreated urine is presented in Table 2. This represents

Table 2. Analysis of Untreated Urine

Test	Results
*p*H	6·6
Colour	1,143 units
Chloride	6·8 g/l.
Sulphate	2·5 g/l.
Calcium	0·15 g/l.
Sodium	3·7 g/l.
Potassium	3·3 g/l.
Total solids	37·6 g/l.

Table 3. Analysis of Influent to Cation Exchanger

Test	Results
*p*H	12·6
Colour	90·0 units
Chloride	1·0 g/l.
Sulphate	0·5 g/l.
Calcium	0·0 g/l.
Sodium	3·7 g/l.
Potassium	3·3 g/l.
Total solids	28·4 g/l.

Table 4. Analysis for *p*H, Sodium, and Potassium of Effluent from Cation Exchanger

Throughput volume (ml.)	*p*H	Sodium (g/l.)	Potassium (g/l.)
Influent	12·6	3·7	3·3
125	3·4	1·0	0·95
625	3·4	0·8	0·7
2,125	4·0	0·55	0·8
4,125	5·0	0·55	0·8
4,625	10·4	0·75	1·8
4,700	11·9	1·2	2·1

the average composition of the influent to the anion exchange column. Analysis of the influent to the cation exchanger is shown in Table 3. The total absence of calcium ion should be noted. It is likely that the calcium was precipitated out in the anion exchanger as calcium phosphate; this was enhanced by the elevated *p*H at which the anion exchanger operated. Although no quantitative analysis was made for magnesium, it seems probable that this cation was also precipitated out as magnesium hydroxide; this was qualitatively determined from the permanganate calcium analysis.

The results for the exchangers are presented in Fig. 2 and Table 4. A break occurred in the effectiveness of the anion exchange resin corresponding to 1,700 ml. of throughput volume, as may be observed from the *p*H and chloride values. Sulphate was still being removed until 2,500 ml. of effluent had been collected. Only the effluent from the anion exchanger prior to the break was fed to the cation exchanger. 5,100 ml. of effluent were collected from three anion columns and were passed through the cation column. It may be observed that the cation column was operating effectively up to 4,700 ml. of throughput volume.

The anion exchanger removed approximately 260 m.equiv. of chloride and 80 m.equiv. of sulphate before the resin was exhausted. This corresponds to 1·03 m.equiv. per gram of dry resin. Four ml. of effluent per cm^3 of resin were collected before exhaustion. In addition, significant quantities of calcium and magnesium were removed, apparently by precipitation; this may have influenced the rapid exhaustion of the anion exchanger by forming a film to block available exchange sites. The cation exchanger removed approximately 500 m.equiv. of sodium and 250 m.equiv. of potassium before the resin was exhausted. This corresponds to 2·27 m.equiv. per gram of dry resin. Eleven ml. of effluent per cm^3 of resin were collected before exhaustion. The combination of both columns reduced the total solids content by 73 per cent. The total solids removal was greater than would be expected from the sulphate, chloride, sodium, and potassium analyses. This may be attributed to exchange of other ions and the filtering action of the exchange beds. Colour reduction by the anion exchanger is shown in Fig. 3; the colour of the effluent was 40 units compared with 1,143 units for the influent. Removal of urea was negligible.

Some success was achieved in the ion exchange studies, from the point of view of producing a usable water. Obviously the greatest disadvantage of such a process is the large quantity of ion exchange resins needed to treat a given quantity of water. Chemical pretreatment of the urine to reduce the ionic load greatly increases the volume of urine treated per cm^3 resin. Better results may conceivably be obtained by using other exchange resins, by reversing the anion and cation columns, or by the use of a mixed ion exchange bed.

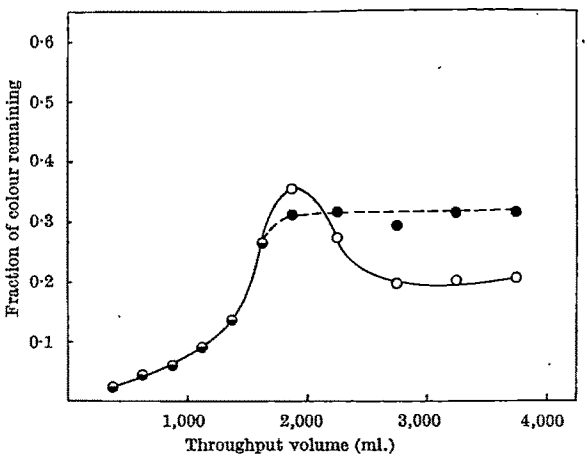

Fig. 3. Variation in colour of effluent from anion exchanger. —○—, First day test; - - - ● - - -, Third day test. Colour of untreated urine, 1,143 units

TEACHING BIOLOGY

By Prof. C. D. DARLINGTON, F.R.S.
Botany School, University of Oxford

THE various branches of science are perpetually changing their character and content. We are well aware of this general property of evolution for we regard it as the natural result of our own activities. Of the rules that may be said to govern it, however, we are less clearly aware. Indeed, we observe confusion rather than rule, paradox rather than principle. Sciences sometimes split; and they sometimes fuse. Continually they become more connected in their foundations. But continually their newest developments become more remote from these foundations. Their methods are transformed from the descriptive to the experimental, from the individual to the statistical, and from the analytical to the synthetic. The physical apparatus that they use is correspondingly transformed. What is more serious is that the kind of training and the type of intelligence and temperament needed by the man or woman who wants to pursue any branch of science by teaching or research is also transformed: and what happened formerly from generation to generation happens nowadays—to use our academic unit of time—from quinquennium to quinquennium.

This property of science is emphasized by the acceleration of discovery which has been one of the consequences of its regular teaching in universities. Regular teaching, however, has carried with it other quite different consequences: the need for a neat division into departments; for a hierarchy of professional teachers often permanently attached to the same department, and housed in great buildings; for routines of laboratory work served by convenient text-tooks which become stereotyped; for a system

of examinations administered by committees and regulated by statutes. All these needs have been met in our older universities: and they have created an establishment, massive and privileged, and in many respects fitted to resist the changes demanded by the processes of discovery and the growth of science which they are supposed to be encouraging.

The obstacles to change have been most forbidding in the sciences dealing with life. In the nineteenth century, when biological teaching developed in the universities, there was no single clear purpose in it. It might be designed as propaganda for a belief either in creation or in evolution. It might be intended as a preparation for medical training or as an introduction to the practices of cultivation. But whatever reasons were entertained the organization that came into being nearly always entailed a separation of botany and zoology. They were put in separate departments no doubt because, at the descriptive level of the time, the study of plants and animals appealed to different kinds of people: and for the same reason the study of man, with his unique theoretical and practical interest, was regularly and utterly excluded from both.

All this is quite recent. Lawrence's *Natural History of Man*, which was the climax of an age of amateurs, put man in the centre of the picture of life. That was in 1819 [1]. But when Huxley wrote his version of the same theme in 1863 and called it *Man's Place in Nature* he ushered in a professional age in which, by a *tour de force*, man was left out of his one obvious place in Nature; he was omitted from the study of life.

Thus for a hundred years, and quite systematically, man and all his activities have been cut out of biology in the universities. The separate parts of plant and animal studies have accordingly been presented as though they were without application to man and therefore to a large extent as though they were useless. In due course, this absence of application, like the separation into departments, has gradually come to be an end in itself. When agricultural teaching developed, universities found they had to create new departments or institutions which were not ashamed to discuss plants and animals in a useful way. Thus the study of life was broken up into smaller and smaller fragments, less and less connected in theory and less and less connected in practice.

In the present century the teaching of biology has for these reasons gone to pieces; and by a paradox the teaching has gone to pieces at the very time when research on living things and living processes was putting the pieces together. For the investigations of the cell and its heredity, the individual and its development, the community and its relations, the species and its evolution, have all the time been revealing internal and external connexions. All the time they have been bringing unity into the study of life and making it useful to man: and all the time they have been exposing the inadequacy of the methods of teaching the subject and of the institutions available for it.

This contradiction between our institutions and what we want from them has long been realized [2] and frequently [3] asserted. Many methods also have been used to resolve it. Above all, our predecessors arranged elementary courses which combined the teaching of botany and zoology with chemistry, physics and geology. Sixty years or more of experience of such courses has, however, proved disappointing. What they have produced, as Catcheside has put it in a valuable discussion [4], are obvious chimeras—at once monstrous and obsolete. The reason for this failure is now clear. Elementary courses have always dealt with the older parts of a science. The older parts of botany and zoology are based on description, and so far as possible naked-eye description. The union of life sciences occurs, however, through their newest growth: it is through the newest parts that we need to graft our living tissues. Our mistake has been that what is new we have held to be too advanced and too abstruse. To be sure what is new requires more refined chemistry, higher powers of the microscope, and a little more mathematics than are generally available in schools. But might these requirements not be met in universities?

To put the matter in another way: what we need in university biology is not a continuation of school teaching or adding together of old-fashioned parts of university subjects. For fundamental biology is not old botany plus old zoology; it is something new, created in the present century, not in the previous century. What we need therefore is a new approach to teaching which strides over barriers between old subjects and old departments, an approach to teaching which seizes on and exploits the newest discoveries. In this way we shall get the connected, integrative and useful character we need in the study of life.

Eminent scholars and scientists who manage universities, no less than those who do the humdrum work, have perhaps been more inclined to look back to their own achievements rather than forward to those of their pupils. The greatest effort to set a new course has been made in the United States. But even there only in a few universities has decisive progress been made. In most the innovations have not been possible, and the staff has not been available for carrying out any profound and up-to-date reorganization of teaching. In Great Britain also we shall have to surmount great obstacles before a provision for biological teaching, based on present understanding, will be possible.

In Oxford, following six years of laborious discussion, we have drawn up plans for a beginning of integrated teaching. We now feel able to undertake our programme at once. Beginning in October 1963 we shall have an obligatory one-year course as an introduction to biology [5]. It will be intended for pupils with a school training in biology, chemistry and physics to the Advanced-level of the General Certificate of Education. But it will not, we believe, be beyond those who are new to the subject. It will be divided into three biological sections: (1) genetics, including the chromosomes; (2) physiology with biochemistry; (3) ecology and taxonomy.

In addition, there will be special courses (the functions of which have been described by Catcheside) in chemistry, physics, geology and mathematics, each of them designed for biologists. The biological courses will make use in due proportion, as convenience dictates, of plant and animal, human and microbial, material. Each will have its experimental foundations. Each will have its analytical and also its integrative aspects. The result we hope will show the connectedness and organization which distinguish biology from the physical sciences; and it will also show the physical foundations on which this organization rests. All the teaching we intend to accommodate ultimately in a single building.

The problems of teaching, and of learning, involved in this programme are far from being simple, and indeed far from being solved. The work involved for the teacher and for the pupil will be great; and the expense of equipment will be heavy. But we believe we shall succeed because we know ourselves that biology makes sense, and we believe that the teacher and pupil will find it useful to show and to see the sense emerging from the very beginning. When the advantages of working together make themselves felt, we believe the boundaries between traditional departments will, at least at the elementary level, gradually dissolve.

Following the first-year course the undergraduate will decide whether to continue to an honours course in botany or zoology, agriculture or forestry. Which it is will indeed depend on what kind of sense he has made out of the first year, whether it was the practical or the theoretical sense; and what kind of material excites his interest—plant, animal or microbial.

That is how the matter stands at present. But it is clear that new possibilities of honours courses will arise

and new kinds of connexions will establish themselves from the reformed first year. The obstacles to these later steps will be very great. But they can scarcely be so serious as were those to this first step. A new world will be opened to the teacher, the pupil, and the university. How large a world it will be we may leave the future to discover. But it will certainly be a world which includes something of man and mankind: and it will probably be a world in which the teaching of biology has a place not far from the centre of university education.

DR. MARGARET MURRAY

TRIBUTE TO A CENTENARIAN

MARGARET ALICE MURRAY was born on July 13, 1863, in Calcutta; her parents' generation had witnessed the Indian Mutiny, but she grew up in the Golden Age when Britain's prestige and prosperity were at their height. The child's first journey home was by way of the Cape, for the Suez Canal was not open. She remembers rolling bandages for the wounded of the Franco-Prussian War, and her compassion was early aroused by her mother's devotion to the education of the women of India. Her own was that of a young girl of her time; but, not content with a social life, she worked in a local hospital and was soon 'in charge' of a ward.

She left India for good before she was twenty-five years old, her prodigious and accurate memory stored with impressions of the life and religion of many races and creeds, which were to stand her in good stead in her chosen career. Miss Murray was fortunate to become a student at University College in the newly formed Department of Egyptology when Sir Flinders Petrie was evolving a new science. They had to write their own text-books from direct observation, and a measure of Dr. Murray's contribution is seen in about a hundred books and articles. But more valuable still, two distinguished generations of archæologists are in her debt as a wise and witty teacher, who never forgets that her subject is the study of man, mentally and spiritually, from the time that he emerged from the animal.

Dr. Murray's excavations were carried out mainly in Egypt, Malta, Petra, Palestine and Britain. She retired from the assistant professorship of Egyptology in University College, London, in 1935. She is also well known for her studies in folk-lore and witchcraft.

Dr. Murray follows the discoveries of the space age with as much zest as she gave to the invention of the bicycle; her delight in her particular fields of research is undimmed and distilled in her latest book *The Genesis of Religion*. Her autobiography, *My First Hundred Years*, follows this month, and if she sometimes regrets that she has led an uneventful life, this is surely an understatement for someone who has lived gallantly through the adventure of one century and looks forward to the next.

NEWS and VIEWS

The Royal Society of Edinburgh: Foreign Honorary Fellows

THE following have been elected Foreign Honorary Fellows of the Royal Society of Edinburgh: Prof. M. Calvin, professor of chemistry, University of California, Berkeley; Dr. V. A. Engelhardt, director, Institute of Physico-Chemical and Radiation Biology, Moscow; Prof. A. Frey-Wyssling, professor of botany, Eidgenössische Technische Hochschule, Zurich; Prof. P. E. M. J. Pruvost, professor of geology, Paris; Prof. S. L. Sobolev, professor of mathematics, University of Moscow; Prof. W. Szafer, professor of botany, Cracow; Prof. V. F. Weisskopf, director-general, European Organization for Nuclear Research, Geneva.

Awards

DR. E. M. PATTERSON, Department of Mathematics, University of Aberdeen, has been awarded the Makdougall-Brisbane Prize for the period 1960–62 for his papers on linear algebras published in the *Proceedings* of the Society during the period of the award and earlier papers on cognate subjects also published by the Society. Mr. K. V. Blaiklock, Kenton, Exeter, has been awarded the Dr. W. S. Bruce Memorial Prize for 1962 commemorating Dr. W. S. Bruce, the Scottish explorer and scientific investigator in polar regions, in recognition of his contributions by way of navigation to the exploration of the Antarctic Continent and for his mapping of lands bordering the Weddell Sea.

The Royal Society of South Africa : New Members

At a joint meeting of the Society and the Astronomical Society of South Africa, held on April 17, at the South African Museum, Queen Victoria Street, Cape Town, the following were elected to membership: Mr. L. R. Alexander, Prof. S. Biesheuvel, Mr. M. Jehu and Dr. O. Williams.

Geometry at Oxford: Prof. M. F. Atiyah, F.R.S.

Prof. M. F. Atiyah, who has been appointed to succeed the late Prof. E. C. Titchmarsh (see *Nature*, 198, 1039; 1963) to the Savilian professorship of geometry at Oxford, is one of the leading experts in algebraic geometry, topology and differential geometry. He has been a reader in mathematics at Oxford since 1961 and has already made a considerable contribution to the development of pure mathematics there. He was born in April 1929 and was educated first in the Victoria College in Egypt and then at Manchester Grammar School. He discharged his military service with the Royal Electrical and Mechanical Engineers in the years 1947–49, and in the latter year he was elected a Scholar of Trinity College, Cambridge, where he proceeded to take the Mathematical Tripos as a wrangler in 1951, together with a distinction in Part III in 1952. He was awarded the first Smith's Prize in 1954 and obtained his Ph.D. in 1955. In the years 1954–58 he was a Research Fellow of Trinity College, Cambridge, during which period (1955–57) he also studied as a Commonwealth Fund Fellow at the Institute for Advanced Study, Princeton. He was an assistant lecturer and afterwards a lecturer and Staff Fellow at Cambridge during the years 1957–61, and also a member of the Institute for Advanced Study at Princeton from September 1959 until January 1960. He was elected a Fellow of the Royal Society in 1962. Prof. Atiyah is distinguished for his researches in algebraic topology, but his interest and influence extend over a wide field of pure mathematics.

United Kingdom Scientific Mission in Washington : Dr. J. A. Saxton

Dr. John A. Saxton has been appointed director of the United Kingdom Scientific Mission in Washington, D.C., and scientific attaché at the British Embassy there. He will take up his duties early in 1964, replacing Dr. Harry Hookway, who will be returning to the United Kingdom on completion of a three-year tour of duty. Dr. Saxton, who is forty-nine, has been deputy director of the Radio Research Station (Department of Scientific and Industrial Research) since 1960. He joined the Department in 1938, working in the Radio Division of the National Physical Laboratory until the Division developed into the Radio Research Station in the early 1950's. He is well known for work on the dielectric properties of the atmosphere and on investigations of radiowave propagation at very high frequencies.

The Cold Spring Harbor Laboratory of Quantitative Biology

The Carnegie Institution of Washington has transferred its two laboratory buildings at Cold Spring Harbor, Long Island, New York, to the Cold Spring Harbor Laboratory of Quantitative Biology. The Carnegie Institution will continue its present Genetics Research Unit on the premises. The Cold Spring Harbor Laboratory of Quantitative Biology has been organized by a group of eight universities and research institutes. Its director is Dr. John Cairns, formerly of the Australian National University at Canberra. The chairman of the board of directors is Dr. Edward Tatum, professor at the Rockefeller Institute of New York. The sponsoring institutions are the Albert Einstein College of Medicine, Brooklyn College, Duke University, the New York University School of Medicine, Princeton University, the Public Health Research Institute of the City of New York, the Rockefeller Institute of New York, and the Sloan-Kettering Institute. The Carnegie Institution established its biological research at Cold Spring Harbor in 1904, as the Station for Experimental Evolution, with Dr. C. B. Davenport as director. It became the Institution's Department of Genetics in 1921. The present name was adopted in 1962. It was there that, in the early 1900's, Dr. George H. Shull carried on the research that led to the development of hybrid corn, which enormously increased corn yields and brought economic gain to the United States alone of more than 10 million dollars. Other research at Cold Spring Harbor has included methods of changing the hereditary characteristics of plants by means of radiation and chemicals, leading to much new theoretical knowledge as well as to the development of new and more productive types of food plants and flowers. Fundamental work in genetics continues to-day at the Carnegie Institution's Genetics Research Unit at Cold Spring Harbor, of which Dr. Alfred D. Hershey is director. Also at the Unit is Dr. Barbara McClintock, well known for her work on the genetics of maize (Indian corn); she is a member of the board of directors of the new Cold Spring Harbor Laboratory of Quantitative Biology. The Carnegie Institution will provide an immediate grant of 10,000 dollars to the Laboratory.

The British Industrial Biological Research Association, Ltd.

Work has started on the erection of the laboratories of the British Industrial Biological Research Association on a site of 16½ acres at Woodmansterne Road, Carshalton, Surrey. The site is adjacent to the Medical Research Council Laboratories at Carshalton, where the Toxicology Research Unit, Neuropsychiatric Research Unit, Virus Research Unit and Laboratory Animals Centre are accommodated, and overlooks the Oaks Park. The buildings provide accommodation for laboratories, rodent rooms, dog kennels, animal administration, administration and information services, etc., totalling 18,900 sq. ft. The whole project is expected to cost £190,000 and equipment will cost an additional £50,000. Building operations commenced at the beginning of May and the estimated date of completion is May 30, 1964. The laboratories will house a staff of approximately 60 in the initial stages. The buildings will provide up-to-date and well-equipped accommodation for carrying out all modern techniques of toxicity testing, and provision is made for workers in the scientific disciplines of toxicology, experimental pathology, pharmacology, biochemistry and organic chemistry. They will enable the British Industrial Biological Research Association to provide first-class services for its member companies in its field of toxicology of food additives, cosmetics and toiletries.

Business Management Studies at Liverpool

The University of Liverpool has recently received grants totalling £107,000 towards the further development of Management Studies within the University. £84,000 of this sum has been contributed by Littlewoods Mail Order Stores, Ltd. The balance of £23,000 is being contributed jointly by the Government (through the University Grants Committee) and by the Foundation for Management Education. The University intends to extend the provision of management education for practising business men in the Department of Economics. Under this scheme a Management Development Programme has been provided for directors and senior managers operating in companies over a wide area of the North of England—approximately 300 have participated in this Programme. The emphasis throughout has been on directing business men's attentions to operational problems and the ways and means of raising operational performance. It is anticipated that the future organization of management studies within the University will be based on a number of

Faculties or Departments and will be inter-disciplinary. It may also involve the establishment of a special institute, governed by a committee or board representing the various interests both within and without the University. Further attention will be directed to analysing the implications of international management application and the forms of management organization and techniques applied to international business operations, while the study of the forces making for successful marketing management will also figure importantly in the programme.

Contributions of Science to the Resolution of International Conflict

A STUDY conference on "The Contributions of Science to the Resolution of International Conflict" was held at Windsor during June 28–July 1. The sponsors included Lord Boyd-Orr, Rear-Admiral Sir A. W. Buzzard, R. G. Cooke, Sir Charles Goodeve, Prof. A. Haddow, Dame Kathleen Lonsdale, Prof. G. Schwarzenberger and Prof. C. H. Waddington. The conference had two aims: to show how much scientific work has been done already towards the resolution of international conflict, and to develop ways of broadening the scope, accelerating the progress, and ensuring the relevance of future scientific research in this field. So far as the first aim was concerned, Prof. K. Boulding, Ann Arbor, Michigan, gave a brief historical summary of work done, or in progress. Concerning the second, it was felt that there are two tasks that must be tackled before it can be said that scientific work on international conflict is on a sound footing. First, research techniques and working arrangements are required that will enable different kinds of scientists to work fruitfully together. Secondly, a common language is needed or, at least, a body of translators between the scientists who do the research and the people who face the problems and want to apply the findings. Among those presenting papers were Dr. F. Emery, Stafford Beer and Dr. John Burton. Others participating included Prof. J. Meade, Prof. L. Penrose, Sir Charles Goodeve and Prof. G. Schwarzenberger.

Animal Health

THE Animal Health Trust has added to its campaigns by the introduction of a new popular magazine, *Animal Health* (Vol. 1, No. 1; January–March 1963. Journal of the Animal Health Trust. Pp. 1–76. London and New York: Pergamon Press, 1963. 5*s*.). With an impressive editorial board, it aims at providing interesting information about animal health subjects designed to appeal to a wide range of readers. The first number has a dozen articles: two are of a historical nature, the history of dogs, by Dorothy Hodgman, and the first outbreak of foot-and-mouth disease in Britain, by J. W. Barber-Lomax. Sir John Hammond provides a thoughtful article on nutrition during pregnancy, and Dr. W. R. Wooldridge discusses man and his animals. W. C. Miller has written a brief tribute to 'Hyperion' and also the first part of an article on the place of the horse in modern society in Great Britain. Ralph Wightman has an article on animal husbandry, and poultry interests are represented by articles on Newcastle disease vaccination, by J. S. Garside, and by the influence of the changing structure of the poultry industry on avian disease in the United Kingdom, by R. F. Gordon. With items on new products of interest to animal owners, notices about particular film-strips available, and some book reviews this is a very bright and useful journal.

Diseases of Free-Living Wild Animals

DR. A. MCDIARMID, of the staff of the Field Station of the Agricultural Research Council, at Compton, Berkshire, has written a monograph, *Diseases of Free-Living Wild Animals* (FAO Agricultural Studies No. 57. Rome: Food and Agriculture Organization, 1962). This is a much neglected subject; only in the past couple of decades has much attention been directed to the value as well as the necessity of bringing wild animal and bird life into the epidemiological environment of both human and animal disease research. Previously, certain 'peculiarities' had been recognized, such as the finding of an antelope with tuberculosis in a game reserve, without proper recognition that an important item in epidemiology was concerned. Decades ago a few enlightened workers realized the value of linking veterinary and medical epidemiology, but the opportunity to bring this about did not come easily. To younger workers these statements about former neglect might require justification, and the story of rabies emphasizes the role of wildlife. Earlier in the century it was believed that, if dogs were to cease to exist, rabies would cease to be important. We now know that there are few diseases with such a capacity to exist in the absence of any human or canine agency. It also shows the infinite capacity of the disease to take advantage of certain changes in environmental condition; with the political and military changes in Eastern Europe at the end of the Second World War possession of firearms by civilians was not possible, and, as a result, the balance of predatory animals changed; foxes and other biting animals increased in numbers, rabies became heavily prevalent and the disease spread steadily across continental Europe and became a serious problem, dogs being the victims rather than the main source of spread. The information provided in this monograph, covering scores of different infective conditions and at least one thousand references, will be of great value.

The Museum of Comparative Zoology, Cambridge, Massachusetts

DR. ERNST MAYR, in submitting his first report as director of the Museum of Comparative Zoology at Harvard College, feels that at the present time it is not desirable to make fundamental changes in the policy of the institution (Annual Report of the Museum of Comparative Zoology, 1961–62. Pp. 32 + 2 plates. Cambridge, Mass.: Museum of Comparative Zoology at Harvard College, 1963). The first task of a university museum is to serve as a combined centre of instruction and research. With six professors and twelve additional research zoologists on the curatorial staff the Museum is indeed well qualified to carry out this task. Active research is an inseparable part of instruction in the sciences. The Museum of Comparative Zoology has stressed research since the days of its founding by Louis Agassiz, yet in the whole history of the institution there has been no period of greater scientific activity and productivity than the present.

A Clay Fertility Figurine from Lower Austria

THE latest volume of the *Mitteilungen der Prähistorischen Kommission der Österreichischen Akademie der Wissenschaften* (Band 10. Pp. iv + 162. Wien: Hermann Böhlaus NACHF, 1960–62) consists of a detailed study of a clay fertility figurine from Lower Austria (Alois Gulder, Die urnenfelderzeitliche "Frauenkröte" von Maissau in Niederösterreich und ihr geistesgeschichtlicher Hintergrund). The figure was found during excavations of an early Hallstatt settlement between Haselbach and Maissau before the Second World War, and unfortunately its exact find-spot and associations are somewhat obscure. The author, however, has made a successful attempt to establish its contemporaneity with traces of an Urnfield hut of rectangular form. The pottery from the site, and the few metal objects, generally belong to the earlier Urnfields, Hallstatt A in this area, with a suggested date in the eleventh century B.C. The figurine is of clay, 75 mm tall and almost half as wide, with outstretched arms, rather gross facial features and small breasts. A large 'bun' over the head has probably influenced the author

into considering that this figurine has its closest analogues in the toad-like figures represented in many areas and belonging generally to the latter first millenium B.C. and after (from sites such as Dernovo, Bornholm and Vetulonia), although earlier examples are known (Vinča, Eberstadt). Such forms are generally believed to be closely linked with fertility cults, often associated with the idea of the embryo and womb, and the author produces many examples of this from Europe and Asia. It is, however, also possible that the Maissau figurine should lie not so much with this toad-like group as with the mother goddess idea, which is so well represented in the Mediterranean and the continental Neolithic, with perhaps a basis back, again in Austria, in the Upper Palæolithic Venus figurines of more than 20,000 years ago.

Constituents of Tobacco Smoke

The Tobacco Research Council (formerly the Tobacco Manufacturers' Standing Committee) have published a second supplement to their Research Paper No. 3, *The Constituents of Tobacco Smoke: An Annotated Bibliography*, which appeared in 1958 (Pp. ii+24. London: Tobacco Research Council. 1963). The second supplement, which is edited by E. G. N. Berry, refers to publications appearing during the period 1960–62, and more than one hundred references to papers on the estimation or identification of constituents of tobacco smoke are given. As in the earlier volumes, references are listed in sections based on classes of compound, and the bibliography provides a handy reading list in which publications on any particular compound or group of compounds in tobacco smoke can be easily located.

Antioxidants in Food : Detection and Determination

The coming into force of the Antioxidant in Food Regulations, 1958, has posed new problems for public analysts and other chemists as it has meant that certain foods have to be examined regularly for an additional number of compounds. The recent publication of a booklet by the Association of Public Analysts, entitled *The Detection and Determination of Antioxidants in Food*, will therefore be welcomed by many food chemists (Pp. ii+25. London: The Association of Public Analysts, 1963. 10*s*.). A scheme of analysis is presented in which the permitted antioxidants can be separately detected and determined on the same methanol extract. Gallates and butylated hydroxyanisole are determined by the blue colours produced with ferrous ammonium sulphate and Gibbs reagent respectively. The recommended methods for butylated hydroxytoluene make use of the new colorimetric test of Szalkowski and Garber (*J. Agric. Food Chem.*, **10** (6), 490; 1962), in which a purplish-red colour is produced with *o*-dianisidine and sodium nitrite. For a screening test the figure obtained is doubled to allow for the incomplete extraction of the antioxidant by the methanol. For more accurate results, however, it is necessary to separate the butylated hydroxytoluene first by steam distillation. Methods are also described for the identification of the permitted and various non-permitted antioxidants by reverse-phase paper chromatography and the corresponding R_F values are tabulated. Numerous practical tips, the effect of possible interfering substances and the results of collaborative trials are also included, together with summaries of the British and U.S. Regulations relating to antioxidants.

The Industrial Pest Control Association

The following have been elected officers and executive committee of the Industrial Pest Control Association for the year 1963–64: *President*, Dr. E. R. Goodliffe (Ratsouris, Ltd.); *Vice-President*, Mr. D. Boocock (S.D.C. Pesticides, Ltd.); *Honorary Treasurer*, Mr. D. M. Simpson (Cooper McDougall and Robertson, Ltd.); *Executive Committee*, Mr. S. Egleton (Verminex, Ltd.), Mr. S. Farrow (London Fumigation Co., Ltd.), Mr. B. Kesterton (British Insecticides, Ltd.), Mr. A. G. Stutely (Sorex (London), Ltd.) and Mr. E. L. Williams (Shell Chemical Co., Ltd.); *Secretary*, Mr. W. A. Williams, Cecil Chambers, 86 Strand, London, W.C.2.

Committee on Scientific Library Services

The Library Association has appointed a Committee on Scientific Library Services to review the existing provision of specialist library services for scientists, technologists and other specialist workers, and to make recommendations on the services needed and the staff required to provide them. Major-General C. Lloyd has accepted the chairmanship, and representatives of the Library Association include the chairmen of the Council and of the Executive, Mr. D. J. Foskett and Mr. F. M. Gardner. Representatives will be invited from universities, colleges, research establishments and industry.

Announcements

Dr. A. D. Booth has been appointed to a specially created inter-disciplinary research professorship in autonetics at Western Reserve University, Cleveland. The appointment will be held in parallel with the post of dean of the College of Engineering at Saskatchewan which Dr. Booth holds (see *Nature*, **195**, 946; 1962).

Dr. John O'Connor has been appointed research associate at the Institute for Scientific Information, Philadelphia. Dr. O'Connor, a specialist in information retrieval, is at present carrying out research on high-quality subject indexing by electronic computer. He was formerly associated with the University of Pennsylvania and Remington Rand Univac.

The fifth international conference on "Medical Electronics" will be held in the University of Liège during July 22–26. Further information can be obtained from Dr. F. Bostem, 23 Boulevard Frère Orban, Liège.

The third European Mycological Congress will be held in Glasgow during August 31–September 7. Further information can be obtained from Dr. J. G. Manners, Botany Department, the University, Southampton.

An international symposium on "Pollen Physiology and Fertilization" will be held at the University of Nijmegen during August 29–31. Further information can be obtained from Prof. H. F. Linskens, Department of Botany, Driehuizerweg 200, Nijmegen, The Netherlands.

The sixteenth International Congress of Zoology, organized by the National Academy of Sciences–National Research Council and the American Institute of Biological Sciences, will be held in Washington during August 20–27. Further information can be obtained from Dr. G. B. Moment, c/o National Academy of Sciences–National Research Council, 2101 Constitution Avenue, N.W., Washington 25.

A joint international conference on "Creep and Fracture", organized by the American Society of Mechanical Engineers, the Institution of Mechanical Engineers and the American Society for Testing Materials, will be held in New York during August 25–29 and in London during September 30–October 4. Further information can be obtained from the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1.

Erratum. In the communication by W. L. Templeton and V. M. Brown, entitled "The Accumulation of Calcium and Strontium by Brown Trout in Waters in the United Kingdom", published in the April 13 issue of *Nature*, on p. 199, column 2, line 51 should read: "1/2,000th of the M.P.C. as calculated here", not "1/2,000th of the $(M.P.C.)_w$ as calculated here", and line 54 should read "one-twentieth of the calculated M.P.C", not "one-twentieth of the calculated $(M.P.C.)_w$".

THE ASSOCIATED ELECTRICAL INDUSTRIES LEVITRON

By Dr. N. L. ALLEN, Dr. D. BALFOUR, V. C. CLOKE, R. F. HEMMINGS, T. P. HUGHES, B. JORDAN, B. S. LILEY, H. B. MUNDY, Dr. R. M. PAYNE and Dr. A. A. WARE

Research Laboratory, Associated Electrical Industries, Ltd., Aldermaston Court, Berkshire

THE levitron, first proposed by Colgate and Furth[1], is a toroidal version of the linear hardcore or inverse pinch discharge[2,3]. The object of such machines is to produce hydromagnetically stable plasma, where the term 'hydromagnetic' refers to those theories which assume infinite plasma conductivity. In cylindrical geometry a sufficient condition for this type of stability is that the inequality:

$$j_z B_\theta < 0 \qquad (1)$$

should be satisfied throughout the plasma. j_z is the axial current density and B_θ the azimuthal magnetic field. In the linear experiments this condition is automatically satisfied. In toroidal geometry the condition[4] corresponding to equation (1) is more complicated, and it is neither obvious nor certain that hydromagnetically stable configurations exist. On the other hand, a toroidal system has the advantage of eliminating end effects and enabling plasma to be produced over a wider range of initial gas pressures.

In addition to hydromagnetic instabilities, others may occur. Of these, current[5] and resistive[6] types are proving to be of importance. The object of the investigation reported here is to determine the nature of the instabilities that can occur in a levitron machine, and estimate the importance of these in energy- and particle-loss processes. So far few results of a conclusive nature have been obtained; but many interesting and encouraging observations have been made. The purpose of this article is to report on these, and give a brief description of the design and operation of the machine.

The vacuum vessel is a torus with a major diameter of 92 cm and a minor diameter of 30 cm. It consists of eight aluminium pressings with walls 1·25 cm thick. It is constructed in such a manner that gaps requiring vacuum seals run in both the toroidal (φ) and poloidal (θ) directions. These seals are of 'Viton' rubber and are protected from the plasma by silica tape. The tape is held in position by copper strips riveted to the aluminium (Fig. 1). The hardcore is also of aluminium, being a toroidal tube of the same major diameter as the vacuum vessel. The minor diameter of this tube is 11·4 cm, the wall thickness 0·63 cm and the weight 14 kg. For the duration of an experiment ($\sim$ 1 msec) the hardcore is unsupported and co-axial with the vacuum vessel.

On the outside of the torus are two sets of windings which run in the θ and φ directions respectively. These are connected via switches to the condenser banks referred to below. A transformer iron core links the torus.

The operation of the machine is best understood by reference to Figs. 1 and 2. Initially the hardcore is at the bottom of the torus resting on four aluminium pads, 8 mm high and 2·5 cm wide. The levitation condenser bank is discharged through the axial or φ windings. Interaction between the current in the hardcore and the eddy currents induced in the walls of the torus gives the hardcore an impulse. This impulse is sufficient to raise the core to the centre of the torus, where it interrupts a light beam. This generates a pulse which triggers the main φ condenser bank (the nomenclature refers to the direction of the induced electric field in the torus). The resulting current in the hardcore is clamped at its peak value.

Subsequent to clamping, a radio-frequency preionizing pulse (100 μsec duration) is applied, and at the end of this the θ bank is fired. This breaks the gas down and drives the plasma towards the hardcore. The azimuthal magnetic field, B_θ, is trapped in the process. The position of the discharge at any instant of time is determined by the value of I_θ and the initial value of the current in the hardcore. The θ bank is also clamped. As the core returns to its original position at the bottom of the torus it is 'caught' by the catching bank. In a different mode of operation the sequence of firing the main φ and θ banks is reversed. In this way a pinch-type[7] discharge is produced with, however, a hardcore present.

In normal levitron operation trapping of the B_θ field ensures that:

$$j_\varphi B_\theta < 0$$

where j_φ is the axial current density in the plasma. As already pointed out, this is not a sufficient condition for hydromagnetic stability in a torus; but it is a basic requirement for this condition to be satisfied.

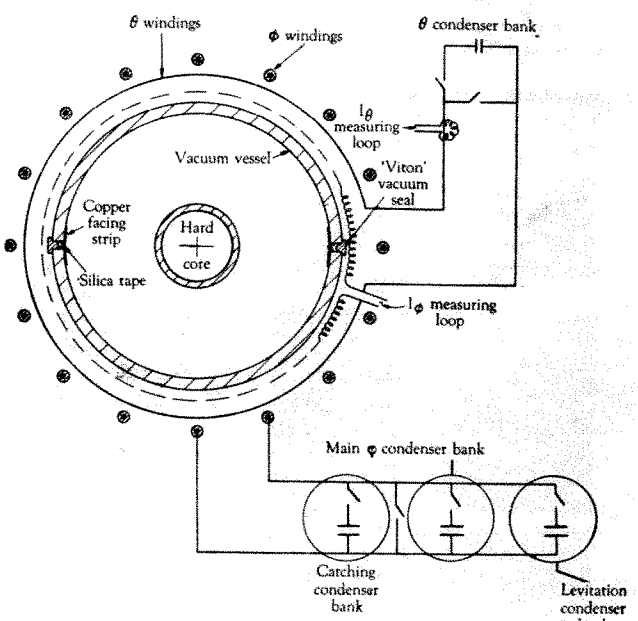

Fig. 1. Schematic diagram of levitron

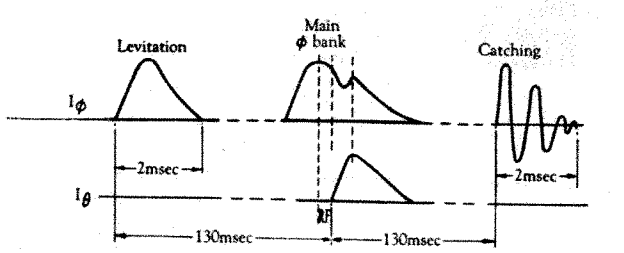

Fig. 2. Levitron trigger sequence. Upper, I_φ currents; lower, I_θ

The energy required for levitation is about 3,600 joules and that for 'catching' of the same order. The turns ratio of both the φ and θ windings can be 8 : 1, 16 : 1 or 32 : 1. The characteristics of the main φ and θ banks are given in Table 1.

Table 1

Main φ bank	Charging voltage, V_φ	20 kV max.
	Capacitance	94 μF
	Peak hardcore current (in absence of plasma)	~12 kamp/kV
	Current rise time at 32 : 1 turns ratio	400 μsec
	1/e clamp time at 32 : 1 turns ratio	2·5 msec
θ bank	Charging voltage, V_θ	20 kV max.
	Capacitance	423 μF
	Peak magnetic field, B_φ (in absence of plasma)	~350 gauss/kV
	Current rise time at 16 : 1 turns ratio	110 μsec
	1/e clamp time at 16 : 1 turns ratio	430 μsec
	Initial azimuthal electric field, E_θ, at walls of torus for 16 : 1 turns ratio	~1/3 V/cm/kV

The maximum repetition rate of the machine is one discharge per minute. This is limited by the rate at which the hardcore can cool. The normal working pressures are 2 millitorr and 4 millitorr. However, discharges have been obtained at pressures as low as 6×10^{-2} millitorr and as high as 16 millitorr. No attempts have been made to operate at a higher pressure. Most work has been done in hydrogen; but several experiments have also been carried out in helium and argon.

On three occasions faults and modifications have necessitated the dismantling and re-assembly of the machine. In the first assembly (September–October 1961) the only observations made were those required to test the engineering performance. During the period February–May 1962, a successful series of experiments were carried out in the second assembly. In the third assembly (August–October 1962) levitation was unreliable, the fault being traced to distortions in the hardcore. Even so, many interesting results were still obtained from experiments in this assembly. In the fourth assembly a new copper hardcore (weight 23 kg, minor diameter 8·9 cm) will be used. In addition, extra facilities for probe and spectroscopic observations will be included and the θ and φ turns ratios will be increased to 64 : 1. This assembly is at present in the process of construction.

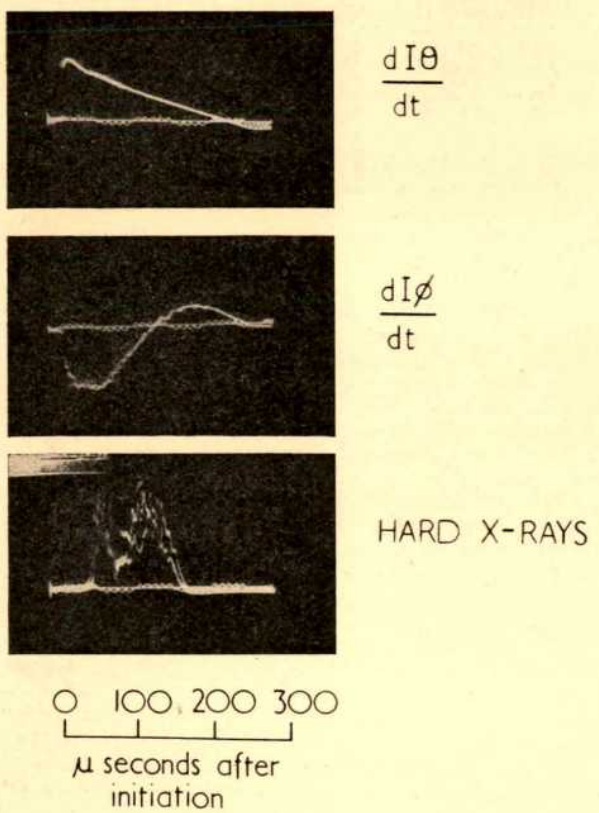

Fig. 3. $\dot{I}_\theta$, $\dot{I}_\varphi$ and hard X-rays as a function of time in hydrogen. V_θ = 10 kV; V_φ = 12 kV; press = 4 millitorr. θ turns ratio = 32 : 1 overlay of three discharges

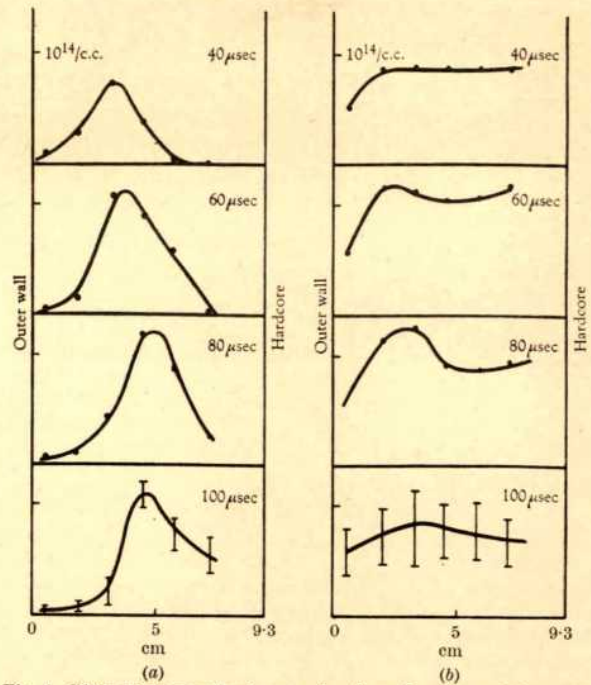

Fig. 4. Plots of plasma density as a function of radius and time: (*a*) for normal levitron operation; (*b*) for *Sceptre* type operation in the levitron. Condition for (*a*): $V_\theta = V_\varphi = 10$ kV; $p = 4$ millitorr. θ turns ratio = 32 : 1

Measurements have been made with double Langmuir probes, magnetic probes, a Hilger medium quartz spectrograph and two monochromators. In the third assembly observations were also made on X-rays, and streak photographs were taken with a rotating mirror camera. Measurements of I_φ and I_θ (Fig. 1) and the volts per turn in both the φ and θ directions have been made under all conditions.

I_φ is the sum of the axial gas and hardcore currents. The decrease in this quantity on the application of the θ bank, as shown in Fig. 2, is a measure of the gas current. This current is a function of $V_{\dot{\theta}}$ and V_φ and is of the same order as that in the hardcore. The gas currents cease to be measurable soon after clamping of the main θ bank (see Fig. 3), but plasma persists for an appreciably longer time (~500 μsec).

As measured by the Langmuir probe, the maximum value of electron temperature, T_e, so far recorded is $2{\cdot}3 \times 10^5$ °K. This was obtained for a θ turns ratio of 16 : 1 and V_θ = 13·5 kV, V_φ = 12 kV. For higher values of V_θ there is little or no increase in T_e. For very low values of V_θ the discharge is relatively clean, but for V_θ greater than about 12 kV large quantities of silicon and oxygen, among other impurities, are present. Ov was observed in the second assembly, but it was not sufficiently intense to allow an estimate of ion temperature to be made.

With low energies on the θ bank, the Langmuir probes give ample evidence of the plasma leaving the walls of the torus (Fig. 4*a*). This is confirmed by the streak photographs. In Fig. 5 part of the hardcore and plasma are obscured by the walls of the torus. Comparison of the ion density plots with H_β oscillograms indicate that high degrees of ionization (~ 100 per cent) are achieved by the time the gas current reaches peak value.

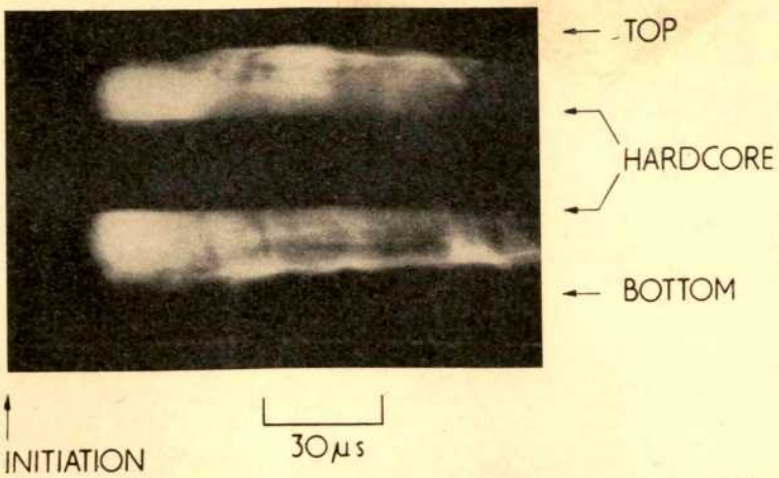

Fig. 5. Streak photograph of hydrogen discharge in levitron. $V_\theta = 10$ kV; $V_\varphi = 12$kV; press. = 2 millitorr; θ turns ratio = 32:1

Magnetic probe measurements have been made as a function of radius and time. As shown in ref. 8, subject to certain assumptions, current densities, pressure distributions, electric fields, mass velocities and conductivities may be deduced from these. Using these results energy containment times may be obtained. The details of this analysis, as applied to the levitron, will be given in a subsequent paper. The estimates of the energy containment times, although at present crude, are not greater than 10–20 μsec.

The perturbing effects of a probe have yet to be fully investigated, but a probe is known to have a marked effect on the production of X-rays. In the absence of a probe the X-rays begin almost immediately the discharge leaves the walls of the torus. However, with a probe, or to be more exact a probe envelope present, comparison between the streak photographs and hard X-ray (> 30 keV) oscillograms shows that the X-ray intensity is almost negligible until the plasma has moved beyond the end of the envelope. In one experiment in which the hardcore was supported on insulated rods, no hard X-rays at all were observed. In general, such rods appear to have undesirable effects and they have been utilized in only a few experiments. The origin and spectra of the X-rays have yet to be fully investigated.

All types of measurements show fluctuations. In most cases, however, these are small and under certain conditions of operation the good reproducibility of the $\frac{dI}{dt}$ and X-ray oscillograms is remarkable (Fig. 3). Likewise, fluctuations in the magnetic field are small, being only a few per cent of the mean value.

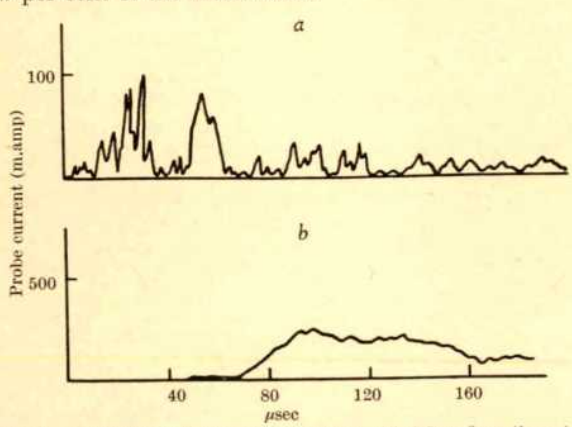

Fig. 6. Langmuir probe traces in hydrogen. (*a*), 0·5 cm from the outer wall; (*b*), 7 cm from the outer wall. $V_\theta = V_\varphi = 10$ kV; $p_h = 4$ millitorr; θ turns ratio = 32 : 1

On the other hand, the fluctuations in ion density can be large. Expressed as a percentage they are small near the hardcore but large near the torus wall (Fig. 6). The reproducibility of these measurements at $t = 100$ μsec is indicated in Fig. 4. The density plots shown in this figure were obtained by using a double-electrode Langmuir probe, and not a multiple set. Overlays of three oscillograms, of the type displayed in Fig. 6, at six different radii were used. It has been confirmed that these fluctuations are due to changes in ion density and not electric fields.

To obtain a better understanding of the significance of these fluctuations the following experiment was carried out. A pinch-type discharge, produced in the manner already described, was compared with a normal levitron discharge. In an attempt to make the comparison meaningful, the following parameters were kept the same in the two experiments: the initial gas pressure, the rise time of the gas currents, the initial electric fields at the walls of the torus, the pinch parameters $\left(\text{determined by the ratios } \frac{V_\theta}{V_\varphi} \text{ and } \frac{V_\varphi}{V_\theta}\right)$ and the energies on those condenser banks that initiated the plasma.

The electron temperature proved to be the same in both types of discharge, while even in the pinch-type the magnetic field fluctuations were small (due no doubt to the presence of the hardcore). However, in the case of pinch operation the plasma density was relatively high near the walls of the torus and fluctuations were large (Fig. 4*b*). Furthermore, arc damage, which in normal levitron operation was confined to regions near the gaps, was distributed at random over the walls of the torus. Again, from magnetic probe measurements made during pinch-type operation it was possible to show that Suydam's criterion[9] was violated at all radii for all times. The significance of these results will be discussed in the next section.

One feature of this comparative experiment was that in pinch-type operation the axial gas current was appreciably larger than that in the corresponding levitron case. This was not, nevertheless, believed to be a basic fault with the experiment. The stability behaviour of the levitron-type plasma is not markedly dependent on the axial gas current.

The rapid decay of the gas currents, subsequent to clamping of the θ bank, and the low estimates of the energy containment times are quite consistent with a relatively high level of impurity and an associated low electron temperature. Although these results are significant a more important measure of the effectiveness of the levitron configuration is the particle containment time. This can be estimated in the following manner.

On the assumption of cylindrical symmetry, and extrapolating in the vicinity of the hardcore, density plots of the type shown in Fig. 4*a* may be integrated to give the number of trapped ions as a function of time. For a 32 : 1 θ turns ratio this number goes through a maximum after about 70 μsec and then begins to decay. At a 16 : 1 θ turns ratio the time to reach a maximum is 40 μsec. During the decay the H_β signal is small and the decay time may be taken as a measure of particle containment.

In the second assembly these decay times, prior to clamping of the θ bank, were 50 μsec for a 16 : 1 θ turns ratio and 150 μsec for a 32 : 1 θ turns ratio. In the third assembly they were somewhat shorter, 70 μsec at 32 : 1, but this may have been associated with the erratic behaviour of the hardcore. Following clamping, the times for a 32 : 1 turns ratio are about twice as long. Insufficient

information was obtained to estimate the equivalent result for a 16 : 1 turns ratio.

The maximum number of trapped ions in hydrogen does not appear ever to exceed 30 per cent of the initial filling. Although charged particles are undoubtedly being lost it is also possible that during the early stages, when the H^β is still large, the escape of 'fast' neutral atoms (~ 2 eV) produced in the dissociation of H_2 may also be contributing to the loss processes.

The particle containment times are short, but there is no evidence as yet that they are limited by an instability. In fact it is probable that they are merely representative of the time taken for a particle to be driven into the hardcore by the applied $E \wedge B$ forces and induced pressure gradients. The streak photographs imply mass velocities of the order of 10^5 cm/sec, directed towards the hardcore, while the analysis so far carried out on the magnetic probe results and general electrical measurements suggest similar values. The exact values of these velocities are, of course, among other variables, functions of time, radius and θ turns ratio.

The behaviour of the hard X-ray intensity, as the plasma moves beyond the end of a probe envelope, implies good containment of the magnetic lines of force.

The large ion density fluctuations are not incompatible with the small magnetic field fluctuations. It has been pointed out by Wesson[10] that it is most likely that $\delta p \sim \delta\left(\frac{B^2}{2\mu_0}\right)$ (M.K.S. units). B is the magnetic field, p the kinetic pressure. That is, $\frac{\delta p}{p} \sim \frac{2B^2}{2\mu_0 p}\frac{\delta B}{B}$. Therefore, for a value of $\frac{B^2}{2\mu_0 p} = \frac{1}{\beta} = 5$; a 5 per cent fluctuation in B could correspond to a 50 per cent fluctuation in p. The magnetic probe results indicate that β is relatively small and values of this parameter even less than 1/5 are not unreasonable.

Finally, a brief comment must be made on the comparison experiment. In the case of the pinch, the fact that Suydam's criterion was violated accounts for the observed instability. In the case of the inverse pinch, however, the fact that $j_z B_\theta < 0$ automatically ensures that Suydam's criterion is satisfied, and this criterion is of no help in assessing the stability of such plasmas. As already pointed out, for normal levitron operation, the condition corresponding to equation (1) is much more complicated and so far the measurements necessary to test this criterion have not been performed. Therefore it is possible that the fluctuations observed in normal operation are also of hydromagnetic origin. However, whether or not this is the case there is little doubt that the containment properties of the normal levitron type discharge are superior to those of the pinch.

The levitron discharge is more stable than a toroidal pinch discharge and shows better isolation of the plasma from the walls of the torus. However, there is still an instability, the nature of which is unknown at present. There is no evidence as yet to show that this instability limits the particle containment time or the electron temperature. In fact, it is probable that particles are lost by normal collisional processes and that the electron temperature is limited by the presence of impurities. It is believed that these impurities are associated with arcing at the gaps. In an attempt to avoid this trouble both the θ and φ turns ratios are to be increased to 64 : 1 in the next assembly.

This work is being done under contract to the Culham Laboratory of the U.K. Atomic Energy Authority and we thank the members of that Laboratory for their interest. We also thank the many members of this Research Laboratory who have contributed to this project. In particular we acknowledge the interest and encouragement of Dr. T. E. Allibone and Dr. D. R. Chick; Mr. P. Tanner for the design and construction of much of the electronics; Mr. J. B. Hansell for assistance in many of the engineering problems, particularly levitation, and Mr. J. A. McKinnon for the daily maintenance and operation of the machine. Finally, we thank Sir George Thomson for his interest in this work and Dr. T. E. Allibone, director of the laboratory, for permission to publish this paper.

POST-TERTIARY SPECIATION IN EUROPE

IF the present distribution of species and sub-species in animals and plants is drawn on a map, the boundaries represent geographical discontinuities. In the past these boundaries have fluctuated as migration has proceeded. Phylogenetic patterns are produced by the interaction of such fluctuating boundaries with evolutionary changes arising from a variable rate of morphological modification. The Systematics Association attempted to explore the nature of such patterns during a symposium held at the University of Leicester in April 1962. The symposium, which was confined to the discussion of the speciation process during post-Tertiary time in Europe, was arranged in three sessions under the chairmanship of Dr. J. P. Harding (president), Prof. T. G. Tutin and Prof. P. C. Sylvester-Bradley respectively, and culminated in a vigorous discussion led by Prof. F. E. Zeuner.

Prof. F. E. Zeuner (Institute of Archæology, University of London) directed attention to varying rates of speciation. Palæontological evidence for the rate of speciation is best assessed on the assumption that taxonomists in each of the groups in question apply the same species concept to both Recent and fossil material. Usually, and for obvious reasons, the time-rates of morphological change are studied in fast-evolving groups. In some groups, however, species survive for a long time as, for example, in the Mollusca (Table 1). That species should maintain their stability for such long periods is possible only if either their rate of genetic mutation is very slow, or if all or most mutations are weeded out by natural selection as fast as they appear.

Table 1. Java—Marine Mollusca

Age in million years		Species indistinguishable from Recent forms (per cent)
30	Miocene	10– 30
10	Pliocene	50– 70
1	Pleistocene	80– 90
0	Holocene	100

Mammals and insects present a different picture. In mammals, no Recent species are known that are older than the Pleistocene, and only a few from the beginning of the Pleistocene—among them *Cervus elaphus* L. Even in the late Tertiary, there is an abundance of genera which are

now extinct. Insects are somewhat more conservative; there are even a few species in the Tertiary which have been regarded as identical with Recent ones. Many Recent insect genera, however, existed in the late Tertiary, though their number decreases with increasing geological age. Three groups may be used to illustrate this. In Tables 2–5, genera and sub-genera, and species and sub-species, respectively, are combined.

Table 2. Percentage Analysis of 92 Species of Fossil *Apoidea* (Bees)

	Extinct genera with extinct species (per cent)	Recent genera with extinct species (per cent)	Recent genera with recent species (per cent)
Eocene	94	6	0
Oligocene	50	50	0
Lower Miocene	38	60	2
Upper Miocene	24	76	0
Pleistocene	0	0	100

The two 'Recent' species recorded from the Lower Miocene are probably spurious. The honey bee, however, presents a case of exceptionally slow evolution. During 30 million years, since the Oligocene, it has scarcely changed at all. Palæontological and cytological evidence suggests that evolution came virtually to a standstill when polyploidy appeared and when the social structure of the hive had isolated the queen from the external environment[1].

Table 3. Percentage Analysis of 75 Species of Fossil *Lepidoptera* (Butterflies and Moths) (Ref. 5)

	Extinct genera with extinct species (per cent)	Recent genera with extinct species (per cent)	Recent genera with recent species (per cent)
Eocene	96	4	0
Oligocene and Lower Miocene	85	15	0
Upper Miocene	50	50	0
Pleistocene	0	29	71

Table 4. Percentage Analysis of 46 Species of Fossil *Saltatoria* (Grasshoppers S.L).

	Extinct genera with extinct species (per cent)	Recent genera with extinct species (per cent)	Recent genera with recent species (per cent)
Eocene	72	28	0
Oligocene	30	70	0
Lower Miocene	55	45	0
Upper Miocene	80	20	0
Pleistocene	0	54	46

The number of species included in these tables is too small to show consistent rates of change, but the trend is clear, especially when the three groups are combined (Table 5) and plotted on the time scale (Fig. 1).

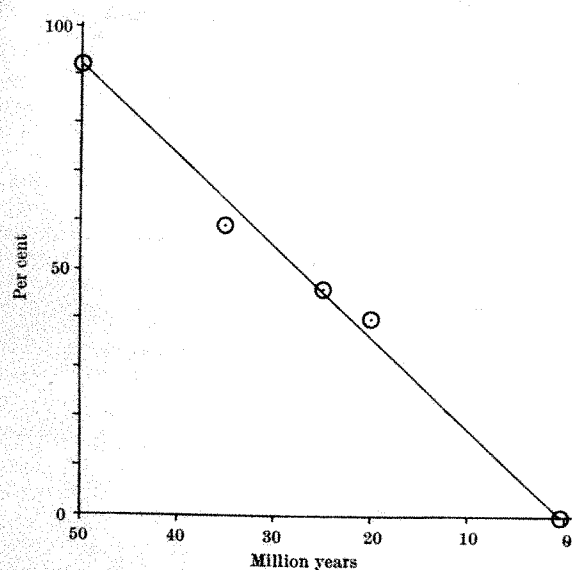

Fig. 1. Percentage of insect species now extinct plotted against geological age. Data from Table 5

Table 5. Percentage Analysis of 212 Species of Fossil *Apoidea*, *Lepidoptera* and *Saltatoria*

	Extinct genera with extinct species (per cent)	Recent genera with extinct species (per cent)	Recent genera with recent species (per cent)
Eocene	92	8	0
Oligocene	59	41	0
Lower Miocene	46	52	2
Upper Miocene	39	61	0
Pleistocene	0	29	71

Table 5 shows that the decrease in the number of extinct genera appears to be a simple function of time. While 50 million years ago 8 per cent of the genera were identical with Recent ones, at the beginning of the Pleistocene, 1 million years ago, all genera were Recent. But the Pleistocene contains as many as 29 per cent of extinct species (and sub-species), which elucidates to some extent the rate of change in the lowest systematic categories. The East African copal contains a few species not known to be living, but this may be due to insufficient knowledge of the Recent East African fauna.

The most informative Pleistocene site is Starunia, in the Carpathians, of early Upper Pleistocene age and belonging to a cold phase. Its *Saltatoria* have been studied in detail[2].

The nine species represented can be classified as follows:

Extinct, related to, but more highly specialized than, a localized Recent species in Montenegro	1
Extinct, intermediate between a Recent species in Montenegro and one in Altai Mountains	1
Very close to Altai species, perhaps a geographical race	1
Identical with Recent Asiatic species	1
Identical with Recent holarctic mountain species	5

No progressive evolution is present, but extinction has occurred of one species and of one geographical race whereby a cline was disrupted so that two separate Recent species are recognized.

Finally, the Isle of Jersey, Channel Islands, which has been separated from the Continent for about 7,000 years, has produced, among 21 species of *Saltatoria*, 2 distinct geographical sub-species and one dwarf form which is not morphologically different from the Continental form[3]. In addition, there is a local colour form of a shrew, and the red deer evolved an insular sub-species in the Last Interglacial which is now extinct[4]. This evidence suggests that minor geographical sub-species or ecological forms have appeared within 7,000 years, but that for the evolution of full species a hundred thousand years are (normally) insufficient, while half to one million years is a reasonable estimate for the time required. No insect species are known with certainty to have survived from the Miocene, but as an example of abnormal, slow evolution, the honey bee must be recalled. Generic differences have not appeared during the Pleistocene but Recent genera are known to have lasted for at least 50 million years, among them *Drosophila*.

In mammals, evolution appears to have been somewhat faster than in insects; in marine groups (Mollusca) it proceeds more slowly. The slow rates suggested by palæontological evidence suggest that the apparently fast rates deduced in some groups from Recent evidence apply to stabilized populations of ecotypes, to isolated communities exhibiting insignificant mutations, and, in plants and, in very rare cases, in animals, to polyploids.

Speciation studies in animals have been particularly illuminating in mammals, in birds and in butterflies, and each of these groups was dealt with by a separate speaker.

Dr. G. B. Corbet (British Museum (Natural History)), speaking of recent work on the British microtine rodents, emphasized how often breaks in the regularity of a cline are correlated with geographical discontinuities. Thus the short-tailed field mouse (*Microtus agrestis*) is represented by two parallel north–south clines in Britain and Scandinavia, affecting the pattern of the upper molar teeth. In Britain the greatest discontinuity on the mainland is across the Scottish Great Glen. Presumably the chain of lochs and rivers in the Great Glen is a barrier to gene flow. Other discontinuities separate island races, and it is

hoped to extend the investigation by applying more rigorous quantitative techniques to fossil material.

Prof. K. H. Voous (University of Amsterdam) showed that in birds the speciation process in Europe differed markedly from the adjacent palæarctic region to the east (Asia). Some indication of post-Tertiary species-formation can be detected in 43 per cent of the birds at present breeding in Europe. While Europe was the scene of active speciation, Asia provided a reservoir of 'old' species, only a few of which remained as relics in Europe. Notable among these relics is the Corsican form of the black-capped nuthatch, *Sitta canadensis whiteheadi*, which, as Löhrl[6] has shown, has developed marked differences in social and reproductive behaviour. That southern Europe formed a refuge for birds during times of glaciation, and was during these times isolated from the Asiatic reservoir, is shown by the interaction of the green woodpecker (*Picus viridis*) with the grey-headed woodpecker (*P. canus*). The former has re-colonized Europe from the south, the latter from the east. In the greater part of central and eastern Europe, and in small areas of Scandinavia, they now occur alongside each other, and behave as distinct though sibling species, with some degree of ecological differentiation[7–9]. Other cases with a similar history are listed in Table 6*a*. In yet other cases, the period of isolation has not resulted in a fully specific differentiation. In many the subsequent re-colonization from the two directions has resulted in zones of hybridization between sub-species in which the amount of individual variation is extremely wide (Table 6*c*). There are also certain cases where the degree of differentiation achieved during the period of isolation seems to be intermediate between that of the species and that of the sub-species (Table 6*b*).

Table 6

Species or race re-colonizing from the South	Species or race re-colonizing from the East
(*a*) Pairs in which specific differentiation has been achieved (ref. 9):	
Picus viridis	*P. canus*
Milvus milvus	*M. migrans*
Alectoris rufa	*A. graeca*
Porzana parva	*P. pusilla*
Strix aluco	*S. uralensis*
Galerida theklae	*G. cristata*
Regulus ignicapillus	*R. regulus* (ref. 10)
Parus caeruleus	*P. cyanus*
Certhia brachydactyla	*C. familiaris*
Emberiza cirlus	*E. citrinella*
Fringilla coelebs	*F. montifringilla*
Luscinia megarhyncha	*L. luscinia* (ref. 10)
(*b*) Pairs in which differentiation is intermediate in rank between species and sub-species	
Buteo [*buteo*] *buteo*	*B.* [*buteo*] *vulpinus* (ref. 11)
Corvus [*corone*] *corone*	*C.* [*corone*] *cornix* (ref. 12)
(*c*) Pairs in which sub-specific differentiation has been achieved	
Dendrocopos major pinetorum	*D. major major* (ref. 8)
Dendrocopos minor hortorum	*D. minor minor* (ref. 8)
Lanius excubitor galliae	*L. excubitor melanopterus* (refs. 13 and 14)
Aegithalos caudatus aremoricus	*A. caudatus caudatus* (ref. 15)
Sitta europaea caesia	*S. europaea europaea* (ref. 16)
Pyrrhula pyrrhula europoea	*P. pyrrhula pyrrhula* (refs. 15 and 17)
Garrulus glandarius glandarius	*G. glandarius brandtii* (ref. 18)

The southern refuge area was further complicated by the fact that the intricate Mediterranean coast-line, with its three isolated peninsulas, led to some differentiation into West Mediterranean and East Mediterranean forms.

Mr. L. G. Higgins (Chobham) recognized three contrasting patterns in the speciation of European butterflies. The first group (Holarctic) is an extension of the fauna of northern Asia to most of Europe, including the Arctic and the Central Alps, and often to North America. Despite the vast distribution area, there is little regional variation, and sub-species are rare. Some, like *Colias palaeno* L., show ecological modifications. The second faunal pattern is developed in Mediterranean areas, and has originated in the Near East. There are many localized indigenous species, and sub-specific differentiation is common. This fauna includes the Lycaenids; the taxonomic situation is complicated by a great diversity in chromosome numbers. Finally, there is a unique pattern of speciation in the mountain ringlets of the genus *Erebia*, which, despite a holarctic distribution, shows a concentration of well-defined species in the Central Alps. Some of these are confined to one or two alpine valleys. Others, with a wider distribution, show marked geographical variation. They appear to have originated in the Alps from pre-Quaternary stocks, and active speciation is now in progress.

Three speakers dealt with the processes of post-Tertiary speciation in flowering plants. Dr. V. H. Heywood (University of Liverpool) pointed out that speciation is essentially an experimental term and implies the origin and development of reproductively isolated gene-pools. The species utilized in most phytogeographical considerations are taxonomic species and are based on morphological discontinuities in the variation pattern. They are known to represent very different evolutionary situations. In considering post-Tertiary speciation we are bound to use data concerning the present-day distribution of species which are seldom known from an evolutionary point of view. As a consequence, whether speciation is considered to have occurred or not is a matter of taxonomic judgment. This was illustrated by reference to recent studies on the cytology and taxonomy of British and European *Leucanthemum vulgare*, where different polyploid races are only with considerable difficulty separable on morphological criteria such as pollen-size. Such cryptic 'species' may come and go in the fossil record without our even knowing it, relying as we do on exomorphic features.

In considering the post-Tertiary speciation of Angiosperms the following lines of evidence should be considered: (1) Present-day distribution and ranges of species which can at best provide indirect evidence concerning what happened in the past. This relies heavily on taxonomic judgments. (2) Palæobotanical data which will tell us what happened, when the material available is adequate and there are good sequences. This approach is well illustrated by the Quaternary studies of Godwin and the Cambridge school providing factual information concerning the successions and migrations of floras in the post-glacial periods and earlier. (3) Cytology, genetics, ecology and physiology of contemporaneous species tells us how speciation happens to-day and, by extrapolation, how it probably happened in the past. The most fruitful approach to an understanding of post-Tertiary speciation will come from a study of present-day populations by experimental cultivation to assess their ranges of variability in different parts of their area, their possible biotype de-pauperation during migrations, the influence of geographical isolation; by cytogenetic studies to tell us about their fertility relationships; and by morphogenetic and physiological studies to tell us about their tolerance and powers of extension. Such a combined approach will, as Böcher has said recently, raise many discussions of the evolution of taxa from a purely theoretical level to a factual basis.

The bearing of polyploidy on speciation was then considered in detail, since the polyploid nature of present-day taxa is one of the main lines of evidence for estimating the relative age of taxa. It is widely agreed that diploid taxa, especially in montane or arctic regions, originated in the Tertiary with subsequent formation of polyploids in the Quaternary and up to recent times. Polyploidy is almost always an irreversible phenomenon, making it all the more important that the cytological status of populations should be known. Examples are known of taxa once regarded as recent endemics which have turned out on investigation to be diploid relics while major populations from which they were thought to have been derived are found to be polyploid and themselves derived.

Conditions in the Quaternary are likely to have favoured hybridization and intraspecific crossing of differently adapted populations or ecotypes, especially in montane habitats, with the consequent formation of allopolyploids. New habitats opened up by the glaciations allowed the establishment of these new polyploids and changed selection pressures would allow the further crystallization out of the polyploid derivatives. The

sequence of hybridization and polyploidy was probably followed, however, by subsequent hybridization between polyploid components with the result that the morphological gaps between the original taxa were filled.

Polyploidy is often, therefore, a cyclical phenomenon and the evidence from many cases seems to point to the desirability of considering polyploidy as a progressive condition that can arise within species or species-groups. It is, in Huxley's terminology, not simply cladogenesis but also anagenesis, although neither term quite applies. It was pointed out that in polyploid complexes such as *Dactylis glomerata*, *Phacelia magellanica*, etc., relationships are normally shown diagrammatically as anagenesis not cladogenesis. The implications of such a view of speciation by progressive polyploidy were discussed and it was suggested that in many such cases speciation had been polytopic and not monotopic as we have long been conditioned to think. If we looked for simple origins of species in many instances of polyploidy, it was probable we were asking the wrong questions.

The structure and dynamics of a typical angiospermous eupolyploid racial complex was demonstrated by F. Ehrendorfer (Vienna) using the example of the Mediterranean–European Section Lepto-Galium (Rubiaceae). Lepto-Galium consists of 6 series, corresponding to good Linnean species, and about 40 micro-species; its history must go back a considerable way into the Tertiary. Three special cases were chosen to bring out some important general evolutionary features of Lepto-Galium: (1) The closely related alpine groups of *Galium baldense* and *G. anisophyllum* have undergone quite a different course of evolution. The *G. baldense* group is represented mainly by diploids and only one tetraploid ($2x + 4x$); it is strongly depleted in biotypes and has a very disjunct distribution in or near unglaciated areas. *G. anisophyllum*, on the other hand, is represented mainly by polyploids ($4x + 6x + 8x$) with only a few diploids ($2x$) persisting, and one advanced local decaploid ($10x$). It is very polymorphic and has a continuous distribution with the diploids around unglaciated areas and the ascending polyploid series progressively in marginal to central glaciated areas. (2) Detailed cytotaxonomical analysis of Lepto-Galium races in north-eastern Central Europe and adjacent Scandinavia has revealed that what was formerly regarded as one species consists of a number of micro-species. The diploids of *G. cracoviense* on limestone rocks of the Cracovian Jura and *G. oelandicum* in open Alvar vegetation of the Island of Oeland are closely related. Furthermore, there is the diploid *G. suecicum* in grasslands and open pine forests with a disjunction between the north-east German plains and southern Sweden. A tetraploid extension of the southern *G. valdepilosum* has reached the warm open oak woodland of the Hartz Mountains and central Jylland. Finally, there is the widespread octoploid, *G. pumilum*, which has its main habitats in mixed acidophilous oak forests of Central Europe but was introduced with grass seed farther north. These races seem to represent remnants of four waves of post-glacial invasion into formerly glaciated territory. They obviously correspond to well-known phases of post-glacial vegetation-succession and may be reconstructed with the help of ploidy sequence, ecological requirements, and by taking into consideration the post-glacial palæogeography of the Baltic Sea area:

G. cracoviense → *G. oelandicum* ($2x$): ± 7500 B.C., cold tundra and grassland.
G. suecicum ($2x$): 7000–6000 B.C., open boreal pine woodland.
G. valdepilosum ($2x$–$4x$): 4000–3000 B.C., thermophilous oak woodland.
G. pumilum ($8x$): 2000 B.C. → present, mixed oak climax forest and adventitious.

(3) The origin of the relatively recent high polyploid *G. pumilum*, the most widely distributed microspecies of the section, can be linked to diploid and tetraploid relic groups of progenitors which to-day are found partly in south-eastern European refugial areas. In addition, there is ample evidence for hybridization on the octoploid level with other parallel polyploid lines (*G. rubrum*, *G. marchandii*, *G. anisophyllum*), resulting in further increase of variability and plasticity of *G. pumilum*. While the primitive diploids and tetraploids are found mainly in permanent rock, talus and grassland associations, the derived polyploids are concentrated in open climax forest and corresponding successional associations.

One may generally conclude that cytogenetical, morphological, chorological and ecological aspects of racial structure and evolution in Lepto-Galium are closely tied together. While basic divergent evolutionary differentiation occurs predominantly on the diploid level, polyploidy linked with intra- and inter-specific hybridization seems very important for the mobilization of genotypic plasticity blocked on the diploid level by various internal isolation factors. This blockade is overcome by the origin of hybridogenous and polymorphic polyploid daughter-races. From a morphological point of view, the diploids form a discrete racial basis while the polyploids build a diffuse racial superstructure. The diploids are depleted in biotypes, show less colonizing activity, are often left behind in refugial areas and have disjunct distribution patterns. The polyploids with an increasing biotype reservoir are aggressive, have re-colonized extensively glaciated areas and show continuous distribution patterns. The diploids have been conserved mainly in stable environments and in permanent 'marginal' associations where successional changes of soil and vegetation are checked by specific edaphic conditions. The polyploids, on the other hand, mainly originate and are dispersed as members of widely expanding 'central' climax associations and corresponding labile successional stages.

Dr. G. Haskell (Genetics Department, Scottish Horticultural Research Institute) discussed the relationships between the effects of glaciation in Great Britain and North America and the present distribution of the genus *Rubus* (*R. fruticosus* agg.). Particular emphasis was paid to the prevalence of polyploidy and apomixis in this successful genus. In Europe there are now only a few diploid, sexual primary species which are considered to have survived the last glaciation, *R. tomentosus* and *R. ulmifolius* alone being widespread. Of these only *R. ulmifolius* occurs in Britain and is more frequent in the south, its distribution decreasing north of the last glaciation boundary (very roughly a line from the Wash to the Bristol Channel). When the vice-county frequencies of the 344 contemporary British species, listed in Watson's *Hand-book*, are plotted, the centre of diversity is revealed as south-east England, and the highest frequencies are generally in the non-glaciated areas. It is possible, however, that nunataks occurred north of the glaciation line.

The life-cycle of a representative sexual genus, stable at the diploid level, was illustrated by *Ribes nigrum*, and a facultative apomictic Rosaceous genus by *Malus zumi* and *M. sieboldii*. Competition between apomictic and sexual cells was demonstrated with one or other type ultimately winning. Fertilization is necessary in *Malus* to form a sexual endosperm, even that of an apomictic embryo, although such an embryo receives no contribution from the pollen. This is recognized genetically in *Rubus* as pseudo-heterosis in the young maternal-like offspring, and depends on the pollen parent. Hence all apomictic *Rubus* are pseudogamous; that is, they require pollination by fertile pollen.

Diploid primary *Rubi*, although sexual, are either partially or completely self-incompatible. Hence following the glaciation, with the consequent paucity of pollinating agents and the infrequency of individual plants, there would be a reduction in the opportunity for cross-pollination in the species, leading to poor seed setting. As polyploidy usually overcomes incompatibility, and as diploid *Rubi* are known to produce unreduced gametes, there would be encouragement of any polyploids produced by these diploids. Although they would still require pollination they could then set self-seed. This would,

however, have led to gradual inbreeding depression, known in diploid and tetraploid *Rubi* (for example, *R. idaeus* [2*x*], Merton Thornless [4*x*]), so there would be selection for those polyploids able to maintain themselves as heterozygotes with the consequent hybrid vigour. In other words, the apomictic pseudogamous types with good pollen would be at a selective advantage.

The apomictic mechanism in *Rubus* may or may not involve crossing-over and recombination, namely, apospory and diplospory respectively. Hence variation, although somewhat limited, can still occur and selection since the time of the last glaciation has been able to act on these forms. Hence evolution has given rise to the numerous apomictic 'species' which have proved so adaptable in re-colonizing land once under the ice. It is known that some British species of apomictic *Rubi* are widely spread and constant breeding: these are the predominantly aposporous types. The unstable apomicts, often represented by clusters of related minor 'species' with limited and scarcer distribution, are those segregants of a more diplosporous nature.

The whole gamut of these polyploid apomictic *Rubi* must have a fairly limited original parentage from diploids failing to survive glaciation. This is indicated by pollen of all species so far tested (providing the pollen is fertile) being able to function on the stigmas of other species, regardless of which of the 5 sub-genera they belong to. Furthermore, most of these apomicts are still facultative sexuals, so providing increased adaptability.

Finally, although polyploid apomictic *Rubi* were at an advantage compared with sexual diploids following the last ice age, some tetraploid species, for example, *R. rosa* (4*x*) from North America, are now regularly producing secondary diploids, which are as vigorous as their tetraploid sibs. Attempts are now being made to extract diploids from the highly apomictic *R. caesius* (4*x*), believed from its cytology to be allotetraploid. In this way it is hoped to expose the original diploid parental species, which must have failed to survive glaciation, but which have been maintained biologically intact through the aposporous mechanism for thousands of years.

During the discussion which ensued it was very clear that mechanisms through which speciation occurred differed markedly in animals and in plants. Polyploidy and apomixis had clearly played an extremely important part in the development of the vigorously colonizing plant species in post-glacial times, whereas neither process is suspected to have occurred to the same effect in the animal stocks concerned. Polyploidy and chromosome complications in insects, mentioned by both Prof. Zeuner and Mr. Higgins, seem to have been adapted to a different evolutionary purpose. Yet, surprisingly, the distribution patterns shown by the active post-Tertiary migrants, whether of animals or plants, had many points in common. It seemed that the environmental control called for a similar response, and this was supplied regardless of the mechanism concerned.

NUCLEAR MAGNETIC RESONANCE IN MOLECULES OF MODERATE AND HIGH MOLECULAR WEIGHT

THE third series of talks on magnetic resonance organized by the Department of Chemical Technology, Bradford Institute of Technology, was held during April 25–26. This year the title was "Nuclear Magnetic Resonance in Molecules of Moderate and High Molecular Weight". About seventy graduates attended from universities, colleges of advanced technology, Government establishments, and industry.

Opening the meeting, Dr. E. G. Edwards, principal of Bradford Institute of Technology, pointed to the number of academic institutions and of branches of the chemical industry represented—including colloids, fibres, organic chemicals, paper, petroleum, plastics, resins, rubber and soap—as some commentary on the wide acceptance of nuclear magnetic resonance in academic and industrial research. Nuclear magnetic resonance spectrometer manufacturers also sent representatives: three from the United Kingdom and others from Japan, Switzerland and the United States.

In his introductory talk, Dr. D. W. Jones (Bradford Institute of Technology) summarized the magnetic properties of nuclei which underlie nuclear magnetic resonance spectroscopy and showed how the chemical applications arise from interactions between the resonating nucleus and its magnetic environment—whether of the order of gauss in, for example, a solid polymer, or of milligauss in a liquid sample. As molecular size increases, the high-resolution spectrum does not invariably become complicated—for example, the phosphorus-31 spectra of some organic phosphorus compounds—but proton spectra of large molecules usually are complicated and low solubility or high viscosity may provide further problems. Such spectra with overlapping fine structure can often be unravelled with the aid[1] of high laboratory magnetic fields, integration of peak areas, and the double resonance technique.

In addition to the spectrometer components which have their analogues in more familiar regions of the electromagnetic spectrum, nuclear magnetic resonance needs a magnetic field of high intensity, homogeneity and stability. Dr. R. Freeman (National Physical Laboratory) first dealt with these requirements in his talk on experimental methods, and then outlined the radio-frequency bridge and crossed-coil systems as means of achieving minimal effective transmitter noise in steady state nuclear magnetic resonance experiments. With signals several kc/s broad, genuine nuclear magnetic resonance signals could be emphasized by modulating the field over a narrow band to yield a differential curve on sweeping. With liquid lines less than 1 c/s broad, the first pair of side bands produced by putting an audio-frequency of low modulation index on the resonant frequency of, say, 60 Mc/s has been used for calibration, base-line stabilization and control of field/frequency ratio. Finally, Dr. Freeman showed that it was feasible to use modulation techniques to achieve spin–spin decoupling[2] (frequency sweeping[3] one radio-frequency) and to observe the spin coupling effects on hydrogen-1 of carbon-13 in, for example, acetic acid molecules in which one of the two carbon nuclei is a magnetic isotope.

The second session was devoted to more detailed treatments of—chiefly high-resolution—nuclear magnetic resonance in various branches of chemistry. Dr. J. A. S. Smith (University of Leeds) opened his review of inorganic applications with a reference to susceptibility measurements of liquids by nuclear magnetic resonance, as first suggested by Feher and Knight and more recently by Frei and Bernstein[4], a topic which attracted attention in the subsequent discussion with regard to the validity of the calculations to samples in close contact. A variety of problems, including general stereochemistry, detailed bonding, and exchange processes, was described, starting with hydrido-complexes in which direct hydrogen-1-metal bonds are characterized by a proton peak of very high τ-value. The metal alkyls exemplify the use of both of the commonly measured nuclear magnetic resonance high-resolution parameters: coupling of the magnetic platinum-195 nucleus in aqueous trimethylplatinum nitrate[5], for example, gives a 77·3-c/s doublet across the methyl singlet corresponding to platinum nuclei with zero spin; while chemical shifts between methylene and methyl protons in X–CH_2–CH_3 compounds have been correlated with electronegativity. Among π-complexes, such as Zeise's salt and *cyclo*pentadienyl complexes, Dr. Smith showed that a comparatively simple hydrogen-1 resonance criterion can sometimes give a useful structural indication. Most of the talk dealt with diamagnetics, but mention was made of some paramagnetic complexes in solution, for example, the nickel (II) aminotroponeiminates, in which the relaxation times permit quite well-resolved high-resolution hydrogen-1 spectra to be recorded, from which spin densities have been deduced[6].

Speaking about applications to organic structure determination, Dr. A. R. Katritzky (University of Cambridge; professor designate, University of East Anglia) first showed how phosphorus-31 resonance in monothiopyrophosphates can give a simple proof of the symmetry of a product. He then concentrated on hydrogen resonance in a limited range of nitrogen heterocyclic compounds of fairly low molecular weight, starting with the information that τ-values and multiplicities can give about disulphonylaminopyridines. Dr. Katritzky directed attention to the effects of tautomeric rates on nuclear magnetic resonance spectra and to the importance of interpreting these spectra in conjunction with those from the infra-red and ultra-violet, instancing 3,4-dimethyl-Δ^3-pyrrol-2-one and related compounds[7]. Finally, Dr. Katritzky showed how the rapid molecular rearrangement of benzofuroxan manifests itself in proton resonance as a change from an unsymmetrical $ABCD$ spectrum at low temperatures to a symmetrical A_2B_2 spectrum at 130° C (ref. 8).

Polymers have been investigated by both broad-line and high-resolution nuclear magnetic resonance techniques. Dr. I. M. Ward (Imperial Chemical Industries, Ltd., Fibres Division) first discussed the measurement over a temperature range of the width, second moment, and relaxation times of comparatively broad polymer lines, which can often lead to information about the motion of the structure and to a nuclear magnetic resonance parameter related to crystallinity. A molecular interpretation of the nuclear magnetic resonance transitions tends to be more readily obtained for the main glass transition than for processes at lower temperatures. With polypropylene as an example[9], the advantages of making measurements on a number of deuterated samples and of correlating nuclear magnetic resonance and dynamic mechanical data were outlined. The same polymer was used to illustrate the desirability of being able to interpret high-resolution spectra of polymers in solution in terms of local stereochemistry and so predict stereoregularity in the bulk of the polymer. However, undeuterated vinyl polymers are liable to give overlapping spectra complicated by coupling from protons on the α-carbon[10]; most published nuclear magnetic resonance investigations of stereoregularity have been on more amenable polymers, such as polymethyl methacrylate or deuterated polypropylene.

In the concluding session, several manufacturers described the potentialities of commercial nuclear magnetic resonance spectrometers. Mr. J. M. Babb (Varian AG) outlined equipments extending from a 2–16-Mc/s variable frequency broad-line instrument through the 60-Mc/s analytical spectrometer to the 100-Mc/s system; Dr. I. Stelzer (Delviljem, Ltd.) presented the less-familiar but almost equally extensive Japan Electron Optics range; and Mr. H. J. M. Fitches (Associated Electrical Industries, Ltd.) discussed a British spectrometer based on a 14,000 gauss electromagnet and capable of resonating at various frequencies. Among permanent magnet high-resolution spectrometers, Mr. L. Minikin (Mullard Equipment, Ltd.) described a relatively cheap 9,000 gauss instrument intended for proton resonance, and Mr. L. K. Parker (Perkin-Elmer, Ltd.) introduced a 14,000 gauss instrument designed to operate at the frequencies of several nuclei either separately or for spin decoupling.

SHRINKPROOFING WOOL

A COLLOQUIUM on shrinkproofing sponsored by the Commonwealth Scientific and Industrial Research Organization and the University of New South Wales was held on March 13 at the Organization's Division of Textile Physics, Sydney. This was the third in the series of wool research colloquia which the C.S.I.R.O. initiated in 1961; the first two dealt with the structure of wool and the setting of wool respectively. Prof. J. B. Speakman, of the University of Leeds, gave the opening address. Only three formal papers were presented and, in addition to discussion periods associated with the papers, an entire session was reserved for informal contributions from the sixty invited delegates.

Prof. Speakman dealt with the three main methods of obtaining shrink-resistance in wool fabrics—cross-linking, resin deposition and chemical degradation. He pointed out that the last method, the most commonly used, was least satisfactory in its effect on other important fabric properties such as resistance to wear. No major advance had been made in the theoretical understanding of this approach in the twenty-five years since the suggestion was put forward that the only necessary reaction was rupture of disulphide bonds. The optimum result was obtained when this reaction was confined as much as possible to the surface layers of the fibres, to produce modification of the scales. Recently, processes of this type had been adapted for continuous treatment combined with continuous dyeing.

The other approach to surface modification was to mask the scales by depositing resin. Such a treatment could be used to improve resistance to wear and resistance to

creasing of wool fabrics at the same time as it conferred shrink-resistance. Combined in the one process, these effects would enable development of easy-care tropical worsted fabrics. For a given weight of polymer, the optimum benefits in both shrink-resistance and abrasion-resistance would be obtained only if the resin were polymerized by a method which at the same time anchored it chemically to the fibres.

Prof. Speakman suggested that cross-linking had the greatest potential as a shrinkproofing technique. No industrial process of this type had been developed, and this was due to lack of knowledge of the distribution of the reactive side-chains in keratin. Moreover, in past investigations insufficient attention had been given to the ratio of the amount of cross-linking reagent to the amount of wool. Unless this was strictly controlled, optimum cross-linking might not be obtained. If these problems were overcome, a process could be developed which would be satisfactory for all end-uses except those requiring crease-resistance.

Dr. E. F. Denby and Dr. M. W. Andrews (C.S.I.R.O.) reported progress in analysing fibre movement during washing of untreated fabric and fabric shrinkproofed with the C.S.I.R.O. potassium permanganate/saturated sodium chloride process. They claimed that the direct effect of washing was fibre movement and showed that the treatment caused a reduction in the rate of fibre movement. For a given level of treatment this rate was constant up to at least 10 per cent linear shrinkage. Thus there was considerable fibre movement during the induction period (the period at the commencement of washing when no shrinkage occurs). The relation between shrinkage and the average fibre movement was independent of the level of the treatment. This indicated that the mechanism of felting was the same in the treated and untreated fabrics.

The force required to move the fibres during washing depended on their elastic properties, their frictional properties and the distribution and pressure of inter-fibre contacts. Average values of this force were obtained by pulling fibres from the fabric in the against-scale and with-scale directions. The against-scale force for the treated fabric was considerably less than the value for the untreated fabric, whereas the with-scale force was only slightly altered by the treatment. The force was also altered by washing the fabric. A significant increase in the against-scale force occurred during the induction period. It was suggested that this increase was due to changes in the surface of the fibres brought about by the mechanical effect of the washing, and that an increase in the with-scale force, which was observed at the end of the induction period, might be associated with the formation of 'entanglements' of the type suggested by Shorter.

Developments and progress in shrinkproofing were reviewed by Dr. J. R. McPhee (C.S.I.R.O.). He suggested that research into the chemical degradation methods should be directed towards making simpler and cheaper processes, keeping in mind the disadvantages that still existed in processes of this type. Although resin treatments appeared to offer genuine advantages, these advantages tended to be outweighed in practice because the cost and complexity were high. The most promising was the formation of polyamides on the fibre surface by a technique called 'interfacial polymerization'.

The informal discussion period was led by Prof. A. Datyner (University of New South Wales) and Dr. A. J. Farnworth (Australian Wool Bureau), who briefly discussed problems and anomalies encountered in shrinkproofing research. The main impression gained from this discussion period was of wide gaps in basic knowledge. At present many phenomena have not been explained, and in some cases sound basic ideas have not been developed to the stage required for industrial use. Dr. Farnworth listed several instances; for example, the efficiency of the simple oxidation processes would be considerably increased if the reaction could be restricted entirely to those chemical sites the modification of which is essential for changes in the frictional properties of the fibres; however, little is known about these sites. Delegates reported that the effect of surface contaminants on the efficiency of many processes is not fully understood; nor did they know how to explain the pattern in which *p*H, temperature, etc., of the felting media affect felting rates. Above all, there is very little information about what happens physically in a fabric during felting.

To conclude on this note would be to deny the sound progress made in this field. The manufacturer has now come to a realistic appreciation of the need for careful quality control. Dr. McPhee reported that there are at least six processes in common use producing good results for a wide variety of applications; several of these processes do not impair the 'handle' of the wool. Thus the textile chemist has disdained the luxury of inactively waiting for basic research to point the way to the process *ne plus ultra*.

M. W. Andrews

ENERGY AND THE EUROPEAN ECONOMIC COMMUNITY

A BROADSHEET written by J. Hartshorn, entitled *An Energy Policy for E.E.C.*, and issued by Political and Economic Planning*, reviews briefly the national energy policies of Belgium, France, Western Germany, Italy, Luxembourg, the Netherlands and the United Kingdom, the search of the European Economic Community for a co-ordinated energy policy up to the 1962 proposals for a common market in energy, and finally considers the prospects for a policy.

While during the past three years the concepts on which a logical and coherent policy might be based have been steadily refined, there is no certainty that the member nations can be brought to accept one. Nobody, even coal interests, expects to be able to expand domestic fuel-producing capacity and productivity enough to keep pace with the growth of energy requirements to the extent that, for example, European farm interests can confidently be hoped to expand in domestic farm products. Energy demand per head shows less sign of levelling off within rising standards of living than food demand does.

The French have some objections of principle to the concept of an open common market in energy, and are not convinced that this is the surest way of arriving at the lowest energy costs if that means giving the non-European oil companies free play at a time when the Community's energy resources are on the point of being used up. Reliance on the diversification of sources of oil supply is a real safeguard, but its importance can be exaggerated. Diversification may raise the question of possible preference to particular oil-producing areas. In the context of scarcity, the 4–6 month level of supplies suggested for stocks by the European Economic Community has much logic, but may not be cheap even if it supplies sufficient insurance against the interruption of Soviet supplies as well.

Apart from the vested interests of the European nations concerned, Mr. Hartshorn sees cogent arguments for delay, and points out that it is difficult not to share some

* *Planning*, Vol. 29. No. 469 (18th March, 1963). *An Energy Policy for E.E.C.* By Jack Hartshorn. Pp. 55–98. (London: Political and Economic Planning, 1963.)

of the reservations of the Governments asked to commit themselves to these oil policies. An oil policy for Europe fitting the provisions of the Treaty of Rome and a coal policy fitting a possibly revised Treaty of Paris could exist, but he hesitates to suggest that this will be the outcome. What is remarkable, moreover, is the almost complete absence in the Broadsheet of any reference to nuclear energy.

PETROLEUM IN 1975

ON April 27, 1963, Esso Petroleum Co., Ltd., celebrated its seventy-fifth anniversary and a special issue of the *Esso Magazine* was published to mark this milestone in the Company's history.

The leading article, entitled "A Look Ahead to 1975", makes some interesting forecasts for the petroleum industry in Britain. If world economic progress during the next twelve years continues at the same rate as in the past twelve years, it is estimated that world oil demand will rise from the 1962 figure of 1,200 million tons to 2,200 million tons in 1975; in Britain the demand will approximately double the 1962 figure of 52 million tons to 102 million tons by 1975. New sources of oil may stem from the discovery of large natural gas deposits in Holland in 1961 and this has inspired an under-water search for oil off the British coast in the North Sea, a joint venture by Esso, Shell and British Petroleum. Esso is at present exploring possibilities in Kent, Sussex and Hampshire.

In the matter of transporting crude oil from overseas to refineries in Britain, tankers of 26,000 tons d.w. were among the largest afloat in the 1950's; now 80,000-ton tankers are already a feature of the Esso fleet and an 86,000-ton ship is scheduled for service early next year. The economic advantages of tankers up to 150,000 tons d.w. are at present under consideration, and the possibility of nuclear-powered tankers being used by 1975 is by no means remote.

If the forecast of demand for petroleum products doubling itself in the next twelve years is correct, then Britain's refining capacity will have to be increased to take care of at least another 50 million tons of oil by 1975, involving a capital outlay in the region of £200 million. In the distribution of refined products, pipe-lines are destined to play an increasingly important part in the years ahead; it is estimated that by 1975 about two-thirds of the 'white' products marketed by Esso alone in south-east England and the Midlands will travel by pipe-lines.

Fuels for engines of all kinds, ships' bunkers, cars, lorries, locomotives, aviation fuels, etc., are expected to increase the demand by 75 per cent, oils for heating about 70 per cent greater in 1975 than in 1962. Regarding heavy oils for industry, apart from traditional fuels, new methods of generating electricity are anticipated by 1975, such as magnetohydrodynamics, which converts the energy into hot gases, produced by burning fuel, directly into electricity in a strong magnetic field; the fuel cell would convert petroleum products into energy at a much higher efficiency than 45 per cent, the maximum efficiency that at present is achieved in the modern power station. Finally, the capital expenditure in Britain to cover all these developments in the oil industry is anticipated to be more than £1,000 million during the next twelve years.

H. B. MILNER

PRE-FLUVIAL, AUTOGEOSYNCLINAL SEDIMENTATION IN THE NAMURIAN OF THE SOUTHERN CENTRAL PROVINCE

By B. K. HOLDSWORTH

Department of Geology, University of Keele

SINCE the publication of Gilligan's[1] now classic study, British stratigraphers have stressed the deltaic and terrestrial aspect of Namurian rocks developed in the Central Province of England—'The Millstone Grit Series'.

While coarse, cross-bedded arkosic sandstones—the 'fluvial grit facies' of Trotter[2]—such as those investigated by Gilligan undoubtedly record terrestrial, fluvial activity (cf. ref. 3) and represent an important stage in the evolution of the Central Province, it has long been realized that in the south of the Province a complex history of Upper Carboniferous sedimentation preceded the first appearance of fluvial conditions[4–6]. An important newly published account of Carboniferous rocks in the Ashover district[7] together with earlier work in the Staffordshire–Derbyshire region and recent investigations in north Staffordshire and south-west Derbyshire allows the period between the close of the Dinantian and the first establishment of fluvial environments in the region to be seen in clearer perspective.

Hudson and Cotton[8] stressed that Dinantian successions in the area are of two contrasting aspects—'basin' and 'massif'. The sedimentation contrast was apparently related to a northerly projection of the Carboniferous Central Land Barrier (St. George's Land). On the submerged surface of this projection from the ancient block developed the limestones of 'massif facies'. To the north and west lay the basin area.

During *D*1(*B*2) time a part of the western and northern margin of the block projection in Derbyshire became marked by a line of limestone-reef building activity. To-day the belt of 'reef-knolls' is almost completely exposed from the upper Dove Valley to the Castleton district. East and south of the belt in Derbyshire, back-reef, massif limestones are exposed (cf. refs. 9 and 10). West and north of the belt, in north Staffordshire and north Derbyshire respectively, borings show contemporaneous limestones and shales of basin aspect[8].

A slight increase in differential movement between the geotropically negative basin- and positive massif-areas probably explains the *D*1(*B*2) reef-building episode and it appears that this movement continued into *D*2 time[8]. By late *P* time, however, the positive tendency of the massif projection appears to have been lost and rather similar, relatively argillaceous limestones accumulated over earlier basin- and earlier massif-areas alike[8].

The framework which was to govern the distribution of sediment accumulation during some two-thirds of Namurian time now developed, probably in late *P* time, through recrudescence of differential movement between basin- and massif-regions. Uplift along the earlier reef-building line resulted in an essentially monoclinal fold. Erosion exposed the line of *D*1(*B*2) knolls and gave rise to the local *D*1(*B*2)–*E*2 (Namurian) unconformity at the massif margin in north Derbyshire[11] and the upper Dove Valley[8].

The re-establishment of a positive tendency in the massif exerted a profound control on Namurian sediment accumulation. Contrast between thick earlier Namurian

successions of the basin area and the diminished accumulations of the massif is marked. Differential subsidence was now apparently greater than at any point in Dinantian time and the area of Staffordshire–Derbyshire west and north of the massif margin possessed the essential properties of an 'autogeosyncline' in the sense of Kay[12]. Only when the period of autogeosynclinal subsidence ended in approximately late Kinderscoutian (*R*1) time did fluvial grit environments become established in the Staffordshire–Derbyshire region.

Six established successions of Namurian rocks (Fig. 1) serve to illustrate thickness differences between: (*a*) massif —Eakring[13] and Ashover[7]; (*b*) autogeosyncline margin— upper Dove Valley; (*c*) points within the area of major subsidence—Morridge-Goyt area (in part from Cope[14]), Gun Hill[8] and Alport region[15].

Three phases may usefully be distinguished in the *E*1–*R*2 history of the autogeosynclinal basin.

The first phase is roughly co-extensive with the Pendleian Stage (*E*1). 600 ft. of beds were deposited at Alport, 800 ft. at Gun Hill and at least 400 ft. in the Morridge region, where the base is as yet unknown. Some 40 ft. only comprise the Stage at Ashover.

The phase appears to have been one of marine, restricted circulation conditions over the entire Staffordshire–Derbyshire region. The characteristic coarser sediments (that is, of silt grade and greater) of the basin are thinly bedded, fine calcareous sandstones and silt-stones. The petrography of these rocks at Alport and Gun Hill—known only from bore-hole specimens—was described by Hudson and Cotton[8,15] and the rock type termed 'crowstone'. Contemporaneous beds deposited closer to the basin margin and exposed in the Morridge area prove to be of uniformly finer grain, better laminated but essentially similar in detrital and secondary mineralogy.

Material preserved from the Alport and Gun Hill borings, re-examined with the permission of the Geological Survey of Great Britain, provides little evidence regarding depositional processes. The strongly laminated contemporaneous beds of the Morridge area, however, appear to be late-stage sediment differentiates of turbidity currents and it is highly probable that the majority of coarser Pendleian beds are of turbidity current origin. Siliceous spicules, endothyrid foraminifera and radiolarians contained in the beds suggest local, intrabasinal derivation of the sediment.

Scarcity of autochthonous faunas in the inter-turbidite shales and mudstones and absence of sole-trails suggest that layers of bottom water were probably toxic, highly charged with hydrogen sulphide, and acidic. Carbonates crystallized in abundance only, apparently, in response to slight rises in *p*H as bottom water was 'freshened' by turbidity current inflow. Conditions appear to have been equally inimical to life over the massif—a submarine 'high' unaffected by the turbidity flows of the basin[7].

Deposits of the second phase in the history of the autogeosyncline—Arnsbergian (*E*2) to early Kinderscoutian (*R*1)—are more variable both vertically and laterally. In the north Derbyshire region no coarser sediments accumulated, but sedimentation was still distinctly heavier than that over the massif area (Fig. 1). Subsidence may have been slightly less than during the first phase, and fossiliferous shales with goniatite–lamellibranch faunas and horizons of early diagenetic limestone point to at least periodic improvement in water circulation and aeration within the basin. A rather similar succession has recently been established at the basin margin in the Upper Dove Valley. Here the south-westerly directed marginal slope prevented the accumulation of the types of coarser sediments which were being deposited only some one and a half miles to the south-west in the north-east Morridge region and more heavily farther to the south and west in North Staffordshire (see, for example, ref. 16).

The fine and medium grained, relatively thin-bedded orthoquartzitic and protoquartzitic sandstones which characterize the second phase in north Staffordshire are essentially of Trotter's[2] 'grit-shale facies'. Traditionally (for example, refs. 4 and 17) the rock type has been known as 'crowstone' and contrasts strongly with the type characteristic of phase one and termed 'crowstone' by Hudson and Cotton[8,15].

Both thinness of bedding and absence of current bedding appear to reflect deposition of the sands in a still relatively rapidly subsiding area. Farther from the source and close to the margin of the basin in the north-east Morridge region units of coarser sediments are still more thinnly bedded and show many typical turbidite features. Sole structures clearly indicate transport from generally southerly points.

Episodes of grit-shale ('crowstone') and turbidite deposition probably occurred during periods of reduced salinity but good bottom aeration—as evidenced by abundant sole-trails. Much plant material in the marginal turbidite lithofacies and thin coals in the 'crowstones' (cf. ref. 17) point to a heavily vegetated southern land surface of low relief. Mineralogically the sands and silts are highly mature. Plagioclase feldspars occur in trace quantities only and potassium feldspar is absent. Garnet is very rare in heavy mineral fractions. The scarcity of unstable detrital minerals is believed to reflect extensive acidic alteration of material under the vegetation cover of the source area. The acme of proto-quartzite deposition in the Morridge area occurred during Chokierian (*H*1) time, corresponding with a brief appearance of swampy terrestrial conditions and shelly marine faunas (cf. ref. 18) at Congleton Edge, lying at the south-western margin of the autogeosynclinal area.

While the rapidly subsiding north Staffordshire region was receiving the highly modified coarser detritus of the

southern land surface and a relatively thick succession of marine shales and limestones was accumulating in north Derbyshire beyond the influence of the land area the massif-region persisted as a submarine high.

Sands of phase three—upper Kinderscoutian (*R*1) to lower Marsdenian (*R*2)—contrast markedly with the southerly derived phase two material. Potassium feldspar and biotite appear for the first time: plagioclase becomes more abundant and garnet very much more so. Sedimentary structures and thickness distribution suggest supply from northerly points and phase three sands appear to mark the first appearance in the Staffordshire–Derbyshire region of coarse, relatively unmodified detritus transported across the Central Province from the northern continent of crystalline rocks[1,3].

Early in the phase, subsidence was still sufficiently rapid to produce a typical turbidite lithofacies in north Derbyshire[19]. Slightly later the massif margin in south-west Derbyshire underwent burial by sub-arkosic sands of 'grit shale facies' but farther east the massif-area probably preserved a positive tendency and no coarser sediments accumulated[7,13]. Late in the Kinderscoutian, fluvial conditions were established in north Derbyshire. The separate histories of autogeosyncline and massif were now virtually at an end. The foundations had been laid for the Province-wide fluvial episodes of the upper Marsdenian and Yeadonian (*G*), and for the widespread paralic environments of the Westphalian.

I thank Prof. F. W. Cope, Dr. F. M. Broadhurst, Mr. T. G. Miller, Dr. W. H. C. Ramsbottom and the Leeds office of the Geological Survey of Great Britain for advice and assistance.

ACCURATE TIME FOR FIELD ASTRONOMY

By W. A. STEPEC
Department of Mining, Imperial College of Science and Technology, London

METHODS for the precise timing of optical observations have been investigated, and used for the determination of astronomical latitude, longitude and azimuth at any point in the field.

The most important aspect of the information gained is that the method developed is very accurate, can be used at any terrestrial station, requires little additional equipment, and is equally suited in all other cases where precise timing of optical observations is required, as, for example, in the optical tracking of satellites.

Observation signals and time pulses from a light-weight portable crystal chronometer built to specification by Messrs. Communication Systems, Ltd., together with all relevant field data, are recorded on magnetic tape, using a standard tape recorder, which has been found to be more accurate than a chronograph, and is also cheaper and more convenient.

Whereas conventional time signals and the seconds pulses on standard frequency transmissions are used for comparison of the time indicated by the crystal chronometer and for its calibration, their direct application as time supply in the field is dispensed with. This is because of the unpredictable reception conditions and periodical interruptions of signals and their transmissions at selected times only.

The working frequency of 16 657·006 c/s of the crystal chronometer is converted to give 61 pulses/min, of which 60 are audible as tone output of about 1,040 i.p.s., and one of 260 i.p.s., which is used to operate the minute clock and minute tone. A further output of 250 i.p.s. is provided as a marker signal which is operated by a key via a relay. The audible pulses are arranged at intervals of octaves from the standard pitch of $2^4 \times 16$ Hz. Recorded on tape at a speed of $7\frac{1}{2}$ in./s and played back at half or quarter of this speed all output tones are within the audible range of the human ear.

Three methods of timing were investigated, all of which could be used to compare the crystal chronometer pulses with time signals received by radio. Two of these methods could also be used to measure the time of an observation as indicated by the pulse produced by depression of the marker key.

In the first method pulses recorded at $7\frac{1}{2}$ in./s wore played back at quarter speed, and timed with a stop watch. The accuracy of time extraction achieved was approximately 0·03 sec.

In the second method the time vernier, arising from 61 sub-divisions of one minute as obtained from the crystal chronometer, and seconds pulses transmitted by radio, is used as a coincidence meter. The aural determination of the approximate coincidence of both audio signals, crystal chronometer and time reception, at slow re-play, achieved an average accuracy in calibration of the chronometer of about 0·02 sec.

Increased accuracy of time measurement was achieved using the third method. Magnetized impulses on the coated side of the magnetic tape are made temporarily or permanently visible with metallic powder suspended in volatile fluid (hydrocarbons) (Fig. 1). Thus the recorded time differences obtained from synchronization of the chronometer or from field observations are converted to measures of length. The sharply defined cycles of the visible pulses permit a scaling accuracy of 0·1 mm and better, even in the presence of radio noise. The mean square error of time-intervals thus extracted was of the order of 2×10^{-4} sec. The time vernier, which was originally introduced for the reason given here, is still essential when using the third method since the permanent overlapping of signals is avoided, the chance of error when scaling is reduced, and the use of a single track on the tape recorder is permitted. The duration and pitch of output tones of the crystal chronometer were specified to facilitate the identification of the visible signals. The characteristics of the pattern of pulses visible on the tape eliminate ambiguities that arise from transmissions that are almost synchronized.

Crystal Chronometer FAST on U.T.2 at $21^h\,07^m$, May 5, 1961: 1·115 sec. (ref. to R.G.O.)

Fig. 2

In Fig. 2 results are given of the reception of two separate sets of time signals from *MSF* (Rugby) and *HBN* (Switzerland), where the difference in the times of reception is given as 34·7 msec as measured in the field. The corresponding differences as calculated from published figures in *Bulletins* 56 and 32 of the Royal Greenwich Observatory, and the *Bulletin Horaire*, May 5, 1961, are 35·4 msec and 35·5 msec respectively, which agree with the field measurement within 0·7 msec. This and other measurements from the tape can be taken to this order of accuracy. The graphs in Fig. 2 show the results of time checks taken between radio time signals from *MSF* and *HBN* and crystal chronometer pulses. The mean difference was used to determine the discrepancy noted here. It will be seen that fluctuations, all less than 1 msec, are due mainly to tape distortion, scaling errors and reception conditions. The long-term performance of the crystal chronometer is much better, and if the chronometer is run in for 1 h before use then its rate is linear for a period of 6 h to an accuracy of ± 1 msec. Without voltage control, time comparisons before and after observations are required.

The theodolite used was a Watts 'Microptic No. 2', reading directly to 1 sec. The observation pulses were released manually at the instant a star or any heavenly body was crossing successively five calibrated grid lines engraved on the telescope's diaphragm, each subtending 30 sec. According to the star's parallactic angle these were either azimuth or altitude signals. The use of a five-line grid reduced the uncertainty of the mean square error of a single observation to 35 per cent. If the number of crossings is doubled, this would give only an additional reduction of 10 per cent and introduce optical errors. The grid diaphragm did not eliminate the personal equation, but enabled simultaneous measurements of vertical and horizontal angles to be taken. What is normally a complicated procedure was greatly simplified. Slow-moving stars were observed in the centre of the grid squares, eliminating the disturbing phenomenon of stars 'jumping the wire'. Telescope sights of transparent

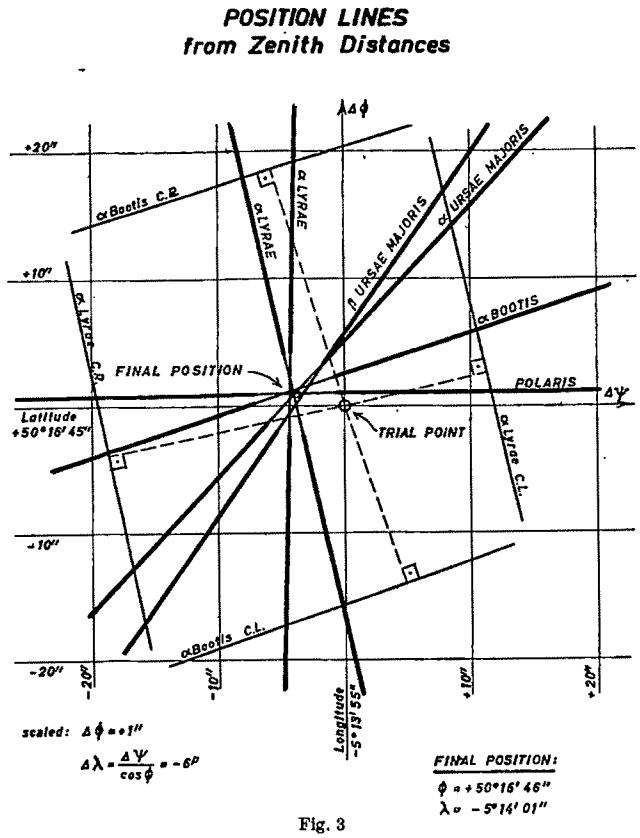

Fig. 3

synthetic resin, illuminated by the telescope lamp, were used for lining in the stars.

The personal equation and its error were determined by scaling on the tape the time intervals resulting from developed recorded mechanical chronometer clicks and marker pulses released at definite time readings indicated by the seconds hand of the mechanical chronometer.

Field results evaluated using the position line method based on zenith distances indicated that the mean of two C.L. and C.R. pointings to a single star with a single second theodolite is in error from the final adopted position by less than 1 sec (Fig. 3). The Laplace condition equation was satisfied where applicable.

The advantages of this method are as follows: Observational speed is raised so that two compensated measures of simultaneous altitude and azimuth can be taken to any visible star without the help of an assistant within 3–4 min, each observation consisting of five timed transits. The same precision can be obtained from fast-moving as from slow-moving stars (that is ignoring the personal error). The preparation of a star programme is unnecessary; star identification is easy. The chronometer error is reduced to such an extent that the only timing error of importance is the personal error. The cost of the crystal chronometer and recording equipment is moderate, being in the neighbourhood of £200.

Improvement in timing accuracy, to an extent worthwhile considering, cannot be expected with the use of an impersonal micrometer but may be possible by using some method of automatic recording of the star's transit, such as photoelectric registration.

The work was carried out at the Imperial College Field Station, Tywarnhale Mine, Cornwall. Initial trials were started in April 1959.

TESSERAL HARMONICS IN THE GEOPOTENTIAL

By IMRE G. IZSAK

Smithsonian Astrophysical Observatory and Harvard College Observatory, Cambridge, Mass.

A DETAILED investigation of the gravitational field of the Earth by analysing the motion of satellites is one of the major projects at the Smithsonian Astrophysical Observatory. The problem consists in the determination of the small numerical coefficients C_{nm} and S_{nm} in the development:

$$U=\frac{\mu}{r}\left\{1+\sum_{n=2}^{\infty}\left(\frac{a_E}{r}\right)^n\sum_{m=0}^{n}[C_{nm}\cos m\lambda+S_{nm}\sin m\lambda]\,P_{nm}(\sin\varphi)\right\}$$

of the force function of the Earth into a series of spherical harmonics; the adopted definition of the Legendre associated functions is:

$$P_{nm}(x)=(1-x^2)^{m/2}d^mP_n(x)/dx^m$$

The aim is to solve an inverse problem in celestial mechanics: Given the motion of objects in a gravitational field, derive the latter. Of course one has first to solve the direct problem—to construct an adequate orbital theory. Let us assume here that this has been done. Then we have analytical expressions for the perturbations caused by the several terms in the foregoing expansion which are functions of the geophysical constants C_{nm} and S_{nm}. Let us further assume that by some means or other we have succeeded in accounting for the most significant part of the dynamical effect of atmospheric drag, solar radiation pressure and for the perturbations by the Moon and the Sun. Then precise observations of satellites permit us to derive the coefficients of the spherical harmonics.

Many authors[1,2] have in this way computed the coefficients $C_{n0}=-J_n$, $S_{n0}=0$ of quite a few zonal harmonics. Such terms are of no concern to us here, because their primary effect is to cause secular and long-periodic perturbations in the orbital elements, easily separable from the perturbations caused by tesseral ($m\neq 0$) and sectorial ($m=n$) harmonics, the periods of which are sub-multiples of a day.

The satellite results[3–7] on tesseral harmonics published so far are contradictory and unreliable, mainly for two reasons. First of all, the observational material at the investigators' disposal was insufficient. Secondly, the adopted computational schemes were too simple. It might be some time before one can arrive at definite conclusions regarding the longitudinal dependence of the Earth's external gravity field. But there should not be any doubt about artificial satellites with a variety of orbital elements being the best means to achieve this goal.

Since last October the Smithsonian Observatory has been using a new IBM-7090 computer programme to analyse precisely reduced Baker–Nunn observations of several satellites. The input consists of the along-track and across-track residuals[8] of observations which we were unable to account for by known perturbative forces except that of tesseral harmonics. They also contain the effect of small errors in the station co-ordinates, and are about 15″ on the average. The accuracy of the observations is 2″ in position and 0·001^s in time. Because the residuals are linear in the unknown coefficients C_{nm} and S_{nm}, it is in principle a straightforward matter to compute the first few of them by the method of least squares. In practice,

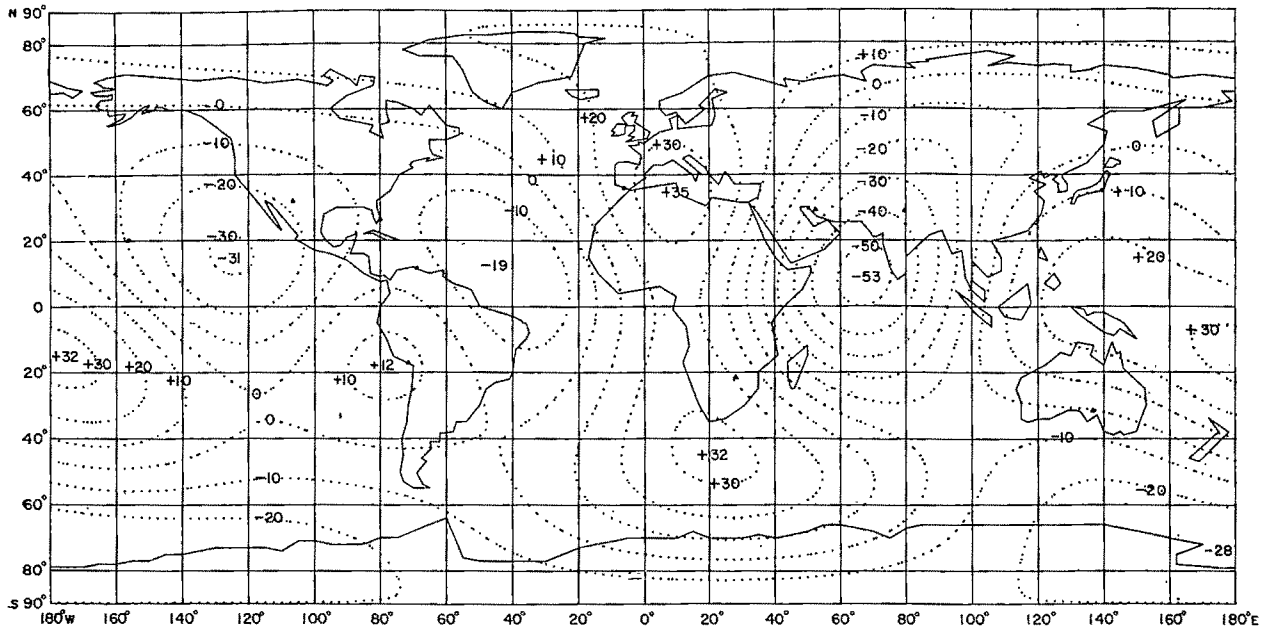

Fig. 1. Level curves of satellite–geoid heights at 10-m intervals. The small triangles indicate the positions of the 12 Baker–Nunn stations

however, one faces a rather difficult problem of data analysis. The residuals, especially those in the along-track direction, are by no means uniquely determined, because of the very nature of the differential orbit improvement which produced them. One usually gets different residuals for the same observation if two overlapping arcs of the orbit are fitted to it. For this and some other reasons, special care is necessary in this very tedious phase of the work. Then the distribution of a relatively small number of observations with respect to the arguments of the trigonometric functions that describe the perturbations is far from being uniform. Worst of all, the effect of the different tesseral harmonics is not very much different in size, and for some terms not even in shape. Therefore the perturbations caused by the various tesseral harmonics are hard to separate, a circumstance borne out by eventually considerable correlations among the unknowns. The only, but apparently rather efficacious, remedy for these difficulties seems to be the use of a large number of observations of satellites with a variety of orbital elements, with different inclinations in particular.

In selecting the observational material to be analysed one is limited not only by availability but also by what one considers an excessive machine-time needed for the execution of the computations.

Table 1 gives a short list of the observations we have been recently using.

Table 1. Observational Material

Satellite	i	e	a	Observations
1959 α1—*Vanguard* 2	32·9°	0·165	8·301 *Mm*	2,066
1959 η—*Vanguard* 3	33·4°	0·189	8·496 *Mm*	2,223
1961 δ1—*Explorer* 9	38·9°	0·115	7·985 *Mm*	2,629
1960 ι2—*Echo* 1, rocket	47·2°	0·012	7·972 *Mm*	1,465
1961 $\alpha\delta$1—*Midas* 4	95·9°	0·011	10·005 *Mm*	879

This material has been subjected to a variety of numerical experiments in order to obtain a feeling for the behaviour of the intricate least-squares process under discussion. Thus tesseral harmonics coefficients have been computed in different combinations; for example, C_{22} and S_{22} only; or C_{22}, S_{22} and C_{31}, S_{31}; or all sixteen of them, from the 2nd to the 4th degree. Furthermore, the observational material was divided into parts according, for example, to the individual satellites, to see how well the unknowns are determined by a smaller number of observations. We have been experimenting with weighting the observations in ways that seemed reasonable to us. In addition, the same programme can also compute corrections to the station co-ordinates. We have investigated their influence on the tesseral harmonics coefficients. Details concerning the outcome of such experiments would scarcely be of general interest. Suffice it to say that they made us more confident of the results than one could be without having carried them out. One of the latest runs of the programme gave the results shown in Table 2.

Table 2

$C_{22}=$	$9{\cdot}68\times10^{-7}$	$C_{41}=$	$-2{\cdot}88\times10^{-7}$
$S_{22}=$	$-4{\cdot}00\times10^{-7}$	$S_{41}=$	$-3{\cdot}21\times10^{-7}$
$C_{31}=$	$1{\cdot}12\times10^{-6}$	$C_{42}=$	$3{\cdot}51\times10^{-8}$
$S_{31}=$	$6{\cdot}16\times10^{-8}$	$S_{42}=$	$1{\cdot}23\times10^{-7}$
$C_{32}=$	$9{\cdot}12\times10^{-8}$	$C_{43}=$	$2{\cdot}15\times10^{-8}$
$S_{32}=$	$-1{\cdot}83\times10^{-7}$	$S_{43}=$	$1{\cdot}48\times10^{-8}$
$C_{33}=$	$7{\cdot}17\times10^{-8}$	$C_{44}=$	$9{\cdot}72\times10^{-9}$
$S_{33}=$	$1{\cdot}24\times10^{-7}$	$S_{44}=$	$1{\cdot}63\times10^{-8}$

The computed standard errors are unrealistically small, ranging from 3 to 15 per cent. The correlation coefficients of the 22- and 42-terms are extremely high, about 0·85; otherwise, one finds a few correlation coefficients to be about 0·20, the rest being less than 0·10. Including more objects with high inclinations in the analysis would undoubtedly make these coefficients smaller.

I believe that in consequence of the least-squares approach to the representation of the Earth's external gravity field, the individual coefficients C_{nm} and S_{nm} are not very meaningful in themselves; they should rather be considered a set. In other words, in comparing different solutions one should consider the combined contribution of the spherical harmonics to the force function U. A convenient way of doing this is to compute satellite–geoid heights. By satellite–geoid I mean an equipotential surface of the geopotential:

$$\Psi = U + \tfrac{1}{2}\omega^2(x^2+y^2)$$

as revealed by the motion of artificial satellites. Consider an approximate geopotential, $\tilde{\Psi}$, the equipotential surface $\tilde{\Psi}=C$ of which is a spheroidal Earth[9]. A suitable choice of the latter's flattening makes the finite and first-order part of $\tilde{\Psi}$ to coincide with that of Ψ. Then satellite–geoid height is the second-order positive or negative elevation of the equipotential surface $\Psi=C$ relative to the chosen spheroid.

A programme has been developed to compute, from a set of spherical harmonics coefficients, the level curves of geoid heights and gravity anomalies. Fig. 1, obtained on an EAI data-plotter, shows the level curves of satellite–geoid heights at 10-m intervals for the foregoing set of tesseral harmonics coefficients. The coefficients of the zonal harmonics are those given by Kozai[1]. Despite considerable differences in the individual coefficients these level curves compare favourably with results obtained by Jeffreys[10] and Uotila[11], based on surface-gravity data. The agreement of the new coefficients is best with the results of Kaula[12].

I thank Dr. Y. Kozai, Mrs. Gladys D. Johnson, Messrs. E. M. Gaposchkin and W. L. Joughin for help with this work, which was supported in part by grant *NsG* 87-60 from the National Aeronautics and Space Administration.

OPTICAL ROTATORY POWER OF THE POLYPEPTIDE α-HELIX: A RECONSIDERATION OF THE MOFFITT THEORY

By Dr. S. F. MASON
Department of Chemistry, University of Exeter

IN 1956, Moffitt[1] analysed the optical rotatory power of macromolecules composed of helically arranged chromophores by means of coupled oscillator theory, in connexion with the alteration in optical rotation and rotatory dispersion observed[2,3] when polypeptides change from the random-coil to the α-helix conformation. The theory, predicting an abnormal rotatory dispersion for the α-helix conformation, was found[4] to be in quantitative agreement with the data then available, but shortly afterwards Moffitt, Fitts and Kirkwood[5] discovered that, owing to the use of cyclic boundary conditions, important terms contributing to the rotatory power of the α-helix had been neglected in the previous treatment. The additional and the original terms appeared to be of comparable magnitudes, and these authors suggested[5] that the agreement between Moffitt's theory[1] and experiment[4] was illusory. However, subsequent experimental work[6–9] supports further predictions of Moffitt's original theory[1], and it is now shown that the later treatment[5] does not alter significantly the conclusions of that theory.

Moffitt considered[1] a helix composed of N amide residues, and he showed that of the N possible electronic transitions corresponding to a particular amide chromophore excitation only three were allowed. The quasi-symmetric coupling of the individual amide chromophore excitations gives a transition with moments directed along the axis of the helix (Fig. 1*a*), and two quasi-antisymmetric coupling modes give a degenerate transition with moments directed perpendicular to the helix axis (Fig. 1*b*). Each of the allowed transitions involves a helical displacement of charge, giving an electric and a magnetic dipole transition moment orientated along the particular polarization direction.

The optical rotatory power of an electronic transition in a dissymmetric molecule is governed by the rotational strength, R, which represents[10] the scalar product of the electric, ρ, and the magnetic, μ, transition moment, namely:

$$R = \rho\mu \cos\theta \qquad (1)$$

where θ is the angle between the directions of the two moments. The rotational strength of an electronic transition is given experimentally by the band area of the corresponding circular dichroism absorption, measured either as the differential extinction coefficient for right and left circularly polarized light ($\varepsilon_l - \varepsilon_r$), or as the molecular ellipticity [ψ].

For a right-handed helical polypeptide, and for a particular amide chromophore excitation with an electric moment, ρ, and a frequency, ν, the resultant rotational strengths, per residue, of the transitions polarized parallel and perpendicular to the helix axis, $R_{\parallel}$ and $R_{\perp}$, respectively, are given by[1]:

$$R_{\parallel} = -R_{\perp} = \pi\nu d\rho^2 \cos t \cos v \qquad (2)$$

where cos t and cos v are, respectively, the tangential and the vertical cosines of the transition moment vector in each individual amide chromophore, which lies at a radial distance, d, from the axis of the helix. The terms, tangential and vertical, refer to a cylindrical co-ordinate system, in which the outward radial vector, the tangential vector, and the vertical direction of the advancing screw, form a right-handed set of Cartesian axes (Fig. 2).

Peptides and other amides give broad $\pi \rightarrow \pi$ absorption bands[11,13] near 1900 and 1600 Å, with oscillator strengths, in the case of dimethylformamide[13], of 0·237 and 0·209, respectively. Studies of the crystal spectrum of myristamide, measured with plane-polarized light[13], indicate that the most probable orientation of the 1900 Å transition moment is at an angle of 9·1° to the nitrogen–oxygen direction, in the sense that a parallel line through the nitrogen atom cuts the carbonyl bond (Fig. 3). The α-helix[14] contains some 3·6 amide residues per unit turn, during which the helix, with a radius of 1·6 Å, rises through 5·4 Å. The disposition of a given amide group in the cylindrical co-ordinate system of a right-handed α-helix (Fig. 2) gives the direction of the transition moment responsible for the 1900 Å amide absorption radial,

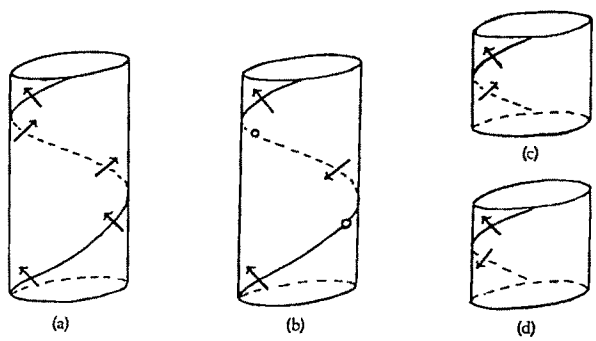

Fig. 1. The transition moments of the polypeptide α-helix giving the 1900 Å amide absorption due to: (*a*) the parallel, quasi-symmetric, coupling mode of the residue excitations; (*b*) one component of the doubly-degenerate, perpendicular, quasi-antisymmetric, coupling mode; (*c*) the quasi-symmetric coupling mode in a helical segment containing two amide residues; (*d*) the quasi-antisymmetric coupling mode in a two-residue segment

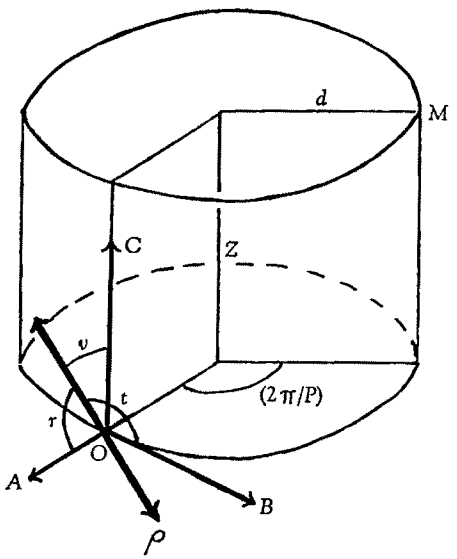

Fig. 2. The orientation of the moment vector, ρ, of the transition giving the 1900 Å absorption of an amide residue at O in the cylindrical co-ordinate system of the α-helix, defined by the radial, tangential, and vertical vectors, OA, OB and OC, respectively. The residue at M is related to that at O by the rise per residue along the helix axis, Z, the radius of the helix, d, and the angle about the helix axis $(2\pi/P)$, where P is the number of amide residues per unit turn of the helix

tangential, and vertical angles of some 90°, 140° and 50°, respectively.

For the corresponding absorption of the polypeptide α-helix, these values give the parallel-polarized transition the smaller oscillator strength and the lower frequency, Moffitt estimating[1] the energy separation, $\Delta\nu = \nu_{\parallel} - \nu_{\perp}$, to be —2,800 cm^{-1}. For the right-handed α-helix the degenerate perpendicular transition (Fig. 1*b*) should have a positive rotational strength with the value of $\sim 120 \times 10^{-40}$ c.g.s., while the parallel transition (Fig. 1*a*) should have a negative rotational strength of the same absolute magnitude. Since the parallel and the perpendicular transitions of the α-helix have a small energy separation and rotational strengths of equal magnitude and opposite sign, the two terms which they contribute to the expression for the molecular rotation give, when combined, an equation denoting an abnormal dependence of the rotation on the fourth power of the wave-length[1], namely:

$$[M']_\lambda = b_0\lambda_0^4/(\lambda^2 - \lambda_0^2)^2 \qquad (3)$$

where $[M']_\lambda$ is the contribution of the allowed transitions due to excitation-coupling in the α-helix to the molecular rotation per amide residue at the wave-length λ, and λ_0 is the average of the wave-length maxima of the absorption given by the transitions, b_0 being a constant.

The abnormal rotatory dispersion observed[4] for poly-L-glutamic acid and other polypeptides derived from L-amino-acids in solvents favouring the α-helix conformation give experimental values of $b_0 \simeq -640°$ and $\lambda_0 \simeq 2100$ Å for the constants of equation (3), compared with Moffitt's theoretical values[1], $b_0 = -580°$ and $\lambda_0 = 2000$ Å. The polarized absorption spectra[6] of orientated films of poly-L-alanine and poly-γ-methyl-L-glutamate place the absorptions due to the parallel and the perpendicular transitions of the α-helix at 2060 and 1910 Å, respectively, corresponding to an energy separation, $\Delta\nu = -2{,}700$ cm^{-1}, in agreement with Moffitt's theoretical value[1]. (A later, corrected, value is $\Delta\nu = -3{,}700$ cm^{-1}; Doty, P., and Holzwarth, G. M., private communication.) The spectrum of the α-helix form of poly-L-glutamic acid in aqueous solution[7] shows that the absorption due to the parallel transition appears as a shoulder at 2050 Å on the more intense band at 1900 Å due to the perpendicular transition (Fig. 4), supporting the theoretical oscillator-strength ratio for the two transitions.

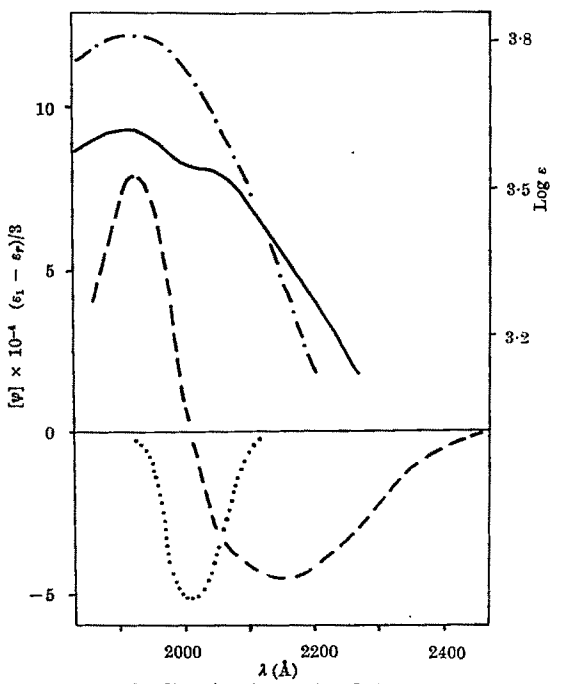

Fig. 4. The circular dichroism (– – – –) and the absorption spectrum (———) of the α-helix form of poly-L-glutamic acid, and the circular dichroism (· · · ·) and the absorption spectrum (—·—·—) of the random coil form (based on data recorded in refs. 7 and 8)

The corresponding spectrum measured with circularly polarized light[8] gives two circular dichroism absorptions with maxima at 2160 and 1920 Å (Fig. 4), and from the areas of the circular dichroism bands the rotational strengths of the parallel and the perpendicular transitions of poly-L-glutamic acid in the α-helix conformation are estimated[8] to be −41 and +36, respectively, in units of 10^{-40} c.g.s., while the rotational strength of the amide absorption due to the random-coil conformation[8] is −14 in the same units. Since the energy interval (2,700 cm^{-1}) between the parallel and the perpendicular transitions is less than one-half of the band width of the resultant absorption, the respective circular dichroism bands overlap, and, having opposed signs, they mutually cancel to some degree, as is shown by the relatively large separation (5,800 cm^{-1}) between the two circular dichroism maxima observed. Owing to the cancellation in the wave-length region of overlap, the absolute magnitudes of the two rotational strengths due to excitation-coupling in the α-helix are larger than the values obtained experimentally from the solution circular dichroism measurements, which thus afford only a semi-quantitative support for the Moffitt theory.

From the agreement between his theory and the evidence available, Moffitt[1,4] suggested that polypeptides derived from the L-amino-acids should form a right-handed α-helix, and the prediction was afterwards verified by the X-ray diffraction study[9] of myoglobin.

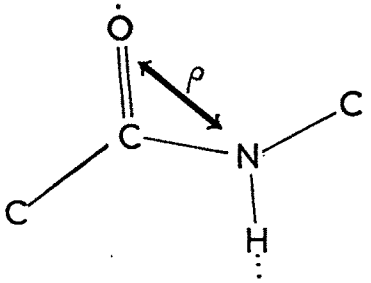

Fig. 3. The orientation in the amide group of the transition moment, ρ, giving the 1900 Å peptide absorption

Much of the evidence supporting Moffitt's theory was not available at the time of the amended treatment of Moffitt, Fitts and Kirkwood[5], and hitherto the subsequent experimental studies have given only a phenomenological status to the earlier theory. However, the physical model of the theory appears to be valid, for the additional terms contributing to the rotational strength of the polypeptide α-helix in the Moffitt, Fitts and Kirkwood treatment are important only in a helical segment consisting of a few amide groups.

The quasi-symmetric coupling of the $\pi \rightarrow \pi$ excitations of two amide chromophores composing a segment of the α-helix (Fig. 1*c*) makes two contributions to the rotational strength of the segment. Both contributions are negative in sign, and one is directed parallel, $R_{\parallel}^{s}$, and the other perpendicular, $R_{\perp}$, to the axis of the helix, namely:

$$R_{\parallel}^{s} = 2\pi\nu d\rho^2 \cos t \cos v \sin^2(\pi/P) \quad (4)$$

and:

$$R_{\perp}^{s} = -\pi\nu Z\rho^2 \cos^2 t \sin(2\pi/P)/2 \quad (5)$$

where Z is the rise per residue along the helix axis, and $2\pi/P$ is the angle about the helix axis between two adjacent amide residues (Fig. 2).

Similarly, the quasi-antisymmetric coupling of the two amide-group excitations makes two contributions to the rotational strength of the segment (Fig. 1*d*). Both the contributions have a positive sign, and both are directed perpendicular to the helix axis:

$$R_{\perp}^{a} = -2\pi\nu d\rho^2 \cos t \cos v \sin^2(\pi/P) \quad (6)$$

and:

$$R_{\perp}^{a'} = \pi\nu Z\rho^2 \cos^2 t \sin(2\pi/P)/2 \quad (7)$$

The original terms of Moffitt's theory[1] are those of equations (4) and (6), and the additional terms of the Moffitt, Fitts and Kirkwood treatment[5] are those of equations (5) and (7).

For an extended array of amide residues in the polypeptide α-helix there are, in general, two residues adjacent to any given amide group, disposed at angles to it of $\pm (2\pi/P)$ about the helix axis. The interaction of the excitation moment of the amide group with those of the adjacent residues contributes terms to the rotational strength of the α-helix according to equations (4) to (7). The contributions determined by equation (5) cancel one another, and so do those governed by equation (7), since the contributions depend in each case on $\sin(2\pi/P)$, which is negative for one of the adjacent residues and positive for the other. On the other hand, the contributions governed by equation (4) or (6) are additive, as they depend in each case on $\sin^2(\pi/P)$. Similar considerations apply to the coupling of the excitation moment of a given amide group with those of its two *n*th neighbours, and to interactions involving the terminal residues. The coupling of the excitation moment of the first residue in the α-helix with that of a given neighbour makes a contribution, governed by equation (5) or (7), which cancels the corresponding term derived from the analogous interaction involving the *N*th residue.

Physically the sum of the contributions to the rotational strength determined by equation (5) or (7) vanishes for n turns of the helix, such that nP is integral, or, more generally, when N becomes large, because the terms of either equation depend only on the tangential components of the amide excitation moments. The tangential components, $\rho \cos t$ (Fig. 2), interact in the quasi-symmetric coupling mode of the α-helix (Fig. 1*a*) to give only a magnetic moment, and in the quasi-antisymmetric coupling mode (Fig. 1*b*) to give only an electric moment, so that in neither case are the conditions (equation 1) for a non-zero rotational strength fulfilled.

It is concluded that the only significant contributions to the rotational strength of the α-helix are the terms of equations (4) and (6), which form the basis of Moffitt's original theory[1]. Equations (5) and (7), from the amended treatment[5] of Moffitt, Fitts and Kirkwood, contribute terms which sum to zero for a polypeptide α-helix with N large or with nP integral, and for a helix with nP non-integral they contribute only a small end-correction term with a value of the order of $1/N$ of the main terms governed by equations (4) and (6). Thus the 'Moffitt plots' of $[M']_\lambda(\lambda^2 - \lambda_0^2)$ against $(\lambda^2 - \lambda_0^2)^{-1}$ (equation 3) have a physical and not merely a phenomenological basis, and they may be relied on to give[4], from the sign and the magnitude of the constant, b_0, the proportion of a given polypeptide assuming the α-helix conformation in the particular conditions studied, and the chirality of the helix formed.

I thank Prof. P. Doty for permission to reproduce Fig. 4.

HIGH-SENSITIVITY DETECTION OF AMINO-ACIDS BY GAS CHROMATOGRAPHY AND ELECTRON AFFINITY SPECTROMETRY

By Dr. R. A. LANDOWNE and Prof. S. R. LIPSKY
Department of Internal Medicine, Yale University School of Medicine, New Haven, Conn.

SINCE the classical work of Sanger in 1945[1] on the determination of the structure of insulin the technique of end-group analysis of proteins via formation of 2,4-dinitrophenyl amino-acid derivatives (DNP's) has become a basic procedure in this field. The method, in its present-day refinements, offers a mean of selectively 'tagging' the free amino-groups of peptide chains which on hydrolysis yield coloured amino-acid derivatives with a relatively high absorption in the ultra-violet. This phenomenon is due strictly to the very active chromophoric 2,4-dinitrophenyl group attached to the amino nitrogen. These derivatives are now easily chromatographed by either appropriate paper or column techniques. Because of their colour, their position is readily discernible and identification is facilitated by comparing retention factors with those of pure standards. Following their elution and isolation they are determined quantitatively by ultra-violet spectrophotometry.

An extension of this technique would be the complete hydrolysis of the peptide prior to reaction with 1,2,4-fluorodinitrobenzene, the DNP forming reagent, thereby yielding the DNP derivatives of all the amino-acids present in the hydrolysate[2]. This technique is similar to the at present more popular method of Moore and Stein for automatic amino-acid analysis[3,4], whereby the ninhydrin derivatives of amino-acids are simultaneously

chromatographed and quantitatively determined by virtue of their high absorption in the visible region.

Certain disadvantages of these techniques are inherent, particularly the length of time necessary for a complete analysis (18–24 h for the Moore–Stein method or 20 h for the recently automated DNP technique[5]) and the sensitivity of the method or minimum amount of each amino-acid component required for detection. For the Moore–Stein technique about 10^{-7} moles of sample are needed[3], while approximately 10^{-8} moles of DNP derivatives are required to yield a proper colorimetric analysis of these compounds[6].

In the past few years great strides have been taken in order to adapt amino-acid analysis to the rapidly developing realm of gas chromatography[7–9]. Preparation of a number of derivatives of amino-acids, usually the combination of *N*-acyl esters, has enhanced their volatility and promoted their elution from gas-liquid columns in about 60 min. The concurrent use of the highly sensitive ionization detectors has increased the level of detectability for amino-acids to about 10^{-12} mole/sec, which in practical terms signifies that approximately 10^{-10} moles of the protein or peptide would be required as starting material[8].

Because of the high molecular weight of most biologically important proteins and the difficulty of isolating them in pure form in large amounts it seemed desirable to improve further the sensitivity of detection of amino-acids to lessen the burden of procuring workable quantities for analysis. From past experience[11,12] it was reasoned that the use of the electron capture detector[10] in conjunction with gas chromatography could readily satisfy the need for higher sensitivity. The only major problem that remained was to find a volatile amino-acid derivative that possessed an electrophoric group with a high affinity for free electrons. Although most amino-acids do not contain such groupings, certain derivatives can be prepared to satisfy this requirement. This concept is not new to protein chemists who have used and continue to use chromophoric derivatives for colorimetric or ultraviolet analysis as cited here. However, it is relatively unique to gas chromatographic analysis, having only recently been applied to the analysis of sterols as their chloroacetates[11]. Indeed, from a theoretical point of view *N*-chloroacetyl amino-acids also could be used for the same purpose. This will be the subject of another communication.

From earlier work with this detection system, although not unanticipated, it was noted that many well-known chromophoric groups are also highly electrophoric when measured by this device. An excellent example of this phenomenon proved to be the 2,4-dinitrophenyl group, which was originally measured as 2,4-dinitrophenol[10]. Since a great deal is known about the formation of DNP amino-acids and their behaviour under various conditions of hydrolysis a logical extension and improvement of the present methods of amino-acid analysis using these compounds was the application of gas chromatography in conjunction with electron affinity spectrometry.

The compounds tested were obtained commercially as the 'chromatographically pure' free DNP acids (Mann Research Laboratories, New York) and converted to the methyl esters by reaction with ethereal diazomethane. Where poor solubility was encountered, as noted by slow evolution of nitrogen, methanol was added to speed the reaction. The compounds were diluted in methanol to a known concentration after being taken to dryness under nitrogen to remove excess diazomethane and ether. They were then applied to the gas chromatographic column by injection with a 1-μl. syringe.

The DNP amino-acid methyl esters were chromatographed at a temperature of 220° C. Injection temperature was 275°–285° C. The most useful stationary phases for this preliminary study were the neopentyl adipate or neopentyl sebacate polyesters[9,13] or the polar nitrile containing silicone, '*XE*60'. 3 per cent of the phase was coated on 90–100 mesh 'Anakron *ABS*' (Analabs, Hamden, Conn.). Once it was demonstrated that the DNP tagged amino-acid esters could be eluted under reasonable conditions their response toward detection by the electron capture device was determined. The standard 1-cm parallel plate detector previously described and studied was used[12]. Sensitivities were determined at an optimum potential of 14 V applied to the detector, which was maintained at 200° C. The rate of flow was 200 ml. argon/min. Sensitivity here is defined as the minimum detectable amount based on a peak height of twice the overall noise-level, which essentially is a composite of stationary phase emerging from the column and electronic noise. The latter was substantially reduced by placing a 0·001-μF capacitor across the input of the electrometer–amplifier commonly used with this equipment. This reduced the noise-level to 6×10^{-13} amp.

When the response exceeded 30 per cent of the saturation current, the sample was further diluted to reduce the signal and to place it within the linear range of the detector. This permitted valid calculation of the sensitivites which are reported in Table 1. The linear range for this system is about 2,000–4,000 times these minimum detectable amounts.

Table 1. Sensitivity of DNP Amino-acid Methyl Esters

Amino-acid	Minimum detectable amount ($\times 10^{-16}$ mole/sec)
Alanine	3·60
β-Alanine	2·65
α-Amino butyric acid	3·24
γ-Amino butyric acid	2·92
Aspartic acid	3·22
Cystine (di-DNP)	3·30
Glutamic acid	2·78
Glycine	3·07
Isoleucine	3·36
Isovaline	3·12
Leucine	2·94
Lysine (di-DNP)	2·45
Methionine	3·41
Norvaline	3·96
Ornithine (di-DNP)	3·60
Phenylalanine	2·13
Proline	3·27
Valine	3·21
Average (± *S.D.*)	3·12 ± 0·41 (13%)

Significantly, the minimum detectable quantities of the various DNP amino-acids were of the same order of magnitude, namely, 3×10^{-16} moles/sec, with a relative standard deviation of ± 13 per cent. This is well within the experimental error expected in measurements of this type, and clearly indicates that the sensitivity is strictly governed by the affinity of the 2,4-dinitrophenyl group for free electrons. The remainder of the molecule apparently does not exert any influence in this regard. This is a very valuable asset when using a specific type of sensitive ionization detector, since previous experience with both the conventional 'flame' and 'argon' ionization devices has shown that responses vary significantly with changes in molecular structure. However, in this instance, the electron capture device responds only to the highly electrophoric dinitrophenyl group, thus providing a predictable quantitative result. This precludes any need for calibration once reproducible optimum operating parameters are ascertained for the chromatographic column-detection system[11].

It was noted that for the lysine, ornithine and cystine di-DNP methyl esters the sensitivities were still the same as that observed for the mono-DNP derivatives. At first it was thought that these substances would evoke a two-fold increase in response since two DNP groups were present in the molecule. This was not the case, however, since structurally the two groups are far apart and incapable of any interaction that would promote electron attachment over and above that expected for either group alone. It is apparent that as soon as one of the groups has captured an electron a negative molecule-ion is formed and the possibility of such a species capturing a second electron is almost nil in the prevailing circumstances. Thus the fact that those amino-acids containing

more than one reactive amino-group respond similarly to the mono amino-acids is a further advantage of this technique.

Finally, a problem often encountered in microanalyses is the appearance and interference of impurities. Many unknown substances of an organic nature often arise from many sources and are difficult to eliminate. Often, these are impurities that are carried along in the initial extract and cannot be removed by even the best purification techniques. In addition, after certain isolation procedures there are those that appear from either the solvents or the column materials used. Fortunately the unique sensitivity of the electron capture detector to the DNP derivatives makes ultimate purification unnecessary. This is possible because when operated at optimal conditions the detector will selectively respond only to those compounds capable of forming a DNP derivative or to those rare compounds with comparable electron affinities. Thus a multitude of other substances need not be eliminated by oft-times tedious preliminary purification procedures, since the unusual properties of the electron capture detector will accomplish this end by itself. Such an approach has already been used most effectively in other areas of gas chromatographic analysis using this type of sensing system, for example, insecticides, lead compounds.

In conclusion, it is evident that the advantages of electron capture spectrometry in conjunction with the gas chromatography of DNP amino-acids are three-fold. These are: (*a*) the extreme sensitivity not heretofore reported for any other biologically significant group of compounds; (*b*) the uniformity of response toward all the DNP amino-acids; (*c*) the inherent selectivity of the detector that eliminates interference from impurities that would otherwise be troublesome at the exceedingly low levels of detection that can now be used.

Although the dinitrophenyl group is quite polar and adds significantly to the molecular weight of many amino-acids which already are difficult to volatize it was nevertheless found quite feasible to analyse them by gas chromatography at a reasonable temperature. The use of the butyl or amyl esters[8] of the DNP amino-acids would further increase their volatility compared with their methyl esters, thus enhancing the rapid elution of some of the higher molecular weight compounds. Before this can be done, however, it is necessary to determine the ease of esterification and its quantitative aspects. At present, the use of diazomethane, with its known rapid, quantitative formation of methyl esters seems quite sufficient for the amino-acids already tested. With the extremely small samples that can now be applied to the gas chromatographic column, the possibility of adsorption of the sample on the column can become a serious problem. It is therefore essential that adsorption effects are minimized in order to obtain the highest sensitivity. This can be achieved for the most part by the use of glass columns, pre-treated solid supports (acid and base washed and siliconized), the proper liquid phase (polar) and amount thereof, and the careful elimination of dead volume from the entire system. It is conceivable that under ideal operating conditions the limits of detection and linear range may be extended by one or more orders of magnitude than that reported here at this time.

Work is now proceeding to determine the most convenient conditions under which all the important DNP amino-acid esters can be resolved by gas chromatography. If this is readily accomplished the method will undoubtedly become the one of choice for the ultramicroanalysis of amino-acids.

PLUTONIUM-239 AND OTHER NUCLIDES IN GROUND-LEVEL AIR AND HUMAN LUNGS DURING SPRING 1962

By Dr. R. V. OSBORNE*

Department of Physics, Institute of Cancer Research, Royal Cancer Hospital, London, S.W.3

IN nuclear weapon explosions, some of the fissile nuclides may not undergo fission, so that these nuclides, together with neutron capture products, may be dispersed from explosions in the atmosphere. Many of these nuclides are α-emitters[1], but the comparatively high levels of natural α-activity complicate their identification and measurement. In particular, the α-energies of plutonium-239 (5·15 MeV) and plutonium-240 (5·16 MeV) are very close to that of polonium-210 (5·30 MeV), the naturally occurring α-emitter which follows the β-emitters lead-210 (radium D; half-life, 20 years) and bismuth-210 (radium E; half-life, 5 days) in the decay of the radon-222 series. The residence time in the atmosphere of the Rn-222 series is sufficiently long for an appreciable activity of polonium-210 (half-life, 138 days) to be formed in the atmosphere[2]. A technique, described in this article, has been developed so that plutonium-239 and/or plutonium-240 may be measured directly in ground-level air at concentrations as low as 5×10^{-17} c./kg despite the presence of polonium-210. Since, in these measurements, an attempt has been made to distinguish plutonium-239 and plutonium-240 they are referred to, for convenience, so plutonium-239. The method uses an α-spectrometer with an energy resolution and sensitivity capable of distinguishing plutonium-239 and polonium-210 at the low activities associated with such samples. The results of preliminary measurements with this technique, together with other measurements of zirconium-95 + niobium-95 and plutonium-239 in human lungs, are reported and discussed here.

Alpha-particle spectrometry. A parallel plate, Frisch-grid, ionization chamber, accommodating four interchangeable sources each of up to 200 cm², was used in the measurements described in this article. Less than 0·005 pc. of plutonium-239 or polonium-210 doubled the effective background counting rate for these nuclides and α-spectra with 40–50 keV half-widths (full width at half the height of a spectral peak) could be obtained from a thin source at 2π geometry. The head amplifier used was based on the design published by Cottini *et al.*[3].

* Present Address: Biology and Health Physics Division, Atomic Energy of Canada, Ltd., Chalk River, Ontario.

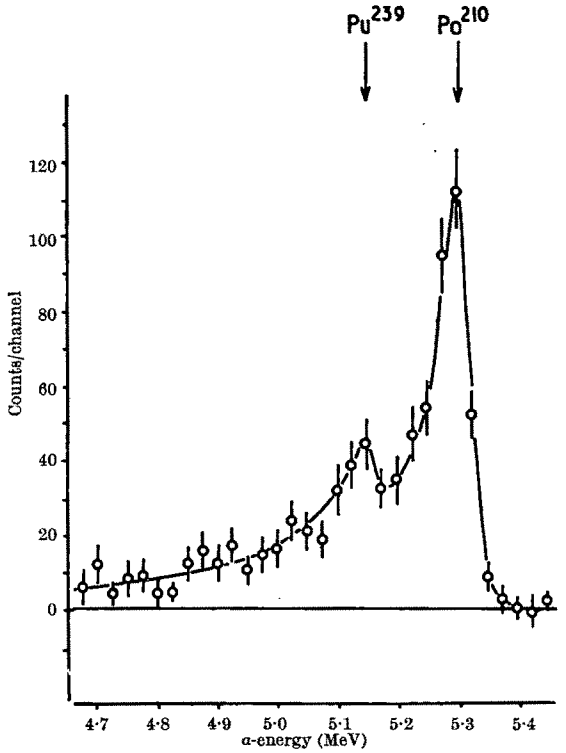

Fig. 1. α-spectrum from atmospheric dust collected during January 30–February 1 and counted 55 h

Subsequent measurements are being made with a spectrometer which has recently been designed and constructed in the form of a gridded cylindrical ionization chamber. This instrument, the details of which will be given elsewhere, has a source area of 1,800 cm² and half-widths of the order of 30 keV can be obtained.

Collection and analysis of atmospheric dust samples. As part of the programme of air monitoring by this Department[4], samples of dust from ground-level air at Sutton, Surrey, are collected on the plates of an electrostatic precipitator (efficiency 98 per cent as measured for methylene blue particles). For β- and γ-counting, the dust is removed from the plates by washing[4]; but sources in a form suitable for α-particle spectroscopy can be prepared by collecting the dust directly on aluminized melinex ('Mylar') sheets stretched over one of the precipitator plates. In this manner, 200 cm² sources having 20–30 μg dust per cm² are obtained in 40–50 h from 300–500 kg of air.

The sampled air mass was estimated for each sample by comparison of the γ-activity of the fission products zirconium-95 + niobium-95 collected on the melinex sheet with that collected by the total precipitator, for which the rate of flow was known. These γ-activities were measured with a 3-in. sodium iodide crystal in a low-background counting facility described previously[4].

Another method of estimating the sampled air mass was to measure the total α-activity of an aliquot from the total dust sample using a zinc sulphide scintillation technique[5] and compare this with the total α-activity on the spectrometer source as calculated from the α-spectrum. The overall agreement between the two methods was within 10 per cent.

The collection of the short-lived daughters of the naturally occurring radon-222 and radon-220 necessitated a delay of several days after the sample was collected, before commencement of the α-analysis in the spectrometer described above. By following the long-term build-up of total α-activity in the dust samples collected by the precipitator, the concentration of lead-210 in air and the ratio of polonium-210 activity to lead-210 activity at time of sampling were also estimated.

Analysis of lung samples. Complete pairs of lungs, together with the associated lymph nodes, were obtained from human adults from southern England who had died suddenly and had not had a long period in hospital immediately prior to death. The samples were ashed at 450° C in a muffle furnace and the zirconium-95 + niobium-95 γ-activity of the ash was measured using the 3-in. sodium iodide crystal in the low-background counting

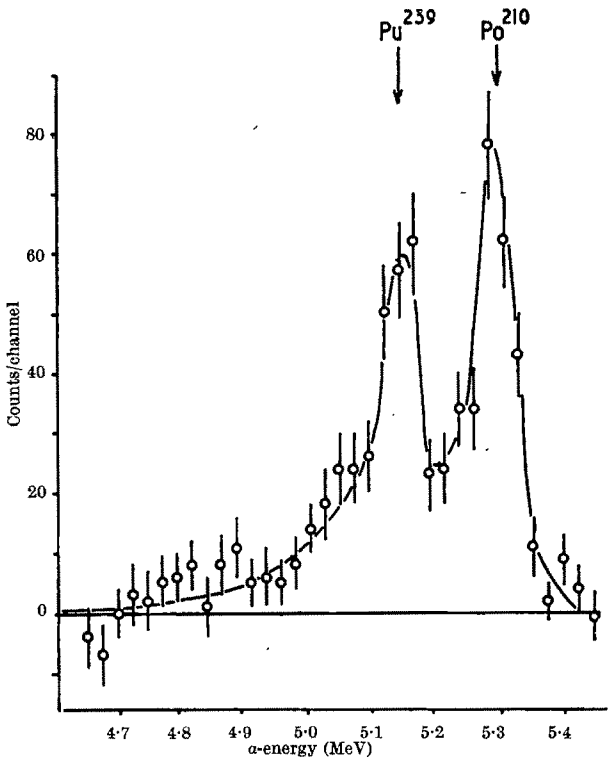

Fig. 2. α-spectrum from atmospheric dust collected during May 7–9 and counted 55 h

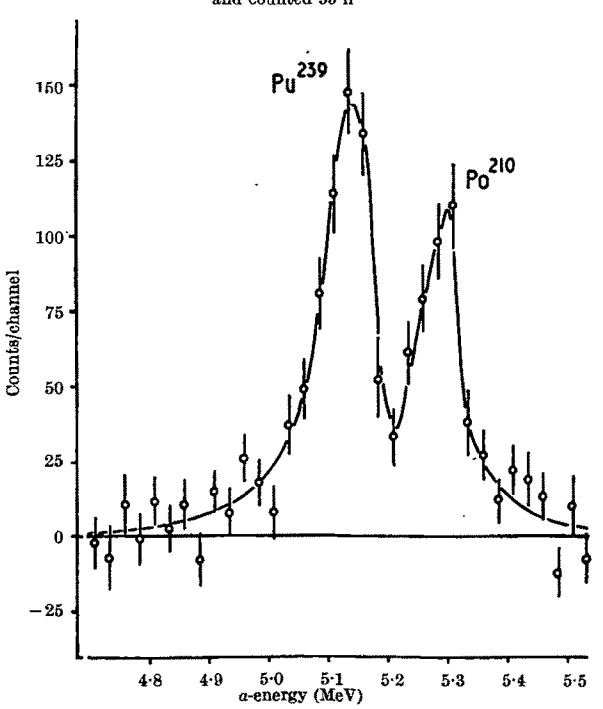

Fig. 3. α-spectrum from atmospheric dust collected during June 18–20 and counted 116 h

facility mentioned here. Because of the very low specific activity of plutonium-239 in lungs it was necessary to separate the plutonium chemically prior to assay. The separation, which will be described in detail elsewhere, was based on the selective absorption of plutonium (IV) from 7·5 N nitric acid by a column of strong base anion exchange resin. The plutonium was then eluted and further purified by solvent extraction with 2-thenoyltrifluoroacetone (T.T.A.) in benzene. Finally, the plutonium was electroplated on a stainless steel disk and the activity measured in the α-spectrometer. This allowed assay of the plutonium-239 without interference from any polonium-210, which is known to be present in soft tissues in appreciable concentrations[7] and which may have come through the chemical separation. Assay by α-spectroscopy also enabled accurate determination of the overall recovery of plutonium to be made: the sample was spiked with plutonium-238 (α-energy, 5·50 MeV) prior to the separation and the activity of plutonium-238 in the α-spectrum was measured. (The results of the air measurements reported here and also those by other workers[6] indicate that the activity of any plutonium-238 present in the atmosphere is much less than that of plutonium-239.)

Results. Spectra obtained from atmospheric dust, sampled in the manner described here, are shown in Figs. 1–3. Generally the activities analysed were less than 10^{-13} curies so that, although the counting times were 50–120 h, the standard deviations from counting statistics (shown in the spectra) were quite large. From the α-energies of the observed peaks, the long-lived activity was attributed to plutonium-239 and polonium-210. The plutonium-239 concentrations in the air, measured at approximately weekly intervals, are shown in Fig. 4, and the estimated lead-210 concentrations and polonium-210/lead-210 ratios are summarized in Table 1.

The results of the measurement of plutonium-239 and zirconium-95 + niobium-95 in lungs are shown in Table 2.

Plutonium-239 in the atmosphere. The levels show a rather drawn-out spring peak similar to that observed[9] for fission products. The average of the plutonium-239 concentrations measured during the period February to July 1962 was 20×10^{-17} c./kg air and this corresponds to approximately 0·08 per cent of the maximum permissible level of continuous exposure for large populations[8]. The mean ratio of cæsium-137 activity (estimated[9] from the measured zirconium-95 + niobium-95 concentration and the age of debris) to plutonium-239 activity for the samples measured during this period was 122 ± 8, which is not very different from previously reported ratios[10,11].

Polonium-210 and lead-210 in the atmosphere. The average lead-210 concentration in air observed during the period of these measurements was $3{\cdot}2 \times 10^{-15}$ c./kg, which is very close to that reported previously by Burton *et al.*[2]. However, except for the last month (June), the polonium-210/lead-210 ratio was higher than the value (0·1) reported by the same workers. The highest value observed here occurs near the commencement of the spring peak in plutonium-239 fall-out (Table 1, Fig. 4).

Table 1. Lead-210 Activity and the Ratio Polonium-210/Lead-210 in Ground-level Air, February to June 1962

Month (1962)	No. of samples	^{210}Pb 10^{-15}c./kg air	^{210}Po/^{210}Pb
February	2	3·3	0·24
March	3	2·0	0·48
April	5	3·3	0·21
May	7	3·2	0·15
June	5	3·9	0·09

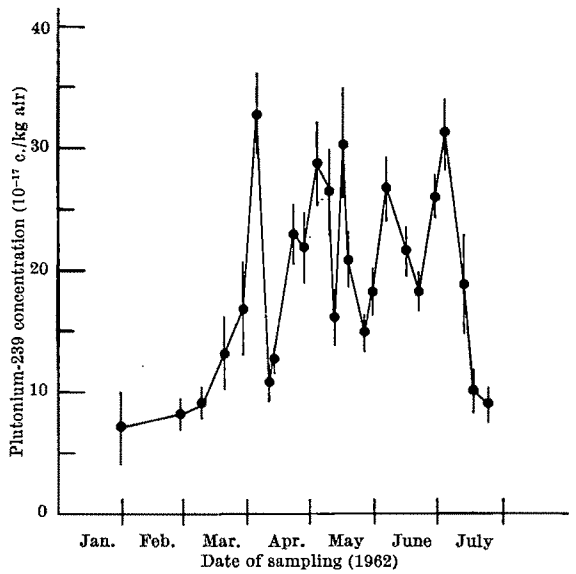

Fig. 4. Concentration of plutonium-239 in ground-level air, measured at weekly intervals during 1962. Vertical lines are standard deviations from counting statistics only

Burton *et al.* (*loc. cit.*) have suggested that some of the lead-210 measured at ground-level may have circulated through the stratosphere with a mean residence time of several months in a manner similar to debris from nuclear weapon tests in the atmosphere. The other component of the lead-210 at ground-level has been formed and has remained in the troposphere with a mean residence time of only a few weeks. The high polonium-210/lead-210 ratios observed here may, therefore, be a result of a higher contribution from the older stratospheric component relative to the tropospheric lead-210. The possibility exists, however, that some of the polonium-210 observed early in the spring may have been artificially produced from bismuth (bismuth-209) in weapon detonations.

Plutonium-239 and zirconium-95 + niobium-95 in human lungs. The burdens of zirconium-95 + niobium-95 at the time of death were comparable with those reported by Rundo *et al.*[12]; but the plutonium-239 levels were, in general, lower than those reported for specimens taken during 1954–59 [7,13]. The average lung burden of plutonium-239 found here (0·16 pc.) was approximately 6 per cent of the average polonium-210 activity measured in other individuals[14]. The average total α-activity of adult lungs in Great Britain has been given[15] as 8 pc.

The radiation doses to the lungs from the measured activities of zirconium-95 + niobium-95 and plutonium-239 are 2·4 mrem/y and 0·17 mrem/y respectively. For comparison, the lung dose from polonium-210 is estimated[14] to be 3 mrem/y. However, the actual distribution of the various nuclides, particularly the α-emitters, will have considerable effect on the irradiation pattern and any assessment of the significance of these activities from a biological point of view must take this into consideration.

Relation of lung burden and atmospheric concentration. The measurement of both the atmospheric concentration and the lung burden of a given nuclide provides opportunity to evaluate the validity of some of the 'standard man' parameters associated with lung retention. Here, although only a few measurements have been made, some estimations may be carried out regarding the lung retention of zirconium-95 + niobium-95 and plutonium-239.

Assuming that the International Commission on Radiological Protection (I.C.R.P.) single exponential model[8], characterized by a half-life T days, is valid for lung retention and excretion, the lung burden N pc. after inhalation of I pc./day for t days is given by:

$$N = \frac{fIT}{0{\cdot}693}\left[1 - \exp\left(\frac{-0{\cdot}693t}{T}\right)\right]$$

where f is the fraction of inhaled material which is not exhaled or quickly swept out of the respiratory tract and swallowed. Both f and T may vary considerably with the character of the aerosol.

Considering the zirconium-95 + niobium-95 results and taking an average burden per person as 245 pc., the fraction f may be estimated using the foregoing expression as follows. The average zirconium-95 + niobium-95 activity in the air at Sutton, Surrey, during the period January–May 1962 was approximately 1 pc./kg air[9]. If the biological half-life (T_b) is much greater than the physical half-life (T_r) of a nuclide in the lungs, the effective half-life (T) is only slightly less than T_r. In the case of zirconium-95 + niobium-95 (T_r = 65 days), if T_b is not less than the 120 days suggested by the I.C.R.P.[8] for insoluble particles, the effective half-life will be between 40 and 65 days. Supposing that the daily inhalation is the standard 26 kg air, the value of f, calculated with these parameters in the above equation, lies in the range 14–19 per cent. The I.C.R.P. suggests 12·5 per cent for f.

Assuming that the particle size distribution of plutonium-239 was similar to that of the zirconium-95 + niobium-95, so that the same value of f was effective, the lung burden of plutonium-239, at the end of June 1962, may then be predicted from the above equation. With f = 14–19 per cent, T = 120 days and taking the average activity of plutonium-239 in the air as 20×10^{-17} c./kg air for the three months prior to this time and 7×10^{-17} c./kg for the period 1955 until March 1962 from the foregoing results and others[16], the predicted burden is 0·10–0·13 pc., which is of the same order as that measured. Thus, the foregoing results and the 'standard man' parameters appear to be reasonably consistent.

Possible levels of plutonium-239 in other tissues. From ref. 16 and the results given here, the total plutonium-239 inhaled up to June 1962 by a 'standard man' in England can be calculated to have been of the order of 5 pc. Of the 14–19 per cent suggested here as being retained in the lung with an effective half-life of 120 days or longer, approximately 0·16 pc. was still there in June 1962. Absorption of plutonium via the gastrointestinal tract is extremely small[8], so, assuming only 19 per cent of the inhaled material was available for intake to the body fluids, not more than 0·8 pc. would have been absorbed and transferred to other tissues from the lungs. If it is assumed that this activity of plutonium-239 is redistributed in the proportions suggested by the I.C.R.P., then the activities in bone, liver and kidney would be less than 0·6 pc., 0·12 pc. and 0·016 pc. respectively. (The natural α-activity of these tissues has been given[7] as 400 pc., 9 pc. and 1 pc. respectively.) The only reported value which can be compared with the foregoing is a measurement of plutonium-239 in human kidney[13]. This gave ten times the activity suggested here as an upper limit.

I thank Prof. W. V. Mayneord for his advice and encouragement. I also thank all those members of the Department who have assisted in some way or other, in particular, Mr. J. O. Crookall, who designed and carried out the chemical separation procedure, Dr. C. R. Hill and Dr. R. P. Parker. I also thank Dr. W. O'Bank (of the Department of Forensic Medicine) and Dr. P. J. Roylance for providing the post-mortem material. This work was performed under tenure of a Department of Scientific and Industrial Research research studentship.

RETINAL PHOTOCOAGULATION BY LASERS

By N. S. KAPANY and N. A. PEPPERS

WHEREAS coagulation of detached retinæ with light has been performed for many years, the present-day techniques suffer from long exposure time, large size of the lesions, and awkward and expensive apparatus. With the advent of lasers the use of a high-energy light source which can deliver the required amount of energy over a short time and cause lesions of small size has become possible. Furthermore, the overall instrumentation can be compacted to the size of conventional ophthalmoscopes.

Photocoagulation is used largely for the treatment of retinal detachment. This common eye disorder occurs in thousands of people each year and, if allowed to develop fully, ultimately results in blindness. The technique offers advantages over previous methods of retinal coagulation. For example, retinal coagulation by diathermy needle takes several hours and general anæsthesia is required. Furthermore, this is often a 'blind' procedure in the sense that the portion of the retina which is to be coagulated is not viewed directly during the use of the needle. Also, the recuperation period is prolonged. In contrast to this method, photocoagulation is a very simple procedure which can be accomplished in a few minutes. Moreover, a general anæsthetic is never required, the spot which is to be coagulated is always directly in view, the affected area is relatively small and well defined, and the recuperation period is not painful and rarely exceeds a few days.

Investigations of damage by light to the retina[1] were carried out as early as 1867 when an attempt was made to burn the retina of rabbits with sunlight. However, it was not until 1945, when intense artificial light sources

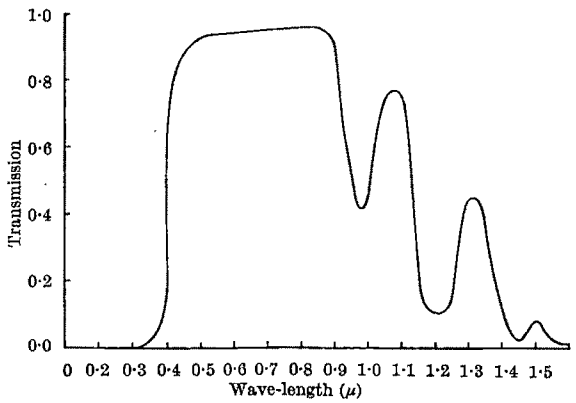

Fig. 1. Spectral transmission curve of the refractive media of the human eye

were available, that therapeutic light coagulation appeared promising. By 1949 Meyer-Schwickerath[2] and Littman had developed a technique and an instrument for practical therapeutic light coagulation. In this instrument, light from a continuously operated high-pressure xenon lamp is transmitted along a train of optical components located in a long, movable arm which extends from the instrument. At the end of the drum is a mirror with a small hole through which viewing and aiming are done. The lens of the patient's eye causes the light to be focused on the retina where a lesion is produced. The light intensity can be adjusted to obtain the desired effect in an exposure of about 0·25–1·5 sec.

Coagulation Using Lasers

A new class of unique light source, namely, optical masers and lasers[3–5], is now available for photocoagulation work. These sources are monochromatic and emit light at various wave-lengths both in the visible and infra-red. A common solid-state laser configuration consists of an active material (polished flat and parallel at the ends) which is placed on the axis of a helical xenon flash lamp. For a period of time (typically $\simeq$ 300 μsec) an intense flash from the xenon lamp causes more active material ions to exist in an upper quantum state than are in the ground state. During this period, light which travels parallel to the cylinder axis is amplified and an intense, highly collimated, monochromatic, coherent light beam is emitted.

(*a*) *Selection of Wave-length.* In selecting a wave-length for retinal photocoagulation one must consider the optical properties of the eye as well as the difficulties of obtaining required amounts of light at a given wave-length. Fig. 1 shows the transmission of the refractive medium of the human eye[2]. It appears that for photocoagulation work the wave-length of light should be confined to the portion of the spectrum between 0·4 and 0·9μ or possibly to the infra-red region around 1·08μ. At these wave-lengths the light will pass through the vitreous and aqueous humours and the retina, and will be absorbed in the pigment epithelium and the choroid. At the present time there are only two laser materials which conveniently give practical amounts of energy in these regions. These materials are chromium in alumina (ruby), which emits at 6943 Å, and the neodymium in glass, which emits at 1·06μ.

The fraction of the incident light which is absorbed in the fundus varies several hundred per cent[6] from one eye to another and also varies at different regions in the retina. However, the absorption does not vary rapidly with wave-length in the visible and slowly falls towards the infra-red. Because of this and because the transmission of the refractive media of the eye is higher in the visible than in the infra-red, ruby appears to be favoured over neodymium. However, there is a possibility that instrumental considerations associated with neodymium may make its selection advantageous.

(*b*) *Photocoagulation Process.* All the biophysical details of the absorption-coagulation process are not fully understood. Certainly the effect is dependent on power although the extent is not known. Soesterberg[7] has advanced a theory which appears to be applicable to light sources less powerful than lasers. A mathematical description of the process is reported by Rose *et al.*[6] Qualitatively, the process is quite simple. During the time ($\simeq$ 300 μsec) when light energy is delivered to the fundus, very little energy can escape to the surrounding tissue either by convection within the capillary system or by conduction to surrounding tissue. Because of this, the temperature of the small amount of tissue which absorbs the energy becomes highly elevated. If a large amount of energy is delivered rapidly, tissue fluid is vaporized and the vapour erupts through the retina into the vitreous humour and a bubble is formed. A hæmorrhage or a retinal hole can also be caused under these conditions. If more moderate amounts of energy are delivered, the absorbing tissue is not vapourized and some of the stored energy is passed on to the retina causing it to be coagulated and 'welded' to the choroid.

Experimental Laser Photocoagulator

An experimental laser photocoagulator has been built to determine laser parameters pertinent to photocoagulation and also to provide an instrument for clinical testing on rabbits, cats and human beings. Fig. 2 illustrates, diagrammatically, the optical features of this instrument. Here a collimated beam of light is emitted from the active laser material and is focused by the lens of the eye on to the retina where a lesion occurs. Provision is made so that the active medium can either be a cylindrical ruby crystal or a cylinder of neodymium-doped glass. The instrument is about the size and weight of a normal ophthalmoscope so that it can be controlled easily with one hand. Direct ophthalmoscopic viewing is provided with an auxiliary light source and several examining lenses, both negative and positive. The laser configuration consists of a 0·25 in. × 3 in. rod placed between two linear xenon flash lamps surrounded by a specular reflector. For safety and reliability, the lamps are connected to independent storage capacitors although they are triggered from the same source. The capacitors are capable of delivering up to 800 joules of energy to the pumping source, that is, xenon lamps.

The energy output of the laser can be altered by varying the voltage to which the capacitor banks are charged. The result is that energy output and average power output are not independent variables, but rather they are related in some complex manner. Moreover, the instantaneous power output is a rapidly varying function of time and no attempt is made to control it[8]. In this instrument the total energy output of the laser was varied continuously from zero to 0·25 joule.

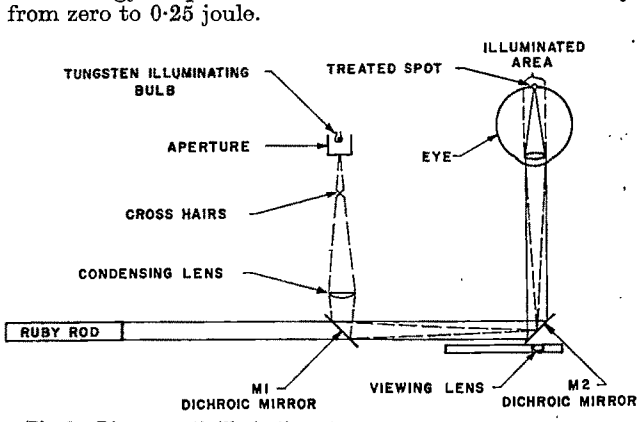

Fig. 2. Diagrammatic illustration of the optical features of the experimental laser coagulator

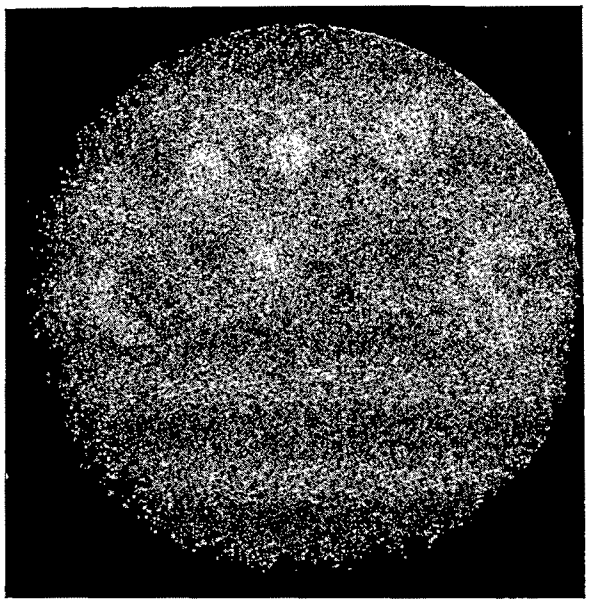

Fig. 3. Two rows of lesions showing effects of increasing laser energy on the size of lesions

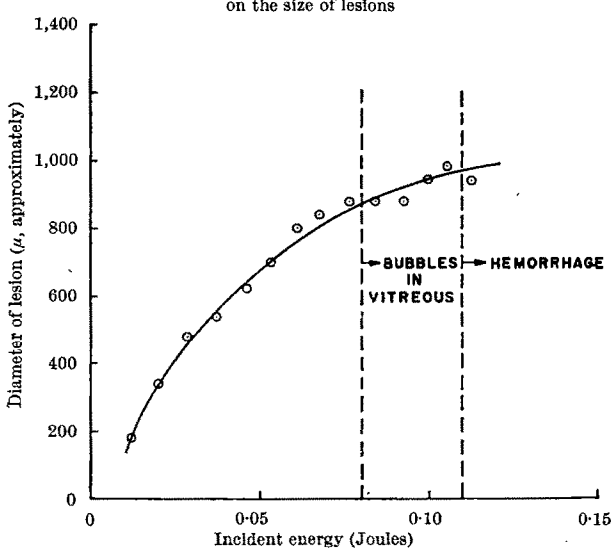

Fig. 4. Plot of the diameter of lesions versus incident laser energy. The bubbling and hæmorrhage thresholds are indicated

Experimental Results

So far all experimental work has been performed on rabbits or cats. In the experiments the animal is anæsthetized with intravenous pentobarbital and the pupils dilated with 10 per cent phenylephrine. After treatment with a laser photocoagulator and/or a Zeiss photocoagulator, photographs of the lesions are taken. Histological sections of the lesions are also made.

Immediately after laser coagulation the structure of the lesions is more apparent than in those caused by the Zeiss photocoagulator and are smaller in size. In the centre of the lesion is a dark crater, indicating a high local density, and concentric with this is a dark ring with smaller and larger white rings on either side. During the next few days the lesion changes in appearance and begins to look more like a uniform disk of affected tissue. This disk of affected tissue apparently is firmly attached to the choroid.

It was found that the coagulation threshold (minimum energy required for coagulation) varied grossly with colour of the fundus. This was expected and is related to the reflectivity and absorptivity of the fundus at 6943 Å, the wave-length of the radiation from the laser. In general, the threshold energy for a lightly pigmented fundus is higher than a darkly pigmented fundus. Variations of more than a factor of five were observed. The amount of damage caused by a given incident energy is also a function of the colour of the fundus. It is possible for a given incident energy to cause a hæmorrhage in a darkly pigmented fundus and yet not visibly damage an albino fundus. The energy-range over which good lesions can be caused without excessive damage varies markedly with the colour of the fundus. For example, for a particular Siamese cat with a pale fundus the ratio of energy required for a hæmorrhage to coagulation threshold energy was about eleven to one. This same ratio for a cat with a darker fundus was three to one. Similar variations were found with rabbits.

Investigations were carried out to determine the area of affected tissue as a function of incident energy. In general, the diameter of the lesion increases with increasing incident energy but not indefinitely. Fig. 3 is a photomicrograph showing this effect on the retina of a rabbit, on which two rows of lesions were caused. It will be noted that the energy associated with the lesions increases from left to right in both rows, with the lesion in the upper left being caused by the least amount of energy. In experiments on pigmented rabbit's retina, as the energy is increased bubbles begin to form between 0·08 and 0·11 joule, and finally hæmorrhaging occurs above 0·11 joule. Fig. 4 gives a plot of the diameter of lesions on a rabbit retina caused by varying the laser power output. The size of the lesions varies from 200μ to 1 mm when the energy is varied from 0·01 to 0·15 joule.

Histological sections of many of the lesions were prepared to determine the general character of the lesions, as well as the depth of penetration. In the process it was found that the retina usually separates from the choroid except at the sites where lesions were caused. This is evidence that the retina is indeed 'welded down' in these regions. Fig. 5*a* is a section of a typical lesion caused

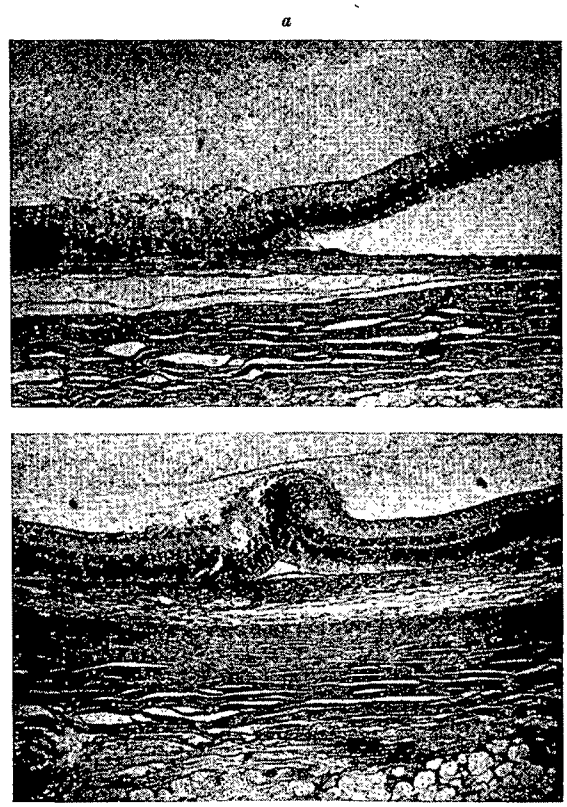

Fig. 5. *a*, Histological section of a normal lesion caused by laser photocoagulation; *b*, histological section of a lesion showing eruption through the retina due to high laser energy

in the retina of a rabbit. Scar tissue has formed above the retina and a general disruption of cells is apparent below this tissue. The retina has separated from the choroid except at the lesion. Fig. 5*b* is a section of a lesion through which a bubble erupted. It is obvious from the photomicrograph that the tissue which was vapourized was in the vicinity of the pigment epithelium and in fact probably was a portion of the pigment epithelium. The photomicrograph also shows that the retina has separated from the choroid except at the lesion. Other sections indicate that the pigment epithelium is affected at very low incident energies. Even at very high energies (0·25 joule) the damage does not appear to penetrate very deeply into the choroid.

Conclusions

Because of the large variations in colour of the fundus it will be necessary to begin any treatment at low energies and gradually increase the energy until the proper effect is caused. This change in energy-level can be caused both by varying the condenser voltage and by using calibrated filters in the beam. This procedure, however, is not objectionable and is generally followed today with the existing coagulator. There are a number of advantages offered by laser photocoagulation. The fact that the lesion which is caused is small is important when the macula of the eye is involved. The size of the lesion can be varied by varying the laser energy or by using an appropriate optical system. Also, since the lesion is caused in such a short time, the normal reaction of the eye to a bright light does not occur until after the process is over and thus the burn is not smeared across the retina. The ease of manœuvering and aiming a hand-held instrument with an ophthalmic viewing head, the fact that the patient does not need to be anæsthetized, and the potential low cost of the instrument are all important practical considerations which make retinal photocoagulation by lasers appear quite promising.

We thank N. Silbertrust for his assistance.

PARTITION OF DIVALENT CATIONS BETWEEN BACTERIAL WALL AND CELL CONTENTS

By Prof. J. M. VINCENT and Mrs. BEVERLEY A. HUMPHREY
Microbiology Laboratory, School of Agriculture, University of Sydney

A DETAILED examination of the requirements of *Rhizobium trifolii* for magnesium and calcium[1] correlates well with the results we have since obtained on the disposition of these elements in the cell wall and within the cell itself, under contrasting conditions of calcium deprivation and sufficiency[2]. The information so derived supports the indications we already have that calcium has a structural role in the wall of this organism. This role can be distinguished from the less specific part it shares with magnesium in meeting a much larger requirement by the cell for divalent cations.

Portion of the analytical data[2] can be shown graphically (Fig. 1) in such a way as to indicate the concentration of both elements in walls and cells (height of histograms) and their total distribution between the two (area). For this purpose and subsequent calculations we have taken 20 per cent as a fair estimate of the proportion of total cell mass likely to be represented by wall[3].

Three things call for comment: (*a*) Calcium is more concentrated in the wall than in the rest of the cell. (*b*) When calcium is severely limiting (histogram *B*) the wall retains a reduced but appreciable amount of this element, sufficient to account for all that is found in the whole cell analysis. (*c*) Magnesium only partly replaces calcium in the wall but fully compensates for deficiency of calcium within the cell (histograms *A*, *B*). In fact, the total divalent cation thus represented by magnesium on a molar basis is significantly greater than when calcium is present as well. On an actual weight basis, Fig. 1 is about the same whether calcium is present or absent. (Total divalent cation in cells receiving calcium, 4·11 mg/g dry cell substance; without supplied calcium, 4·38.)

The apparently more particular relationship between calcium and the cell wall is, we think, significant in relation to the spherical condition of calcium-deprived cells that is quite different from the appearance of cells limited by a shortage of magnesium[4]. It is apparent that each element has a distinct role. Ultra-thin sections of the calcium-deprived cells viewed under the electron microscope show a well-defined double-layered cell wall[4] which is quite different from what we have seen in penicillin-induced spheroplasts of the same organism. Moreover, although the proportion of viable cells grown under con-

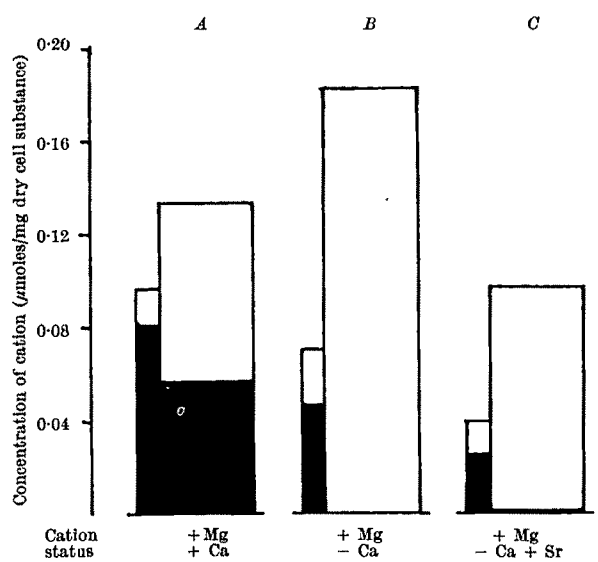

Fig. 1. Distribution of calcium and magnesium between walls and cell interior
In each histogram (*A*, *B* and *C*) the wall, narrow column at the left, is taken to be one-fifth the total cell mass. The height of each column represents concentration; the area, total amount contained in wall or cell
White, magnesium; black, calcium

ditions of calcium deprivation is significantly less than that of calcium-adequate cells[1], we have not been able to demonstrate any marked susceptibility to swelling or osmotic disruption when the deprived cells are suspended in distilled water. Therefore, although their shape suggests some loss of rigidity in the walls, they seem to retain appreciable strength. Any loss of rigidity is not due to absence of the usual '*R*'-layer components[2], and, as has since been found, the cell wall protein of calcium-deprived cells is indistinguishable from the calcium-adequate, either by qualitative analysis of amino-acids or the amount of total protein.

Cell wall calcium was stable to ordinary washing procedures, but 90 per cent of it could be removed readily enough with ethylenediamine tetraacetic acid (EDTA). Whole, non-growing calcium-deprived cells readily took up calcium when exposed to this element for 72 h and attained an internal calcium concentration of the same order as was found in cells grown with a sufficiency of this element ($0{\cdot}06 \times 10^{-3}$ μmoles/μg). Walls of deprived cells made up only half of their deficiency when given the same treatment. These facts, together with our failure to restore normal morphology by subsequent exposure to calcium, seem to indicate that its incorporation into the wall requires calcium to be present when the organism is growing[2].

There is, in fact, other evidence that calcium may be involved structurally in bacterial walls. Keerer and Gray[5] showed that labelled calcium was incorporated into the wall fraction of *Listeria*. Calcium could also be the metal the removal of which by EDTA (and not by several other chelating agents) made a number of Gram-negative species sensitive to lysozyme[6], although the inhibition of lysozyme action by restoring cation seemed to involve a wide range of metals. The EDTA-potentiation of lysozyme in the preparation of spheroplasts[7] could be due to greater exposure of the polysaccharide backbone of the '*R*' layer consequent on the withdrawal of calcium.

So far we have tended to look to the '*R*' layer as a likely site where calcium might exercise a stabilizing role, for example, by neutralizing excessive charges due to carboxyl groups, and thus permit the formation of a tightly packed structure (compare Primosigh *et al.*[8]). In fact, the found calcium seems to be of the order required by the free carboxyl groups in the model for the mucopeptide given by Salton (ref. 3, Fig. 15), taking a value of 10–20 per cent for mucopeptide content of the wall (compare Salton (ref. 3), p. 50). According to these calculations 2 carboxyl groups per mucopeptide unit would require $0{\cdot}1$–$0{\cdot}05 \times 10^{-3}$ μmoles calcium per μg wall, and one carboxyl per unit, $0{\cdot}05$–$0{\cdot}025 \times 10^{-3}$ (found content = $0{\cdot}081 \times 10^{-3}$ μmoles).

It is, however, possible that calcium effects a degree of bonding between '*R*'-layer and the outer lipoprotein, so that it may be a disruption of this, rather than rendering the '*R*'-layer labile, which clears the way for lysozyme action. Similarly deficiency of wall calcium could lead to abnormal morphology. This proposal has something in common with the mechanism of EDTA-potentiation of lysozyme suggested by Noller and Hartsell[9,10] but retains a chelating rather than a detergent role for EDTA. There is no reason for supposing, of course, that other agents could not disrupt the lipoprotein layer for quite different reasons.

Results we have recently obtained with *Rhizobium trifolii* point to calcium as an element that specifically exercises a protective action against the lytic effect of lysozyme (Table 1). Whereas calcium-adequate cells required potentiation by EDTA (columns 1 and 2) those that were deficient in calcium, though having sufficient magnesium (columns 5 and 6), were considerably lysed without the addition of this chelating agent.

Wherever the site of calcium's specific action, the failure of magnesium to replace calcium in the maintenance of normal cell morphology and in the composition of the wall

suggests a structural requirement that magnesium cannot meet. Our further experiments have shown that of the alkaline Earth elements heavier than calcium, strontium, but not barium, can take its place in permitting the development of normal cells, though less efficiently on a molar basis. Growth data (Table 2) showed a similar substitution by strontium (with about one-fourth the efficiency), and columns 3 and 4 of Table 1 again reveal strontium as a substitute for calcium, this time in its protective role against lysozyme.

† In all cases the medium contained 0·5 mM Mg. The second divalent cation was supplied as Ca or Sr (Exp. 1); Ca or Ba (Exp. 2).

Cells deprived of calcium, but normal in morphology as a result of being supplied with strontium, were analysed for calcium and magnesium, with the result shown in histogram *C* of Fig. 1. Strontium not only permitted normal growth and morphology but also evidently replaced some of the calcium that otherwise accumulated in the wall from traces of this element in the medium (histogram *B*). It has also reduced the amount of magnesium substituting for calcium within the calcium-deprived cell.

(We have not so far been in a position to undertake strontium analyses directly, but the foregoing evidence appears to be satisfactorily circumstantial.)

We can use growth and analytical data to test the approximate quantitative relationships between cells and media (Table 3). The trace of calcium known to be in the basal medium (0·003–0·006 μmoles/ml.) is accounted for by that found in the cells, practically all of which is in the walls (column 1 in Table 3). As would be expected, calcium contained in the cells accounts for only a fraction of the calcium supplied by the medium when the latter is in excess (column 2). In this case, however, the amount represented in the cell wall (0·032 μmoles in cells obtained

from 1 ml. of medium) is particularly interesting because it agrees very well with the level on the dose/response curve (ref. 1, Fig. 3) below which the yield becomes dependent on calcium concentration (0·025–0·031 μmoles/ml.). This result again points to the likely importance of calcium in the normal cell wall and the influence it can thereby exert on the growth of the organism.

Beyond the growth-limiting concentration calcium appears in the cell interior, sharing with magnesium a non-specific part that both can play in maintaining sufficient divalent cation. By a similar calculation to those given in Table 3, the cells grown with both calcium and magnesium in excess can be estimated to contain total divalent cation equivalent to 0·25 μmoles/ml. medium. This is within the range of supplied divalent cation in which the total growth responds sharply to concentration of divalent cations (ref. 1, Table 3) and represents considerable concentration within the cells (100–200-fold). Magnesium has, of course, its own specific and quantitatively important role[1].

Our experience with calcium and *Rhizobium* contrasts with that of Wyatt *et al.*[11] with *Staphylococcus*. These authors were unable to show any significant uptake of labelled calcium by a method that would detect removal of $0{\cdot}004 \times 10^{-3}$ μmoles calcium/μg dry cells, an amount very much less than the calcium values we were concerned with. This difference might reflect an association between calcium and lipoprotein in the cell wall of our Gram-negative organism, lipoprotein being absent from the Gram-positive *Staphylococcus*.

The rhizobial cell has specific requirements for calcium and magnesium, each satisfied by a relatively low concentration in the medium. Calcium deficiency is expressed in abnormal morphology (but not a true spheroplast condition), withdrawal of calcium from the cell interior, lowered concentration in the wall, and susceptibility to the action of lysozyme without potentiation by EDTA. A role for calcium in the structure of these walls is thereby suggested. Possibilities are that calcium is involved in stabilizing the '*R*'-layer by bonding with excess carboxyl groups or linking lipoprotein and '*R*'-layer components of the wall. Strontium, but neither magnesium nor barium, can substitute for calcium in its cell-wall function, though less efficiently.

Quantitative relationships between growth and analytical data show that the calcium represented in the walls of deprived cells accounts approximately for the calcium known to be present in the deficient medium. The concentration of calcium below which growth is controlled by this element is close to that concentration at which the cell's need for wall calcium is satisfied.

Calcium shares with magnesium the ability to satisfy the cell's larger non-specific requirement for divalent cations. The total of these within the cell represents considerable concentration from the medium.

PATHWAY OF REDUCTION OF METMYOGLOBIN AND NICOTINAMIDE ADENINE DINUCLEOTIDE PHOSPHATE BY ILLUMINATED CHLOROPLASTS

By Dr H. E. DAVENPORT

University of Bristol, Research Station, Long Ashton, Bristol

In photochemical reductions by isolated chloroplasts the first naturally occurring co-factor to be described was the leaf-protein shown to be highly active in catalysing the reduction of methæmoglobin and metmyoglobin[1]. The 'methæmoglobin reducing factor' was purified[2] and obtained in crystalline form[3], and it has been shown[4] to be identical with 'photosynthetic pyridine nucleotide reductase', a leaf protein fraction found by San Pietro and Lang[5] to mediate the aerobic reduction of substrate amounts of nicotinamide adenine dinucleotide phosphate (NADP) by illuminated chloroplasts. More recently Tagawa and Arnon[6] have described a modified method for preparing the protein and have made further observations on its redox properties. They have concluded that the leaf protein is similar to, but not identical with, an iron-containing protein 'ferredoxin' isolated by Mortenson, Valentine and Carnahan[7] from *Clostridium pasteurianum*, where it was shown by them to serve as an intermediate catalyst between hydrogen, activated by hydrogenase, and a number of hydrogen acceptors.

In experiments where the hydrogenase system in darkness replaced illuminated chloroplasts as a source of reducing power Tagawa and Arnon[6] found that neither the *Clostridium* nor the leaf protein could mediate NADP reduction unless the reaction mixture was supplemented either by chloroplast fragments or a flavoprotein fraction isolated from leaves. From this they concluded that the name 'photosynthetic pyridine nucleotide reductase' is an inappropriate description of the iron-containing leaf protein and they proposed that the name 'ferredoxin' should be extended to this material. This terminology will be adopted in what follows.

It has now been possible to extend the conclusions of Tagawa and Arnon[6] to a reconstructed photochemical system in which illuminated pea chloroplast fragments provide the reducing power and to show that the reduction of metmyoglobin in this system is independent of the presence of protein factors other than ferredoxin. The relative activity of intact pea chloroplasts towards NADP and metmyoglobin has already been described[4]. When such chloroplasts, prepared in isotonic sucrose medium[2], were fragmented and exhaustively extracted by repeated sedimentation from water, they were found progressively to lose their capacity to reduce NADP when illuminated in the presence of adequate amounts of ferredoxin. By contrast, their reactivity towards metmyoglobin increased as a result of the washing (Table 1).

Table 1. The Effect of Successive Water Extractions of Pea Chloroplasts on their Capacity to Photoreduce NADP and Metmyoglobin in the Presence of a Saturating Amount of Ferredoxin

Treatment of chloroplast material	Rate of reduction (μmoles/mg chlorophyll/h)	
	Metmyoglobin	NADP
As prepared in 0·4 M sucrose 0·1 M *tris*-HCl, *p*H 7·8	188	87
Extracted with water:		
twice	220	39
three times	265	25
six times	302	11

Reaction mixtures contained (in 3 ml.) chloroplast material equivalent to 0·03 mg chlorophyll ; pea ferredoxin 0·15 mg and (in μmoles) NADP 0·5 or metmyoglobin 0·025; *tris*-HCl buffer, *p*H 8·0, 150; sodium chloride, 20. Reaction measured as increase in extinction at 340 mμ (NADP) or 582 mμ (metmyoglobin) after successive periods of illumination of 50,000 lux. Gas phase air 20°.

Attempts were made to re-activate NADP reduction by restoring to the assay system protein fractions prepared by ammonium sulphate fractionation of the pooled supernatant fluid obtained in the chloroplast extraction procedure. A fraction precipitated within the limits 50–66 per cent saturation with respect to the salt and then subjected to prolonged dialysis to remove excess ammonium sulphate was found to restore completely the original activity towards NADP, but to be without effect on metmyoglobin reduction. The activity of this fraction towards NADP was destroyed by heating to 80° for 5 min.

Once it had been established that this reactivation could be attributed to protein extracted from the chloroplasts, it was found more convenient to prepare the fraction in quantity from the material which passed through a DEAE-cellulose column when ferredoxin was absorbed in the method described for its preparation by Tagawa and Arnon[6].

Both pea and spinach leaves have been used in the preparation with similar results. The active material was shown by the method of De Luca, Weber and Kaplan[8] to contain flavin-adenine dinucleotide and will be referred to as the flavoprotein fraction.

Using chloroplast fragments depleted of protein by washing, it was then possible to examine ferredoxin and the flavoprotein fraction as two variable quantities required for the reactivation of NADP reduction. In the experiment represented in Fig. 1 all the reaction mixtures contained a sufficient quantity of ferredoxin to saturate the particulate photochemical system. Increasing amounts of added flavoprotein then produced a linear increase in the reduction rate until the system became saturated with respect to this second factor. At the saturation point the rate of reduction, in terms of chlorophyll concentration, is of similar magnitude to those obtained with freshly prepared intact pea chloroplasts where ferredoxin is the only catalytic factor required. With high concentrations of the flavoprotein in the reconstituted system, dark reoxidation of reduced NADP became significant. The extent of the reactivation of the photochemical reaction can be better appreciated in the curve in Fig. 1 to which corrections have been applied to take account of this dark reaction.

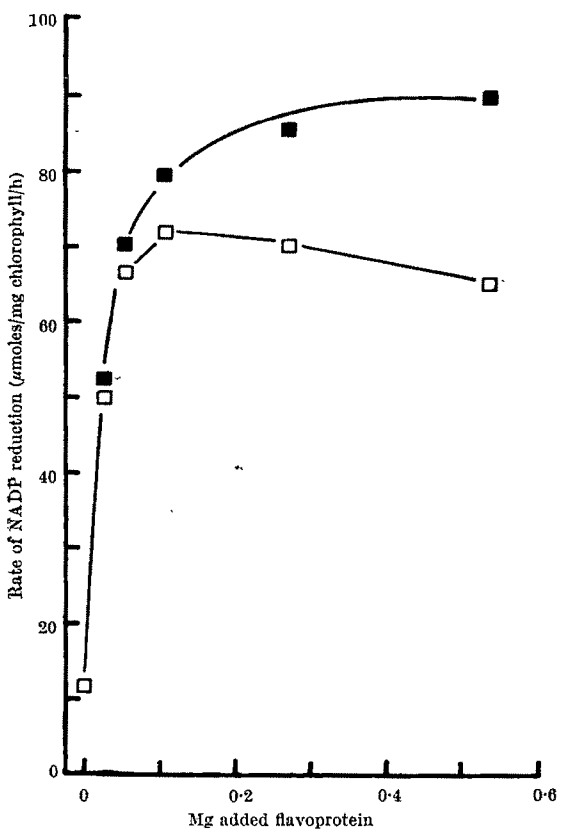

Fig. 1. Activity of pea-leaf flavoprotein fraction in restoring the capacity of protein-depleted pea chloroplast fragments to photoreduce NADP in the presence of saturating concentration of ferredoxin. Experimental conditions as for NADP reduction in Table 1 except that each cell contained pea chloroplast fragments extracted six times with water and equivalent to 0·025 mg chlorophyll. □, Experimental; ■, corrected for dark oxidation

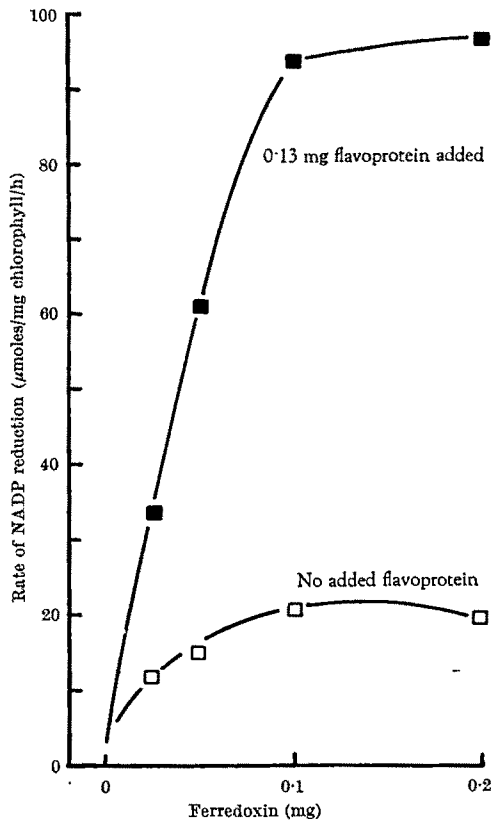

Fig. 2. Activity of pea ferredoxin in mediating NADP photoreduction by protein-depleted pea chloroplast fragments. □, With no further additions; ■, in the presence of a saturating amount (0·13 mg) of a pea-leaf flavoprotein fraction. Experimental conditions as Fig. 1

In a second series of experiments the level of ferredoxin was varied in the presence and absence of a saturating amount of the flavoprotein fraction. The result, shown in Fig. 2, confirms that both leaf proteins must be restored in saturating amounts to the washed chloroplast system for maximum reactivation of NADP reduction to be attained.

A further line of evidence that a factor additional to ferredoxin is involved in the photoreduction of NADP by intact chloroplasts was obtained by the use of organic mercurial compounds as selective inhibitors of this additional factor *in situ* within the chloroplast. It has already been shown that mercury compounds inactivate ferredoxin[2]; their inclusion in the reaction mixture would therefore not be expected to produce differential inhibition of metmyoglobin and NADP reduction. In order to localize the action of the heavy metal, pea chloroplasts

Table 2. The Effect of Treating Intact Pea Chloroplasts with Phenyl Mercury Acetate on their Capacity to Photoreduce NADP and Metmyoglobin

Chloroplast treatment	Rate of reduction (μmoles/mg chlorophyll/h) Metmyoglobin	NADP
Untreated	168	60
Treated with PMA	170	20
Inhibition (%)	0	66

Reaction mixtures as Table 1 except that chloroplasts contained 0·045 mg chlorophyll.

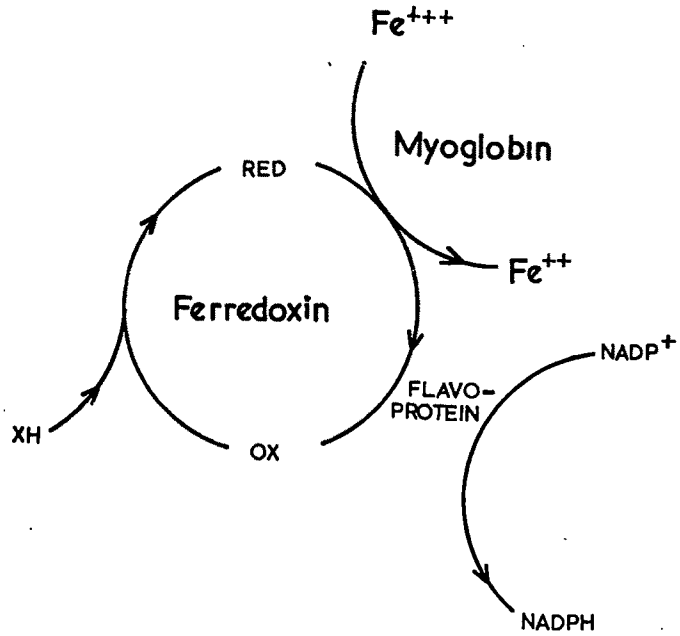

Fig. 3. Diagrammatic representation of the reduction of NADP and metmyoglobin by illuminated chloroplasts

which had been prepared and washed once in isotonic sucrose, and which were therefore substantially free from ferredoxin, were incubated for 5 min in the sucrose medium containing 5×10^{-4} M phenyl mercury acetate, (PMA). Excess PMA was removed from the chloroplasts by two further washes with the sucrose medium and their photochemical activities were compared with those of pea chloroplasts which had undergone a similar sequence of washes in sucrose alone. Table 2 shows that the ferredoxin-catalysed reduction of metmyoglobin was unaffected by the treatment with PMA whereas reduction of NADP underwent a 66 per cent inhibition, suggesting that the mercury was reacting at a site in the chloroplast essential for NADP but not for metmyoglobin reduction.

Although results similar to those in Table 2 have been obtained with chloroplasts prepared from spinach (*Spinacea oleracea*) these proved to be less satisfactory than pea chloroplasts in the type of experiment summarized in Table 1. It appeared that, whereas ferredoxin is readily released into the suspending medium from the chloroplasts of both genera, the flavoprotein is held more tenaciously by the spinach chloroplasts.

The extracted flavoprotein has the properties of a partially purified preparation of the $NADPH_2$-specific diaphorase extracted by Avron and Jagendorf[9] from spinach chloroplasts. In addition to the range of electron acceptors listed by these authors, it was found to mediate the reduction of pyocyanine and, in a nitrogen atmosphere, 1,1′-ethylene-2,2′-dipyridylium dibromide($E'_0 = -349$ mV). It has not yet been possible to demonstrate a net reduction of ferredoxin but, in the presence of this protein, or of pyocyanine, the flavoprotein actively mediates the reduction of metmyoglobin when $NADPH_2$ serves as hydrogen donor. Lazzarini and San Pietro[10] have reported a similar activity where a preparation of spinach leaf transhydrogenase, possessing diaphorase activity, was found to mediate the reduction of cytochrome *c* by $NADPH_2$ only in the presence of ferredoxin. Attempts to demonstrate transhydrogenase activity in the pea flavoprotein fraction, using the assay method of Keister and San Pietro[11], have not been successful.

The foregoing observations are consistent with the proposals of Tagawa and Arnon[6] for the electron transport pathway leading to the photochemical reduction of NADP. The position of metmyoglobin in the sequence of reductions is expressed diagrammatically in Fig. 3.

CYTOCHEMICAL MEASUREMENT OF PROTEIN SULPHYDRYLS IN CELL LINES OF DIFFERENT RADIOSENSITIVITY

By OLLE CASPERSSON and LÁSZLÓ REVÉSZ

Institute of Cell Research and Genetics, and Institute of Tumour Biology, Karolinska Institutet Medical School, Stockholm

THE method for histochemical detection of protein-bound sulphydryl groups by 2,2′-dihydroxy-6,6′-dinaphthyl disulphide (DDD) was introduced by Barrnett and Seligman in 1952 [1,2]. They showed that the disulphide of this compound reacts with protein sulphydryls at an alkaline *p*H. The chromogenic naphthol moiety, transferred to the protein, becomes part of the reaction product, and is readily converted to a coloured azo product by either tetrazotized diorthoanisidine[1,2] or diazotized 4-amino-3,6-dimethoxy-4′-nitroazobenzene (*Echtschwarzsalz*)[1]. The reactions, accomplished according to the procedure developed by Barrnett and Seligman, were shown[2,3] to be specific for protein-bound sulphydryls. Based on the results of a series of methodological experiments using *Echtschwarzsalz*, Bahr[4] concluded the method to be suitable for quantitative histochemical work at a cellular level.

Microspectrographic measurements of the amount of protein sulphydryls in individual cells, as revealed by Bahr's procedure, using DDD in combination with *Echtschwarzsalz*, were carried out in closely related tumour cell lines of different radiosensitivity. A hyperdiploid Ehrlich ascites tumour, denoted *ELD*, with a modal chromosome number 46 and an average DNA content of $11{\cdot}2 \times 10^{-9}$ mg/cell, and its three sub-lines were used. The sub-line *ELT* represents the hypertetraploid clonal population of an endoreduplicated cell, isolated from *ELD*, and has a modal chromosome number 92 and an average DNA content of $20{\cdot}5 \times 10^{-9}$ mg/cell. *SELD* clone *g* and clone *j* originated from single cells, which were isolated from *SELD*. *SELD* was derived from *ELD* by serial irradiation of the cells with sub-lethal X-ray doses during the course of 23 intraperitoneal passages. Both *SELD* clones had a modal chromosome number 45. The average DNA content was 11·32 (clone *g*) and 10·99 (clone *j*) $\times 10^{-9}$ mg/cell. The details of the isolation of the clones and several characteristics of the cell lines, including the growth characteristic, chromosomal variation, radio-

sensitivity, DNA and non-protein sulphydryl content, have been examined, and are described in previous reports[6–9].

Smears were prepared from freshly withdrawn ascites 7–12 days after the intraperitoneal inoculation of the respective tumour into hybrid mice, and fixed and stained according to the method already referred to[4].

The total extinction of individual cells was measured at 5800 Å in a rapid-scanning universal ultramicrospectrograph[5]. The instrument was fitted with Zeiss achromatic ultra-violet optics.

Fig. 1 shows the frequency distribution of the total extinction of individual cells at 5800 Å of four separate *ELD* populations. The term 'total extinction' refers to the total amount of absorbing material within the cell at the wave-length used. One hundred cells were measured in each of two populations (populations I and II), and 50 in each of the two other populations (III and IV). It can be noted that the values of all four populations are distributed within a closely similar range between 10 and 70, with means varying between 36·9 and 44·6. The distributions seem to approach the shape of normal distribution curves with the exception of population III, the curve of which shows an extra peak near the doubled mean value.

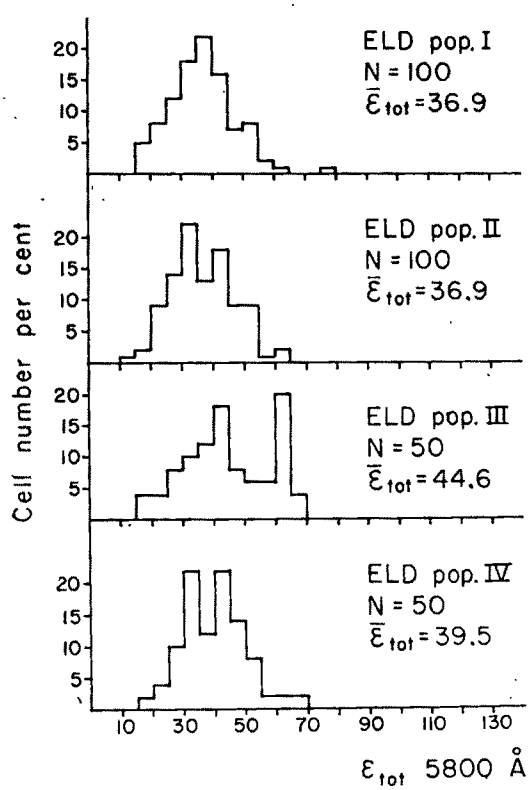

Fig. 1. Frequency distribution of the total extinction of individual cells at 5800 Å in DDD-*Echtschwarzsalz* stained specimens of four separate *ELD* populations obtained, fixed and stained at different times

Fig. 2 shows the frequency distribution of the total extinction of individual cells at 5800 Å of the different cell lines examined. The upper curve is the total of *ELD* populations I–IV already mentioned. The two middle curves show the distribution of single populations of the two *SELD* clones. The lower curve was obtained by measuring two separate *ELT* populations of 100 cells each. A comparison of the frequency diagrams indicates that the distribution pattern and the means of the *SELD* clones are closely similar to that of *ELD*. The *ELT* values, however, are distributed over a range which is roughly twice that of the other populations (25–150) and the mean value of 64·6 is 1·6 times larger than the other mean values.

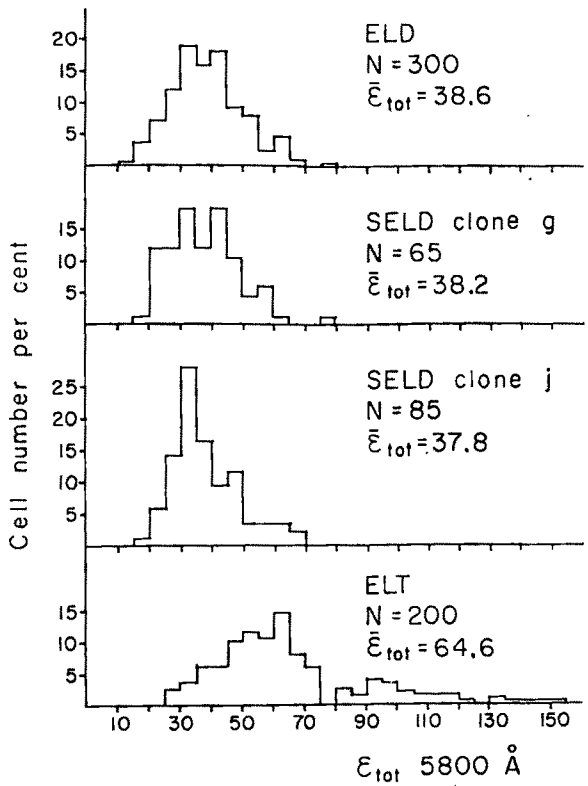

Fig. 2. Frequency distribution of the total extinction per cell in DDD-*Echtschwarzsalz* stained specimens of the pooled values of four separate *ELD* populations shown in Fig. 1, and of three *ELD* sub-lines: *SELD* clone *g*, *SELD* clone *j* and *ELT*. Each of the two *SELD* frequency distribution curves represents a single population, whereas the *ELT* curve represents a combination of two separate populations

The good reproducibility of the data of repeat experiments shown in Fig. 1 can be considered as indicating the suitability of the method for quantitative cytochemical investigations. The total extinction values indicate, furthermore, that the protein sulphydryl level is of a closely similar magnitude in the two *SELD* clones and the parental *ELD* line, but is nearly duplicated in the *ELT* sub-line with a doubled genome. There appears, thus, to exist a direct relationship between the protein sulphydryl level and the modal chromosome number or the average amount of DNA of the cell lines. The elevated protein sulphydryl level of *ELT* is in conformity with previous observations that the doubled genetic material in these cells is associated with a 1·6–2-fold increase of the amount of several enzymes, total lipid fatty acids, cholesterol and non-protein sulphydryls[6,7,9,10].

Since the average non-protein sulphydryl content per cell in *SELD* clones *g* and *j* is, as previously reported[9], 24 and 34 per cent larger, respectively, than in *ELD*, the results imply an increased non-protein sulphydryl/protein sulphydryl ratio in the *SELD* clones as compared with *ELD* or *ELT* (Table 1). Considering the radioprotective effect of low molecular thiol compounds[11], it is conceivable that the increased non-protein sulphydryl concentration per unit protein sulphydryls, as well as per

Table 1. Relationship between the Average Cellular Content of Non-protein-bound and Protein-bound Sulphydryl Groups; and the Average Cellular Content of Non-protein-bound Sulphydryl Groups and Deoxyribonucleic Acid (DNA) in Three Radio-resistant Sub-lines (*ELT*, *SELD* Clones *g* and *j*) of the *ELD* Ascites Tumour

ELD sub-lines	*ELT*	*SELD* clone *g*	*SELD* clone *j*
Non-protein sulphydryls / Protein sulphydryls	1·08	1·25	1·37
Non-protein sulphydryls / Deoxyribonucleic acid	0·99	1·22	1·37

(The figures indicate the values relative to *ELD*, and have been calculated from the data presented in Fig. 2 and in a previous publication (ref. 9).

unit DNA, may result in an increased protection of the function and structure of proteins and genetic material against radiation. This would explain the greater resistance of the serially irradiated *SELD* sub-lines relative to the original *ELD* line, to the growth inhibitory effect of anoxic X-irradiation[8]. Since, in contrast, the non-protein sulphydryl concentration per unit protein sulphydryls or DNA is of a closely similar magnitude in *ELD* and *ELT*, another explanation may be relevant for the relative radio-resistance of the latter line[7]. Considering the dominant role of damage to the genetic material in determining the cytocidal effect of radiation[10,12], the possible requirement to inactivate a larger number of homologous, sensitive sites in the exactly duplicated genome of *ELT* may account for radio-resistance in this case, as suggested previously[8].

QUANTITATIVE RELATIONSHIPS IN TUMOURS INDUCED BY A VIRUS, AND BY OTHER AGENTS

By Prof. HAROLD F. BLUM

National Cancer Institute, Bethesda, Maryland, and Department of Biology, Princeton University, Princeton, New Jersey

BRYAN'S investigations[1,2] on the Rous sarcoma (chicken tumour 1) provide quantitative data which permit the formulation of a model that may shed light on the mechanism of action of carcinogenic viruses. Bryan finds the relationship:

$$\frac{1}{t_d} = b \log M \qquad (1)$$

where M is the dose of virus, t_d the time from dosage to appearance of tumour, and b a constant. The time to appearance of tumour represents growth from an unmeasured initial volume, V_0, to an observed volume, V_d (approx. 1 mm^3); hence the reciprocal of t_d is a measure of the growth rate of the tumour. The production of virus follows a similar dose-response curve[3].

Growth of tumours depends basically on cell proliferation by duplication of cells. In normal tissues the increase in number of cells is nicely balanced by destruction of cells; but if proliferation exceeds destruction, tumours must form. Although Eversen and Iversen[4] suggest that tumours could result from decrease in destruction of cells without increase in rate of proliferation, this would not account for fast-growing tumours such as are dealt with here, and for various reasons is unlikely in most cases[5]. Thus, it seems safe to assume that in the course of growth of tumour the rate of proliferation is more rapid than it is in normal tissues. The information which directs the duplication of cells and their parts must be carried in templates which are themselves replicated in cell division; and information determining the basic rate of cell division must be one of the things carried, although extraneous factors may, of course, have transient effects on rate.

Viruses depend for their replication on the cell into which they are introduced. The virus provides the template according to which it is replicated; but the work of replication is paid for in terms of the metabolism of the cell, by means which the virus itself lacks. The greater the number of virus particles replicated by the cell, the greater the load on cell metabolism, which must have definite limits. Thus, the rate of replication of virus templates, r, may be expected to increase in inverse proportion to the number present, and since the number introduced is proportional to the dose M, we may write:

$$dr = \frac{dM}{M} \qquad (2)$$

and:

$$r = \log M + \log C \qquad (3)$$

The rate of cell proliferation R is proportional to the number of cells, and hence to the volume of the tumour. Thus:

$$R = \frac{dV}{V dt} \qquad (4)$$

Those viruses which produce tumours must increase the rate of cell proliferation, so we may assume that this is proportional to the number of particles in the cell. The increase in rate of cell proliferation entails further load on the machinery of replication, pushing it toward the limit of its capacity that is implied in expression (2). Thus we may substitute, introduce appropriate constants and integrate to obtain:

$$\log \frac{V}{V_0} = gt \log qM \qquad (5)$$

where g represents the assumed proportionality between rates of virus and cell proliferation, and q represents the proportionality between dose and number of virus particles.

Experimentally, comparison at time t_d is made at the constant volume V_d, and if we may assume that V_0 is also constant, as would be the case if the tumour grew, say, from a single cell, the left-hand term in expression (5) may be replaced by a constant k. Then substituting and rearranging:

$$\frac{1}{t_d} = \frac{g}{k} \log qM \qquad (6)$$

which corresponds to expression (1). The model appears compatible with the experimental findings.

It should be noted that, since M has been held constant during the integration to obtain expression (5), it is implied in the model that the number of virus particles is the same for each tumour cell as the number originally introduced into the parent cell. In other words, the cell appears to replicate the virus particles as though they were templates of the cell itself, for example, genes. Since the carcinogenic viruses increase the rate of proliferation of tumour cells, which might be a principal characteristic that distinguishes them from other viruses, it would seem that their proportional replication with each cell division would be essential. Bryan's finding[3] that the amount of extractable virus per unit of tumour volume is greater for fast-growing tumours, and that the relationship parallels quantitatively that described in expression

(1), adds further support for the model, since faster-growing tumours should be those which received the greater initial infection.

The model presents a very different picture from the run-away replication of viruses, such as might be expected for, say, bacteriophage, which would not at all satisfy the relationship indicated in (1); the replication of prophage might, however, follow this model. On the other hand, the latter relationship (1) is paralleled in the development of mouse encephalitis[6].

When the virus particles are introduced into the tissues we may expect many cells to be infected, but with different numbers of particles, according to chance distribution. Thus, a number of clones should be formed, the cells of which proliferate more rapidly than do the uninfected cells of normal tissue; but only the more rapidly growing of these clones would contribute importantly to the growth of the tumour. At high doses the growth of these tumours is so rapid, on the other hand, that it is unlikely they arise as a single clone. It might be expected that the number of cells infected would be proportional to the dose, that is, V_0 would be proportional to M; but from inspection of expressions (5) and (6) it is seen that this should not change the relationship essentially, and that there would still be agreement with the experimental findings[1]. This would not be true if tumour cells were recruited by further infection during tumour development; but it seems unlikely that this was an important factor in these experiments, since it would be difficult in that case to account for the quantitative relationships observed for both tumour development and extractable virus. Recent experiments of Bergs and Groupe[7] also indicate that tumour growth depends on the magnitude of the initial infection.

The induction of tumours by ultra-violet light, which requires many repeated doses, presents a very different quantitative picture describable by:

$$\log \frac{V}{V_0} = \frac{sUt^2}{i} \qquad (7)$$

where s is a constant, U the individual dose of ultra-violet light, and i the interval between doses. This and other relationships found for these data indicate that the rate of cell proliferation is increased at every repetition of dosage, and that we deal, here, with a cumulative process[5].

Dose-response relationships for induction of tumours by chemical agents appear to be quite different from those for ultra-violet light or virus carcinogenesis; they are approximately described in form corresponding to expressions (5) and (7) by:

$$\log \frac{V}{V_0} = wA^xt \qquad (8)$$

w and x having different values according to the carcinogen and probably the animal. Up to now no satisfactory model agreeing with these data has been formulated[8,9].

A consideration of quantitative relationships (5), (7) and (8) indicates that the mechanisms for the corresponding three types of carcinogenesis are very different; and that the rather current idea that all neoplasms may be attributed to virus is not tenable. There would seem, in this, support for the idea that different kinds of cancer may be looked on as different diseases[10,11]. One still searches, however, for a common denominator in terms of transfer of information in the proliferation of cancer cells, whether regarded as autonomous or not.

MUSCLE BIOPSY IN MAN: AN INDEX OF CELLULAR POTASSIUM?

By Dr. C. T. G. FLEAR and IRENÉ FLORENCE
Queen Elizabeth Hospital, Birmingham

CELLULAR deficiency of potassium arises clinically. It may do so acutely or insidiously and in either event compromises the patient's condition. Diagnosis may be difficult; certainly the serum level is unreliable as an index of cellular content.

Potassium in the extracellular phase of muscle usually makes up less than 2 per cent of the total. Even in the presence of a raised serum potassium, excess extracellular fluid and gross cellular depletion of potassium it is still less than 5 per cent of the total. The potassium content of a biopsy is therefore a good index of its cellular potassium, but does it also afford useful information about the cellular content of potassium throughout the rest of the muscle? In a wide range of circumstances, analytical results for a single slice of rat muscle afford reliable information about the muscle sampled, other muscles, and also other tissues[1]. Is this also true for man? Certainly it is often presumed to be the case.

Analysis yields values for composition in terms of amounts per weight of tissue sample analysed, and biopsies may well contain differing proportions of their various components—muscle cells, nerve cells, fibroblasts, connective tissue fibres, ground substance, blood vessels and blood cells, extracellular water and fat. Fortunately in an adult, cells other than muscle fibres make so insignificant a contribution to the cellular phase that this may be regarded as consisting wholly of muscle cells and any effect on its average composition in a biopsy which might result from differences in the ratio of muscle cells to fibroblasts and other cells can safely be ignored. Nevertheless, the potassium content of a biopsy will be affected by the relative proportions of cellular, extracellular phases, and fat, as well as by variation in average composition of muscle cells between different samples. We may further consider that a biopsy sample taken from a patient's muscle is, weight for weight, a very much smaller proportion of the total muscle sampled than in the rat. One might therefore expect, in man, greater variability between samples taken from the same muscle than in the rat. Our studies confirm this expectation. Despite this, however, we have concluded that, properly interpreted, a biopsy can appraise one of cellular potassium throughout the muscle sampled, and in other muscles too, albeit the latter with somewhat less precision. Evidence for these conclusions are summarized here.

Three widely separated locations were sampled from muscles exposed at the beginning of operations in a number of subjects. In most subjects only one muscle was sampled; in some 3, 4, or 5 muscles were sampled. Three slices, of about 20 mg weight, were cut from each sample and analysed for water, fat, and electrolytes using the method previously described[2]. The anterior muscles

of the thigh were sampled severally in three rats. Slices were also cut serially from the right anterior tibial muscle of one rat, and triplicate slices were cut from anterior tibial muscles in 28 male rats from 2–15 months old. All samples were analysed for water and electrolytes using this same method ; fat content was not determined.

From these results coefficients of variation (per cent) were derived to describe the variability in human material of potassium within one location of a muscle, that within a whole muscle, the overall variability within and between several muscles in an individual, and the variability obtaining when samples from the same muscle, but different individuals, are considered. For the rat, coefficients of variation were calculated[1] which define variability of potassium within one location of a muscle, that within a whole muscle, and that between several muscles.

None of the subjects, data for whom are considered here, had overt abnormalities of water and electrolyte metabolism; none had neuro-muscular disorders.

Table 1 presents the coefficients of variation of a single estimate of muscle potassium obtaining when it is used as an index of composition in the immediate vicinity of the sample, throughout the whole of the muscle sampled, of other muscles in the same subject, or of the composition to be expected for the particular muscle sampled but in other similar subjects. For comparison similar information is presented in Table 1 for rat muscle.

Table 1. VARIABILITY IN POTASSIUM CONTENT OF SKELETAL MUSCLE IN MAN AND, FOR COMPARISON, RAT

Variability		Man	Rat
One individual	One location one muscle	5·8	2·6
	several locations one muscle	8·1	3·4*
	several locations several muscles	13·1	4·2*
Several individuals	Several locations one muscle	12·0	5·0

* Reference no. 1.

Values are coefficients of variation (per cent) for a single estimation. They were calculated when potassium content was expressed as m.equiv./kg wet wt. of muscle.

Differences in the proportion of fat in samples will promote variability in their potassium content. It has been suggested that this is the major source of differences in potassium content of muscle[3]; but differences in the fat content of samples did not contribute much to the variability of potassium occurring in man (Fig. 1). The samples of human muscles were all taken from inside muscles and did not therefore include fat on their outer surfaces; unlike the dog muscles, analysis of which underlay the emphasis on differences in fat as the major source of differences in potassium content[4]. Nevertheless, it would be a mistake to ignore differences in fat content of samples taken as ours were from within muscle, as a source of variation in their potassium content, for we gain in understanding if potassium content is related to the content of tissue solids, and, as will be apparent from Fig. 4 evaluation, when so related, is blunter if fat content is not known. If we examine the findings in individual subjects, it is of course necessary to know the fat content of samples, for, even when all fat is apparently removed before analysis, considerable amounts may remain. In our hands as much as 16 per cent by wet weight has occasionally persisted. It is therefore gratifying that defatting does not increase errors (Fig. 1).

Differences in water content of samples would promote variation in the amount of potassium associated with a given wet weight of muscle, say 1 kg, even when the extra water is unaccompanied by potassium; they would, however, leave unaffected the amount of potassium associated with 1 kg of fat-free tissue solids. Referring potassium content to 1 kg fat-free tissue solids did not appreciably lessen variability in potassium (Fig. 2), so that this source, too, does not make much contribution to differences in potassium content of samples from control subjects. This is perhaps not surprising since, in view of the osmotic

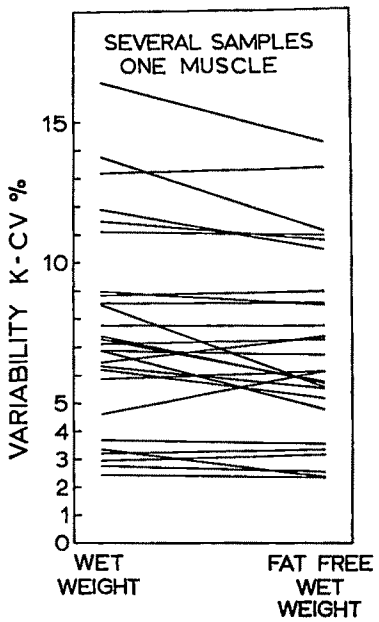

Fig. 1. Variability in the potassium content of different samples taken from the same muscle, showing the relatively small contribution made by differences in their fat content. Variability is presented as coefficients of variation when potassium content is given as m.equiv./kg of wet tissue and as m.equiv./kg of fat-free wet tissue. Each coefficient of variation is based on analyses of 6 (5 instances) or 9 (22 instances) samples from a given muscle in one subject

equilibrium across cell membranes, differences in water content of samples are unlikely, when cellular in origin, to arise in the absence of change in cell solutes—including potassium.

Neither differences in fat nor water content of samples could be responsible for the striking negative correlation encountered between the sodium and potassium contents of samples of human muscle. This is present when samples are taken from within the one muscle in the same, or different, individuals (Fig. 3); when they are from several muscles in the same individual (Fig. 3), or from different individuals (Fig. 3). The relationship is present, moreover, when potassium and sodium contents of samples are expressed as m.equiv./l. tissue solids, m.equiv./kg wet, or fat-free wet-wt., and also when expressed as m.equiv./kg fat-free dry wt. of tissue. It is absent when data are expressed as m.equiv./kg dry wt. of tissue (Fig. 4). In passing it may be mentioned that we did not find a negative correlation between the con-

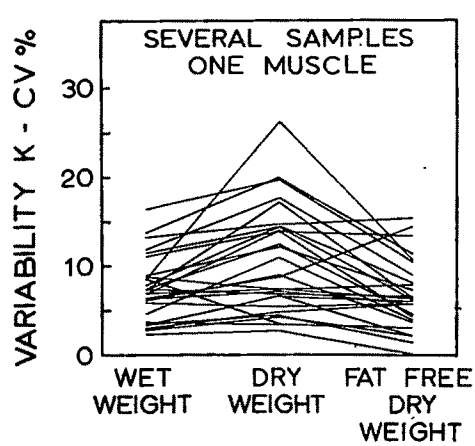

Fig. 2. Variability in the potassium content of different samples taken from the same muscle, showing the relatively small joint contribution made by differences in fat and water contents. Variability is presented as coefficients of variation when potassium content is given as m.equiv./kg of wet tissue, per kg dry wt. of tissue, and per kg fat-free dry wt. of tissue. Material presented in Fig. 1 forms the basis of this figure also. Each coefficient of variation is based on analyses of 6 (5 instances) or 9 (22 instances) samples from a given muscle in one subject

tents of potassium and sodium in samples of rat skeletal muscle (Fig. 5).

Cellular fluid is rich in potassium with but little sodium; the opposite is true for extracellular fluid. It follows that a sample with relatively more extracellular fluid will contain more sodium and less potassium than a sample with relatively less extracellular fluid, and vice versa. Differences in the amount of extracellular fluid associated with a given wet weight of tissue would arise were the average diameter of muscle fibres in samples to differ. Fourman has pointed out[5,6] that thin fibres will have a relatively greater surface film of extracellular fluid than fat ones. Variation in average diameter of muscle fibres in samples would thus occasion a negative correlation between sample contents of sodium and potassium when quoted as m.equiv./kg wet wt. of tissue, per kg fat-free wet wt., or per litre of tissue water. Unless thin fibres contain proportionately more solids than fat ones, or unless samples with a higher proportion of thin fibres also contain relatively more connective tissue, whence extracellular solids, contents of sodium and potassium will not, however, exhibit a negative correlation when 1 kg fat-free tissue solids is the reference base used. Its existence (Fig. 4) could thus be accounted for. Our findings (Figs. 3 and 4) could also be explained if the average composition of cellular fluid varied from sample to sample if it be

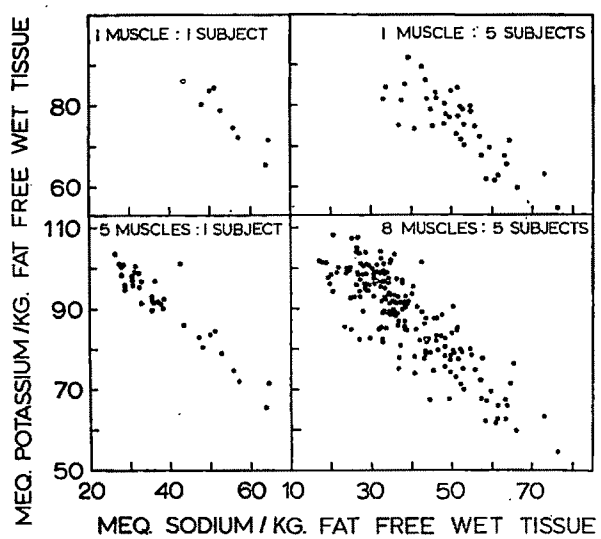

Fig. 3. The sodium and potassium contents of samples of human muscle are presented in this figure as m.equiv./kg fat-free wet wt. of tissue. A striking negative correlation exists between contents of sodium and potassium; samples with a lot of potassium have little sodium, and vice versa. This relationship obtains whether samples are all taken from the same or different muscles in an individual, whether from the same muscle but different subjects, or indeed from a number of different muscles as well as different subjects. This relationship is also present when results are expressed as m.equiv./kg wet wt. of tissue, m.equiv./l. of tissue water, or m.equiv./kg fat-free dry wt. of tissue

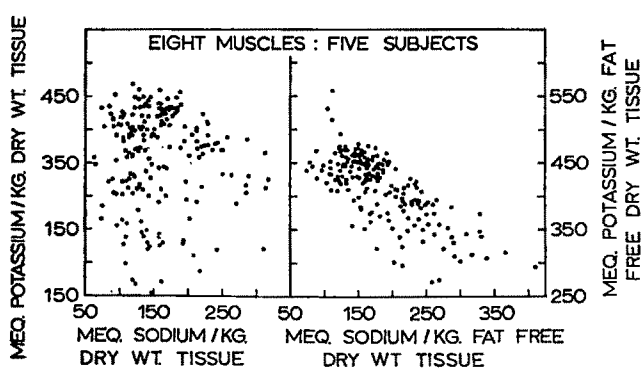

Fig. 4. Sodium and potassium contents of samples of muscle from eight different muscles, four or five of which were sampled in each of five individuals. Contents were expressed both as m.equiv./kg dry wt. of tissue and per kg fat-free dry wt. of tissue

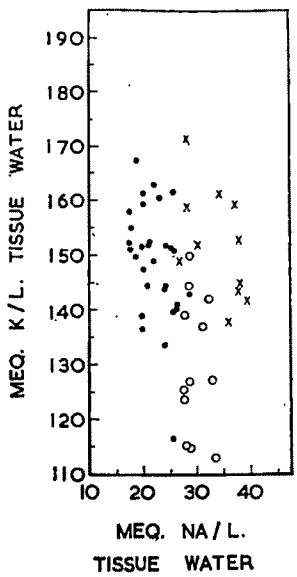

Fig. 5. The sodium and potassium contents of samples of the anterior muscles of the thigh in three healthy rats are shown in this diagram. They are presented as m.equiv./l. of tissue water as fat was not determined; essentially the same findings are noted when presented as m.equiv. kg wet wt. of tissue. The relationship seen in man between sodium and potassium contents is absent

allowed that cells containing more sodium contain less potassium and vice versa. For reasons submitted in outline elsewhere[7] we believe this to be the more important source of differences met in the potassium content of samples.

Whatever the cause of the very striking negative correlation between the potassium and sodium contents of human muscle, but for its existence one would be forced to the reluctant conclusion that biopsies afford an imprecise index of composition within muscles sampled. As it is, the coefficient of variation of a single potassium estimate, used as such an index, reduces from 8 to 5 per cent, when the sodium content is also considered. When account is also taken of the fat content it reduces still further to 4 per cent (Table 2). When used as an index of composition in other muscles of the body, the corresponding reductions in the coefficient of variation of a single potassium estimate are 13–8·5 per cent when account is taken of sodium, to 5·7 per cent when fat is also considered (Table 2). The possibility that greater variability in composition of muscle exists in patients with pronounced electrolytic or other systemic disturbances is being investigated.

Table 2. Variability in Potassium Content of Skeletal Muscle in Man; Coefficients of Variation (per cent) of an Individual Potassium Estimation, when Account is also taken of the Sodium Content of the Sample

		Reference base: 1 kg wet wt.	Reference base: 1 kg fat-free wet wt.
One individual	Several locations one muscle	5·0	3·9
	Several locations several muscles	8·5	5·7
Several individuals	Several locations one muscle	8·1	6·1

Data from which these values were calculated were expressed either as m.equiv. potassium per kg wet wt., or per kg fat-free wet wt. of tissue.

ISOLATION AND CHARACTERIZATION OF MURAMIC ACID FROM TWO SPIROCHÆTES: *BORRELIA DUTTONI* AND *LEPTOSPIRA BIFLEXA*

By C. D. GINGER

Department of Chemotherapy and Parasitology, National Institute for Medical Research, London, N.W.7

THERE is considerable confusion about the nomenclature and taxonomic position of helical, motile micro-organisms. Some are definitely classified with the bacteria (Spirillaceae)[1], others (Spirochaetales), with either the bacteria[1] or the Protozoa[2], and it has been suggested that certain members of the Spirochaetales should be classified with the Cyanophyceae[3].

One biochemical character which has proved useful in bacterial classification is the presence of cell wall mucopeptides, which on hydrolysis give a small range of sugars and amino-acids together with the amino-sugars glucosamine, galactosamine and muramic acid[4]. Apart from the true bacteria, muramic acid has been found only in the Actinomycetales[5] Cyanophyceae[6] and Rickettsiae[7]. The purpose of this article is to report that muramic acid has been isolated and characterized from two members of the Spirochaetales; *Borrelia duttoni*, the spirochæte of relapsing fever, and *Leptospira biflexa*, a free-living spirochæte found in natural waters.

B. duttoni is an old laboratory strain, maintained in young rats by syringe passage. Parasites were collected by bleeding the rats at the height of the first parasitæmia and were then separated from the blood by differential centrifugation. *L. biflexa* was cultured in Korthof's medium with added hæmoglobin, yeast extract and rabbit serum, and concentrated by centrifugation. The organisms were thoroughly washed and freeze-dried, and after extraction of lipids were treated by the method of Cummins and Harris[8] for isolation of mucopeptide from cell walls. Ribonuclease digestion was replaced by extraction of ribonucleic acid with 0·3 N potassium hydroxide for 5 h at 37° C, and deoxyribonucleic acid was extracted with 5 per cent trichloroacetic acid for 30 min at 70° C. The dried residue was hydrolysed in a sealed ampoule with 4 N hydrochloric acid for 4 h at 105° C, and dried *in vacuo* over potassium hydroxide. Muramic acid was identified in this hydrolysate by two-dimensional paper chromatography using *n*-butanol/pyridine/water (6:4:3) and *n*-butanol/acetic acid/water (63:10:27) as solvents, and spraying with ninhydrin reagent. Muramic acid was isolated from the remainder of the hydrolysate by concentration of amino-sugars on a 'Zeokarb 225 (H^+)' column, followed by further separation of muramic acid from glucosamine on a mixed 'Norit'/'Celite' column[9].

Part of the material obtained in this way was chromatographed on paper in the *n*-butanol/acetic acid/water system, together with standard preparations of glucosamine, galactosamine and synthetic muramic acid. The spirochæte material showed a spot which had the same mobility as muramic acid, and which gave positive reactions with ninhydrin and the Elson–Morgan[10] reagents. The remainder of the column eluate was finally purified by preparative paper chromatography in the same solvent system, which removed other faint ninhydrin-positive spots having greater mobility than muramic acid. The purified material eluted from the paper gave a chromogen in the Rondle and Morgan reaction[11] which had all the properties of the muramic acid chromogen[12], that is, the absorption maximum, if read immediately, was at 510 mμ and after 24 h at 505 mμ, with an approximate two-fold increase in intensity (Fig. 1). The substituted pentose obtained by treatment of the sample with ninhydrin[13] was identical in both colour and mobility with that obtained from synthetic muramic acid, when subjected to paper chromatography in *n*-butanol/pyridine/water, and sprayed with anisidine hydrochloride reagent[14].

This demonstration of muramic acid in the Spirochaetales suggests that they have a cell wall similar in structure to that of the bacteria, and provides support for their classification in this group, and not in the Protozoa. Other characters, which also point to their bacterial nature, are their general morphology, with a distinct cell wall and capsule[15], resistance to nuclear staining[16] and sensitivity to antibiotics[17] and to lysozyme[18]; these last two characters are presumed to be a consequence of the muramic acid content[4,19].

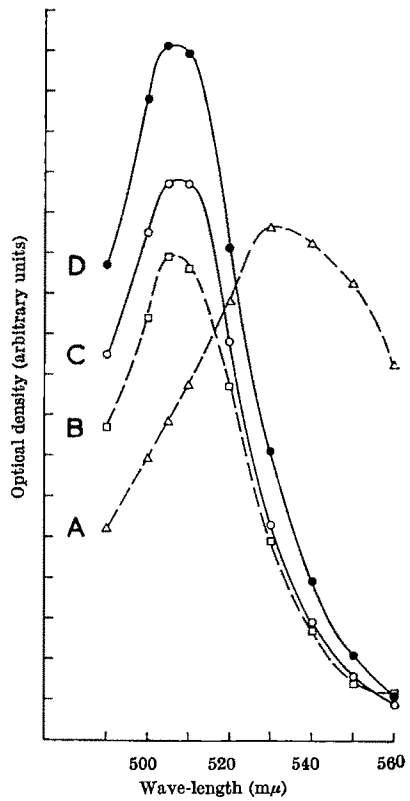

Fig. 1. Absorption spectra of the chromogens obtained in the reactions for amino-sugars described by Rondle and Morgan[11]. *A*, 20 μg of glucosamine, readings taken immediately; *B*, 20 μg of synthetic muramic acid, readings taken after 24 h; *C*, material from *B. duttoni*, readings taken after 24 h; *D*, material from *L. biflexa*, readings taken after 24 h

I thank Dr. R. H. Gigg for the synthetic muramic acid. Dr. J. D. Fulton for the two strains of spirochaetes with details of their growth, and Dr. H. R. Perkins for helpful discussion.

APPARENT RELATIVE MOVEMENT OF 'UNSHARP' AND 'SHARP' VISUAL PATTERNS

I HAVE described[1] an after-image method demonstrating several features of the involuntary micro-ocular movements during the fixation of a test point (Fig. 1). If the eyes look steadily for some tens of seconds at the black point, and be then directed at the white point, the dark negative after-image of the white line pattern will be seen moving about irregularly.

In order to give inexperienced observers some idea of the after-image pattern to be paid attention to, a figure was constructed representing the sharp pattern together with the unsharp 'after-image' (Fig. 2). Surprisingly, the unsharp pattern appeared to move about irregularly, whereas the sharp pattern remained at rest. The sensation is evoked immediately on glancing over the pattern without previous fixation or a latency time permitting the production of clear after-images. The fact that the sharp image is white and the unsharp dark on a dark background is not essential because the illusion of relative movement is the same when, for example, both are dark on a white background. It seems clear that the apparent movements of the unsharp pattern are in some way the result of the micro-ocular movements, since these apparent movements are not unlike those of the after-image referred to here.

There are two questions to be answered. First, what information evokes the illusion of movement of the two patterns relatively to each other? Secondly, what determines which of the two patterns are seen moving, and which stationary?

It would seem that the phenomenon reported here is in some way related to that described by MacKay[2]: in a room lit stroboscopically at rates of 5–6/sec, self-luminous objects such as the glowing cathodes of thermionic valves appeared to move on pressing the eyeball with the finger, whereas the room remained relatively stable. When the retinal images of the sharp–unsharp pattern (Fig. 2) are displaced by a similar procedure the unsharp pattern seems to move with a larger amplitude. When the pattern is moved with respect to the observer—either from the left to the right, or up and down, or to and fro—the movements of the unsharp pattern are overestimated with respect to those of the sharp pattern. When the eye is moved smoothly over the pattern, for example, by following a moving fixation target (point of pencil), the sharp pattern seems to move with the pencil or the unsharp pattern seems to move in the opposite direction.

MacKay concluded from his observations that the magnitude of perceived movement is not primarily determined by the magnitude of displacement of the retinal image but by the amount of information supplied by the retinal image.

There is, indeed, some suggestive evidence from microelectrode studies of the vertebrate visual pathway—from the retina up to striate cortex—indicating that information about movement is not necessarily derived from information about locality. It seems, on the contrary, that the signals coming from the retinal receptor cells are combined and analysed by interconnexions between cells in the visual pathway in such a manner that the higher the centre the more quantitatively and qualitatively detached aspects of the original stimulus, for example, movement, becomes available[3–11].

The observations reported in this communication seem capable of interpretation along similar lines of reasoning. The different sensations of movement evoked by identical movements of sharp and unsharp retinal boundaries could arise from the larger number of movement receptor units being stimulated per unit of time and per unit of length in the stimulus gradient produced by the unsharp boundary as compared with the sharp boundary. Moreover, a given movement receptor unit might be stimulated during a longer period during the passage of the gradient produced by the unsharp boundary. The resulting differences in amount of movement information would evoke the sensation of relative movement of the sharp and unsharp boundary.

In general, the retinal pattern producing the greatest amount of movement information seems to evoke the strongest sensation of movement. In the ultimate decision about movement or rest of the objects belonging to retinal stimulus patterns two other sources of information are the motor innervation pattern of the extraocular muscles ('outflow-theory' of eye position knowledge) and the extension of the retinal stimulus patterns within the total visual field. Since there is ample evidence that proprioception in the extraocular muscles ('inflow-theory') gives no appreciable information concerning the position of the eyes[12–14], this source of information is left out of consideration.

When saccadic eye movements (visual grasp reflex) or smooth tracking movements are performed, the movements of the retina are reckoned with to some degree, with the motor innervation pattern of the extraocular muscles as information source, in deciding whether moving or stationary retinal images belong to stationary or moving objects. This results, for example, in the sensation of movement of an after-image object as soon as a voluntary eye movement is made (reafference principle[15]; cf. refs. 16 and 17). (In these considerations the sensational object is distinguished by the term 'image object' or 'after-image object' from its retinal image or after image.) Apart from, and sometimes in contradiction to, this information, there is the tendency to decide that smaller retinal patterns belong to moving objects, and that larger patterns belong to stable objects. This leads to visual illusions like the Moon 'moving' behind the 'stationary' clouds.

It is not clear to what degree the changes in the motor innervation pattern underlying the micro-ocular movements are used as a source of information in the interpretation of retinal movement information. Anyhow, an after-image, for example, of Fig. 1, does not move in a drift- and flick-like manner in complete darkness. Accordingly, the relative extension of the retinal stimulus patterns proves to have a strong effect on the sensations produced by the micro-ocular movements. A small, stable

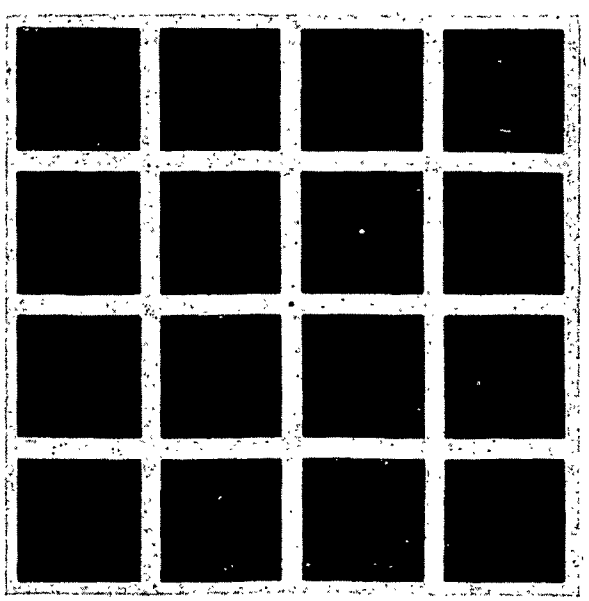

Fig. 1

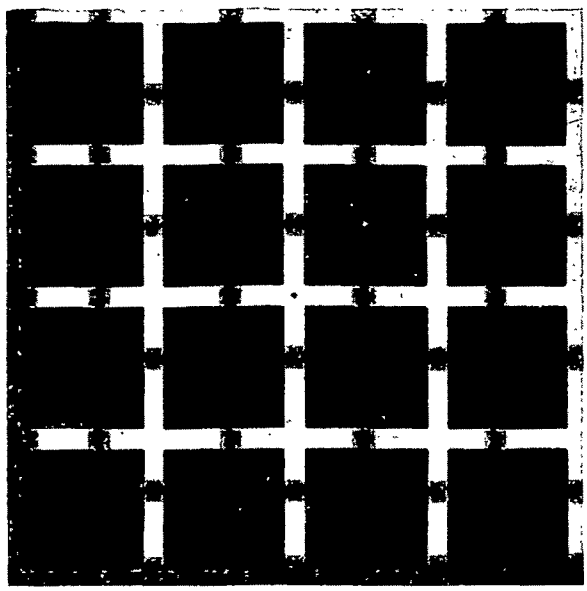

Fig. 2

light source fixed in complete darkness after the production (by electronic flash) of an after-image occupying a large part of the visual field, for example, of a pattern like Fig. 1, is generally reported to be in constant vibratory motion while the after-image object seems to be at rest. Similarly, the relative extension of the visual patterns can easily reverse the sensation of movement based on retinal information: when the unsharp part of a pattern like that in Fig. 2 is extensive and the sharp part small, for example, only one crossing-point, observers generally report that the sharp crossing-point vibrates with respect to the stationary unsharp pattern.

It seems that this illusion has something to do with Exner's *Punktschwanken* (point wobbling)[18] or that it is even identical with it. Exner distinguished between the continuous and smooth apparent movement of a spot of light in complete darkness, first described by Charpentier[19] and termed *autokinetische Empfindung* (autokinesia) by Aubert[20], and the apparent wobbling movements of a spot of light within a larger surrounding grey spot viewed in dim light. Hörwall[21] criticized Exner's idea that point wobbling would underlie the autokinetic illusion. Hörwall emphasized that point wobbling is only observed as an apparent irregular movement of small amplitude performed by the fixation point with respect to vague contours in its near environment, and that sharp contours inhibit the illusion. He ascribed the point wobbling illusion to the differences in latency time in localizing the retinal images of the vague contours and the sharp fixation point, both moving identically over the retina as a result of the involuntary movements of the eyes during fixation. It seems reasonable to suppose that differences in retinal movement information from the vague contour and the sharp fixation point, together with the different extension of both patterns, can account for Exner's *Punktschwanken*.

The essence of Dr. Verheijen's pleasing demonstration is that a blurred and a sharp contour, moving objectively with the same velocity over the retina, do not appear to move together. This could be caused by either: (*a*) a difference in the latency, or (*b*) a difference in the magnitude of the respective responses evoked in the visual system (or, of course, by both).

As a test of the first hypothesis, we have subjected sharp and blurred contours, successively and simultaneously, to oscillatory motion by reflexion in two mechanically rocked mirrors. If a signalling time-lag alone were responsible for the illusion, the estimated amplitude of movement should be the same for either image alone. In fact, it appears greater for the blurred contour, particularly if no stationary objects are present in the field to give cues to position, as distinct from amplitude.

By adjusting the relative phase of the two mirrors, it is possible to bring the blurred and sharp images approximately into step. The amplitude of 'motion' of the blurred image can then be seen to be the greater. If a signalling time-lag were responsible for the phase-difference, the phase setting required should vary with frequency of rocking. In fact, however, the 'phase lead' of the blurred over the sharp image is found to be practically independent of frequency.

We are thus driven to hypothesis (*b*), favoured by Dr. Verheijen, that more 'velocity information' is generated by the blurred contour; but since mere blurring, as distinct from mottling, does not increase the number of contours in motion, and since it diminishes the gradient of intensity, it is not easy to see why a greater number of 'movement detector units' should be stimulated.

A simple but striking experiment suggests that the spurious information here is generated in the detectors of intensity, rather than of motion. If the image of an 'optical wedge', projected on a screen, is displaced in the darker or lighter direction, the graded region appears lighter or darker respectively, so that the apparent displacement greatly exceeds the actual. Conversely, an increase or decrease in overall illumination gives rise to an impression of displacement in the darker or lighter direction, respectively.

Both phenomena invite a simple explanation in terms of local adaptation to intensity. If the graded image is displaced in the darker or lighter direction, then each intensity-detector finds itself under- or over-adapted, respectively, and the effect of this maladaptation is to enhance the change in response (by 'successive contrast')—as if the actual image-displacement had been greater. The effect is to make the perceived image 'lead' the actual (in space). Conversely, an overall change in illumination causes changes in response and in adaptation-level locally indistinguishable from those due to displacement of the graded image.

Our suggestion would therefore be that it is not the greater number of 'movement detectors' stimulated, but the spurious enhancement of the cues supplied to the movement detecting system, that accounts for the greater mobility of a blurred image.

PHYSICS

Continued X-ray Microanalysis of Radioactive Fall-out Particles during the Year 1962

Since the beginning of atom bomb tests, the physical and chemical properties as well as the biological effects of radioactive fall-out particles have been the subject of numerous investigations[1–8]. Discussions on the mechanism of formation of these particles and on the question of their effects on the human organism after inhalation or ingestion[1,2,4], which are highly dependent on their solubility, require a knowledge of their composition[1,4,9]. Comparison of particle diameters, obtained by electron microscopy, with the content of radioactive nuclides, determined by radiochemical methods and γ-spectrometry, shows that the particles contain more inactive material than is produced by the decay of the radioactive fission products and the induced radioactive elements[2,9]. In the case of atmospheric explosions, this additional inactive component comes from unfissionable materials used in building the atomic device, and in the case of near-surface explosions also materials from the ground can be involved[1].

During an investigation into the problem of radioactive fall-out particles in the winter of 1961–62[2], we tried to obtain information on the elemental composition of a radioactive particle[9] using an X-ray microanalytical method with the aid of the electron microscope[10]. This method consists essentially of focusing the electron beam of the microscope (Elmiskop I, Siemens) on the specimen, and using the characteristic X-ray spectrum to give the elemental composition. The X-ray spectrum, which is due mainly to the $K\alpha_1$-quantum energy, is absorbed in a proportional counter and then conducted to an impulse spectroscope where it appears as a pulse-height spectrum. In the spectra taken at that time, peaks appeared at 6·4 keV and 1·5 keV. Whereas the first peak belongs to the element iron ($K\alpha_1$-quantum energy 6·4 keV), the identification of the second peak was difficult as the $K\alpha_1$ energies of the elements aluminium (1·48 keV) and silicon (1·74 keV) are only slightly different. Afterwards it was possible to attribute this peak to the element aluminium having compared them with a calibration peak obtained by focusing the electron beam on an aluminium specimen.

In view of this result, we continued to use X-ray microanalysis in our work on radioactive particles collected in 1962[11].

Ten radioactive fall-out particles were, according to a method already published[2], prepared on electron microscope grids, located by autoradiography and later analysed by electron microscopy. With a mean maximum diameter of 4·4μ, the particles had β-activities of $3 \times 10^{-10} - 1 \times 10^{-8}$ curies (Table 1). To decrease the amount of scattered radiation in the microanalysis of the particles, a beryllium window was interposed. For all nine particles analysed there were peaks at 6·4 keV and the corresponding escape peaks at 3·5 keV representing the element iron (Fig. 1). In a second series of experiments the beryllium window was replaced by a thin mylar foil in order to allow analysis of the low-energy part of the spectrum. With this arrangement, the amount of scattering is higher and resolution of the peaks is correspondingly more difficult. The analysis of two of the seven particles examined indicated the existence of the element aluminium with a high degree of probability; the identification of the peaks at 1·5 keV was made possible by comparison with an aluminium calibration peak (Fig. 2). Four particles probably also contained aluminium. This result, however, could not be verified beyond doubt because of the high

amount of scattered radiation. One particle obviously contained no aluminium. The determination of the ratio aluminium: iron in the particles contains a relatively high error; it may, however, be said that the content of both elements seemed to be of the same order of magnitude.

The results obtained permit the assumption that the elements iron and aluminium frequently appear as inactive components of radioactive fall-out particles. Both elements probably come from materials used in the construction of the atomic weapons tested[8]. Thus, for example, radioactive fall-out particles consisting mainly of Fe_3O_4 have been described, in which the characteristic fission products are homogeneously distributed[8]. The outlines of the particles which we determined by electron microscopy fit the theoretically spherical shape of the particles of Fe_3O_4 mentioned relatively well; on the other hand, we also observed crystalloid shapes in many cases[2]. From the presence of iron in the radioactive particles, and thus also in the region of the fireball, it can also be deduced that during the explosion the iron must be activated to a certain degree. In fact the presence of iron-59 has recently been demonstrated in a preparation of air filter samples, using γ-spectrometry[12]. The spectra were recorded with the permission of Dr. H. Neff and with the help of Miss Schmiedeskamp and Mr. Hellgart at the Siemens Werk für Messtechnik, Karlsruhe.

This publication is dedicated to Prof. Boris Rajewsky on the occasion of his seventieth birthday on July 19.

Chemically Reduced Nickel Substrates for the Development of Uniaxial Anisotropy in Electro-deposited Thin Films

THE substrate surface characteristics are known to affect the hysteresis properties, the reproducibility, and the development of a uniaxial anisotropy in vacuum or electro-deposited permalloy thin (< 2000 Å) films. The primary requisites of a satisfactory substrate for development of uniaxial anisotropy in magnetic thin films are: (1) extreme smoothness; and (2) an amorphous or microcrystalline structure. Electroless nickel (chemical deposition) has been reported to be amorphous[1] as well as microcrystalline[2] in character. Consequently, chemically (electroless) deposited films of nickel were evaluated as substrates for electro-deposited permalloy films. The electroless nickel was deposited in a manner suggested by Brenner[3] on to a polyester film base.

The iron–nickel permalloy deposits were obtained from an electrolyte similar to that given by Wolf[4]. The current density was 6 m.amp/cm². The electrolyte was not agitated and was used at room temperature (27° C). All films were deposited in the presence of a magnetic field of 100 œrsteds. The composition of all deposits was approximately 81 per cent nickel–19 per cent iron. The films lacked any appreciable strain sensitivity in the easy and hard directions. The cathode diameter was 1·37 cm and the thickness of the deposits was varied from 500 to 2500 Å. This large ratio of spot diameter to thickness minimizes the magnitude of the demagnetizing fields in the plane of the film. The thickness was determined from the known geometry and the theoretical flux density.

The hysteresis parameters measured with a 60-cycle hysteresis loop tracer were: (1) the coercive force in the easy direction, H_c; (2) the anisotropy field, H_k; and (3) the maximum dispersion, αm, and quartile dispersion, αq. The dispersion was measured in the manner suggested by Crowther[5]. The hysteresis properties were examined as a function of substrate thickness and deposit thickness.

The maximum dispersion of the easy axis was found to be dependent on the thickness of the electroless nickel substrate and varied from 4° to 20°. This variation in dispersion with substrate thickness could be attributed to a substrate crystal growth irregularity or roughness. These irregularities in the substrate are replicated by the permalloy electro-deposit, resulting in a protruding grain growth and subsequent inhomogeneous composition of the permalloy deposit due to variation in the local cathode potential. The deposit non-uniformity has been characterized by determining the protruding grain-density per unit area from electron micrograph replicas of the surface at a magnification of 17,000. The correlation of maximum dispersion with deposit grain-density has been reported[6].

The results reported here show that an optimum thickness (time-temperature) of the electroless nickel substrate exists for minimum dispersion of the easy axis. Typical hysteresis loops of several permalloy deposits of various thicknesses on the optimum substrate thickness are shown in Fig. 1. The maximum dispersion was 5° and the quartile dispersion for all deposits was less than 1·5°. The hysteresis characteristics in the hard direction are shown

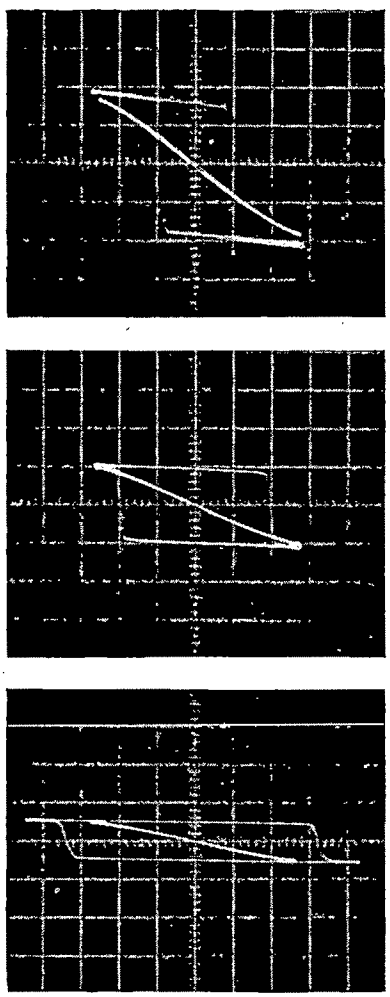

Fig. 1. Typical hysteresis characteristics of electro-deposited thin films on electroless nickel substrates *A*, 2000 Å, H_c = 0·9 œ, H_k = 2·8 œ; *B*, 1000 Å, H_c = 2·0 œ, H_k = 2·8 œ; *C* 500 Å, H_c = 3·3 œ, H_k = 3·0 œ. Maximum dispersion (α_{max}), 5°

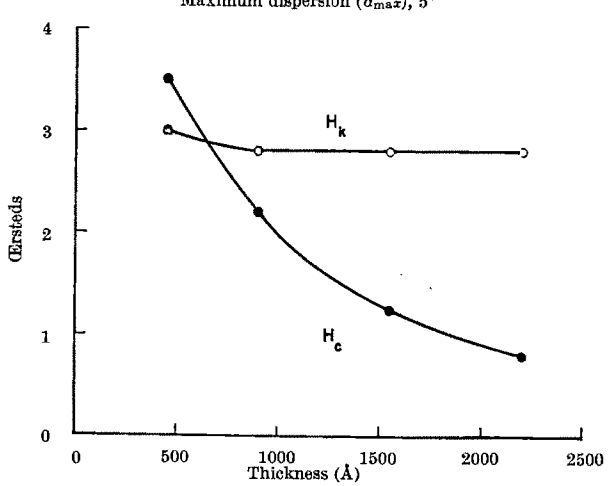

Fig. 2. Coercive force and anisotropy field of electro-deposited films as a function of thickness

to be nearly linear, indicating a high degree of coherent rotation of the magnetization or uniaxial anisotropy.

The coercive force of the deposits was inversely proportional to the thickness and varied from 0·9 œrsted at 2000 Å to 3·3 œrsteds at 500 Å (Fig. 2). The anisotropy field was nearly constant with thickness but varied slightly from 2·8 œrsteds at 2000 Å to 3·0 œrsteds at 500 Å (Fig. 2). The films were inverted, that is, the anisotropy field was less than the coercive force field, at thickness less than 700 Å. A plot of the logarithm of the coercive force versus logarithm of the thickness was linear and the slope was $-0{\cdot}45$. Thus, the coercive force may be expressed as an inverse function of the thickness to the 0·45 power. The value of 0·45 for the exponent of the thickness is considerably less than that previously reported by Lloyd and Smith for electro-deposited permalloy films[7]. The maximum dispersion is constant with decreasing thickness (500–2000 Å) in contrast to: (1) vacuum-deposited iron–nickel–cobalt films which have been reported to show an increase in dispersion with thickness below approximately 1500 Å (ref. 8); (2) vacuum-deposited iron–nickel films which show an increase in dispersion with increasing thickness (200–2000 Å) (ref. 9).

Measurement of Thermal Accommodation of Gases on Heated Solids

The usual method of measuring the thermal accommodation coefficient (α)—defined as the ratio of the average energy acquired by a gas molecule rebounding from the solid to the maximum which it could acquire after prolonged contact—has several limitations:

(*a*) α is deduced from the measured increment in loss of energy from a heated wire *in vacuo* when a small pressure of gas is introduced. Because of the strong dependence of radiation on temperature this increment becomes an increasingly small fraction of the radiation loss *in vacuo* as the temperature is raised, for example, for tungsten at 2,700° K in helium at 10^{-3} torr the fraction is about 10^{-3}, even if α be unity.

(*b*) The hot filament is electrically heated and is used as its own resistance thermometer, so the method is not applicable to insulating solids.

(*c*) The energy is carried by the gas from the hot wire by both translational and internal degrees of freedom. So for poly-atomic molecules it is necessary to know the specific heat in order to calculate α, and the result is an average of the degree of excitation of the translational and internal modes.

Our method depends on measuring, by means of a torsion balance (sensitivity $\sim 7{\cdot}5 \times 10^{-2}$ dyne cm radian^{-1}), the mean momentum, and hence velocity, of molecules rebounding from a hot solid immersed in a rarefied gas at temperature T_0. It therefore measures directly the effective translational temperature (say T) of molecules leaving a heated solid of temperature T_1.

$$\text{Thus } \alpha = \frac{T - T_0}{T_1 - T_0}$$

The method becomes more sensitive the higher the temperature, is not confined to metals, is concerned only

with translational accommodation, and does not involve any assumptions about specific heat.

Since the deflexion of the balance depends on the impact momentum and the degree of its reversal at the balance arm, an assumption about the momentum accommodation coefficient of the latter must be made. It must lie between zero and unity, and results have been calculated on both assumptions, though the latter is much more likely, as the surface of the balance arm has not been specially cleaned.

Preliminary experiments on a tungsten wire in helium, argon and nitrogen at pressures of order 10^{-3} torr give the following values of α at 2,800° K—a temperature at which the surface of the tungsten is likely to be clean—helium, 0·07–0·12; argon, 0·23–0·50; nitrogen, 0·35–0·72, the range of values resulting from the two extreme assumptions mentioned here.

The experiments have been performed with the tungsten wire in a fixed position relative to a carefully designed system of apertures, so that only molecules coming from an isothermal and geometrically defined part of the tungsten wire can reach the balance arm directly.

Future experiments are being designed so that the heated body (for example, tungsten) can be replaced at will by the aperture of a furnace from which the issuing molecules can be assumed to be in thermal equilibrium. The degree of momentum accommodation on the balance arm can then be directly determined, made to approach unity by suitable surface treatment, and the foregoing ambiguities removed.

Phonon Concept at High Temperatures

To deduce an expression for the lattice thermal conductivity it is usual to consider the volume of the solid as occupied by a 'phonon gas', and then to find the resistivities due to the scattering of the phonons by other phonons, electrons and structural defects[1].

Such theories assume that the phonons behave like particles, except that their number is not conserved. However, each phonon is really a group of waves. At high temperatures, defined by $\omega\tau < 1$, where ω is the angular frequency and τ the lifetime of the interacting phonon, only part of this wave train may be affected by a collision. Thus the phonon-quasi particle duality sometimes becomes invalid at high temperatures.

This is corroborated by experimental evidence[2]: a group at the Massachusetts Institute of Technology recently found that the thermal conductivity of solid solutions of $Mg_2Pb_xSn_{1-x}$ for $0 \leqslant x \leqslant 30$ per cent at room temperature did not follow the functional form suggested by Klemens's[3] equation. It becomes necessary to rely on phenomenological theories[4] to relate thermal conductivity data at high and low temperatures[5,6]. The term 'phonon' at high temperatures is frequently found in the literature when it would be better to speak of lattice waves[7,8]. Thus the limits of application of the phonon concept need further investigation.

GEOLOGY

Velocity of Sliding of an Ice-fall

During the Nepal Himalaya *P*-29 (7,835 m) Expedition of Osaka University Mountaineering Club, 1961, we had some experience on sliding and avalanches of an active ice-fall; analysing photographs taken by a Canon 2,000 mm telephotographic lens from the base camp at 4,400 m high. Fig. 1 is a series of photographs taken at: (*a*) May 10, 1° 30′ p.m.; (*b*) May 11, 9° 30′ a.m.; (*c*) the same day 11° 30′ just after a small avalanche. By comparing the photographs (*a*) and (*b*) we can see that the glacier ice slid down as shown in Fig. 2. The distance of sliding on the original photograph was 2·0 mm. As the distance from the base camp to the ice-fall was 4 km, it corresponds to 4 m. As the estimated slope was 60°, the speed of sliding of the ice-fall became 6 m/day. Evidently this value is too large compared with the usual

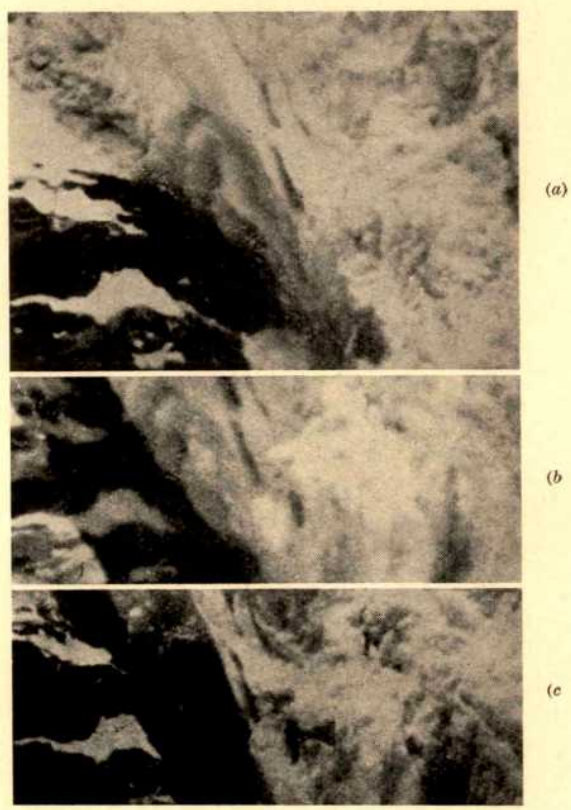

Fig. 1

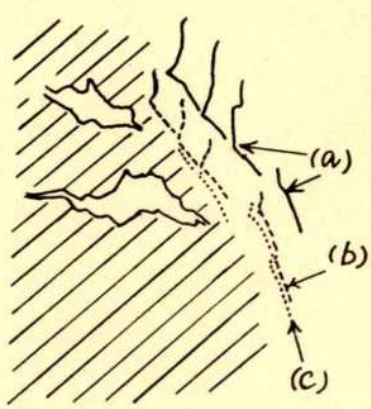

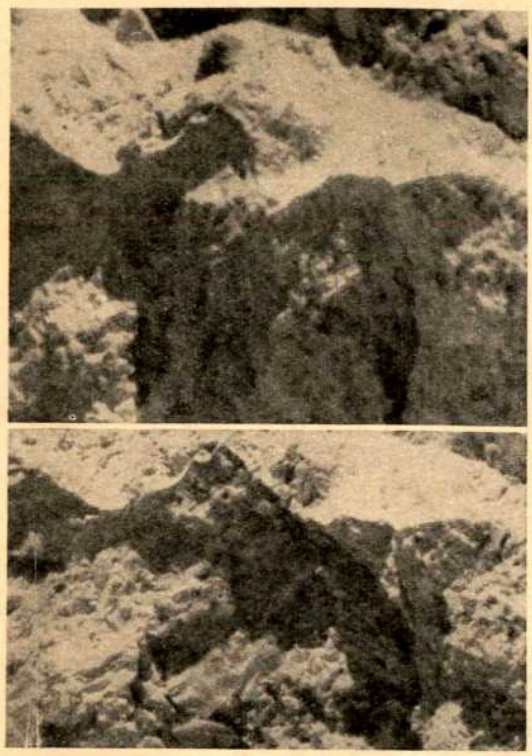

Fig. 2

(b′)

(c′)

Fig. 3

velocity of flow of a glacier. But as an avalanche occurred immediately afterwards, this value may not be unreasonable and gives some information on mobility of an ice-fall during the pre-avalanche period.

If we compare the photographs (*b′*) and (*c′*) of Fig. 3 which are on the right-hand side of (*b*) and (*c*) respectively, we can see the changes in the shape of a part of the cornice, that is, an overhanging rectangular block of ice has disappeared after the avalanche. As its volume was $8 \times 8 \times 40 \simeq 2{,}600$ m^3, if we take specific gravity of ice as 0·75, its weight was about 2,000 tons. Obviously this avalanche was quite a small one.

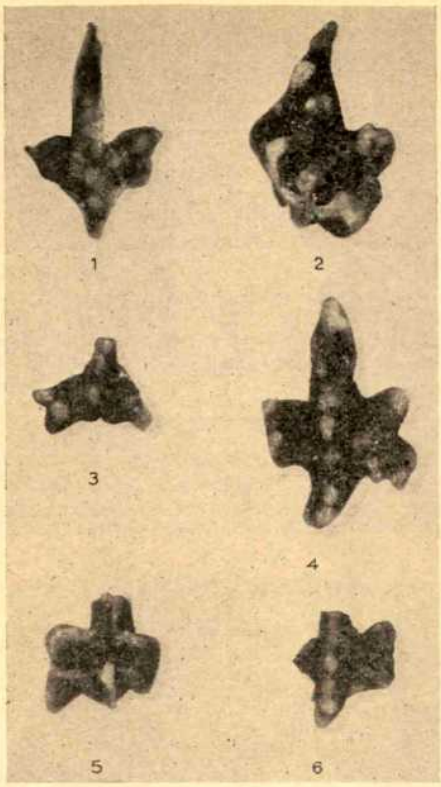
Occurrence of *Kockelella variabilis* Walliser in the Aymestry Limestone of Shropshire

A collection of 1,400 conodonts collected by one of us (G. N.) in the course of a regional study of the Upper Silurian of Shropshire was submitted to the other (F. H. T. R.) for identification. Among these were found twelve fragmentary specimens not included in the fauna described by Rhodes[1] from the Aymestry Limestone. These represent *Kockelella variabilis* Walliser, originally recorded from the Silurian of Germany (from the Rheinisches Schiefergebirge, basal Orthocerenkalkes of Frankenwald and the *Cardiola* Horizon of the Karnische Alps[2]). The genus has also been reported from the Province of Malaga in Spain[3], the Lower Ludlovian of the Regganne area of southern Algeria[4] and the Silurian of the Tindorf Basin of the Spanish Sahara[5]. Ziegler[6] considered the species a good index for rocks of Middle Ludlovian age, but Walliser[7] showed it as characteristic of the Lower Ludlow. It therefore seems useful to record and illustrate the occurrence of the present specimens, which suggest an extension of the known range of the genus, even though the specimens are too fragmentary to provide any new morphological information.



Genus *Kockelella*. Type species *Kockelella variabilis* Walliser[2]. The genus *Kockelella* has a broad resemblance to *Amorphognathus* but is distinguished by the form of the basal cavity. In *Kockelella* this consists of an anterior slit-like excavation which is expanded at about the mid-length into a wide, flaring cavity, with a subcircular outline. The lateral 'branches' which are conspicuous in the oral view are developed only on the oral surface of what is essentially a platform formed by the flaring aboral cavity, and they are quite unrepresented in aboral view. This supports Walliser's contention[2] that *Kockelella* is closely related to, and presumably derived from, *Spathognathodus*. The only substantial difference between the two genera is the development of lines of lateral denticles on what would correspond to the oral surface of the expanded 'pulp cavity' in *Spathognathodus*. Present usage of that genus includes forms with such denticulation, however. Thus Hass[8], describing *Spathognathodus*, writes "oral surface of lips or lateral expansions of pulp cavity may support denticles". The genus is, in fact, one of the most variable of all conodont genera and, in spite of Walliser's careful discussion of his reasons for distinguishing *Kockelella* from it, it is still possible that the two are synonymous. The present specimens are too few and too fragmentary, however, to provide any basis for a firm opinion.

Kockelella variabilis Walliser (Figs. 1–6); *Kockelella variabilis* Walliser[2]; *Kockelella variabilis* Ethington and Furnish[5]. The present specimens, although fragmentary, are very similar in their general form to those illustrated by Walliser.

The main denticulated blade is incomplete on all the present specimens, but on one of them (Fig. 4) the posterior blade is gently flexed in a horizontal plane, showing a close resemblance in this to some of Walliser's figured specimens (for example, ref. 2, Pl. 1, Figs. 6–10). The oral platforms of the Aymestry specimens are also poorly preserved but some specimens (for example, Figs. 2 and 4) show the presence of two well-defined rows of denticles on one side of the platform, and these appear very closely similar to those in Walliser's illustrations. Other specimens show only one row of denticles on the oral surface of the platform but in none of the Aymestry specimens are both sides of the oral surface of the platform sufficiently well preserved to determine the general character of the denticulation. One incomplete specimen suggests the presence of one row of denticles on one side and two on the other side of the platform, and another (Fig. 4) of two rows on each side. Such variation also exists within Walliser's specimens, and is regarded as infraspecific.

The form of the basal cavity (Fig. 5) in the present specimens is in all respects similar to that described by Walliser. The most striking features of this cavity are its relatively thick 'lips', its slit-like character below the median blade and its broad extension below the oral platform. This extension tends to be laterally oval and is conspicuously smaller than the oral extension, the blunted terminal teeth of which project outwards from it in basal view. It has a (very) broad resemblance to the basal view of a padded coronet, with blunted uprights projecting upwards and outwards from the circlet.

The present specimens were collected in a disused quarry at Shelderton, Shropshire (National Grid Reference: 32/418778), about 2½ miles north-north-east of Leintwardine, from a horizon some 40 ft. above the base of the quarry. The Aymestry Limestone here is equivalent to the Upper Bringewood Beds of the revised Ludlovian classification[9]. Conodonts are abundant at this horizon[1] though *Kockelella variabilis* is rare, the 12 specimens being part of a collection of more than 1,400 conodonts. The limestone is nodular and contains at this horizon a pre-

Figs. 1–6. *Kockelella variabilis* Walliser. Figs. 1–4 and 6. Oral views of specimens Nos. *C*-1–19, 16, 41, 15, 39; Fig. 5. Aboral view of specimen No. *C*-1–27. (× *c.* 20.) Catalogue Nos. refer to specimens in the Department of Geology, University of Manchester

dominantly brachiopod fauna, *Atrypa reticularis* and *Strophonella euglypha* being especially common. Phosphatic calculi, too, are very abundant[10].

At another horizon in the same quarry at Shelderton (21 ft. from the base of the quarry) *K. variabilis* occurs in the highly siliceous rock, mentioned by Rhodes[1]. *Kockelella* has not been found, however, in the lower part of the limestone, where conodonts generally are less common. *Kockelella variabilis* has also been found among conodonts extracted from the Aymestry Limestone (Upper Bringewood Beds) at View Edge (National Grid Reference: 32/425806), where it is associated with *Conchidium knighti* in the massive shell bank.

Work is at present being carried out by one of us (G. N.) on the faunal and lithological associations of *Kockelella* and other conodonts.

CRYSTALLOGRAPHY

Doped Synthetic Diamonds—Anomalous X-ray Spikes Along <111>

Lonsdale and Smith[1] showed that type I natural diamonds give anomalous X-ray diffraction scattering along <100> directions in reciprocal space. Hoerni and Wooster[2] explained the intensities of this phenomenon in terms of impurity atoms in {100} planes, these impurity atoms having a scattering power not much different from that of carbon. Kaiser and Bond[3] published data, based on residual gas analyses, indicating that type I (infra-red opaque) diamonds (but not the transparent type II) contain up to 0·23 per cent of nitrogen-14, the amount being proportional to the intensity of the 7·8μ absorption band. They did not, however, attempt to correlate the quantity of nitrogen-14 present with the intensity (or indeed the presence) of X-ray extra spikes in the diamonds they used. Nor was this correlation made by Evans and Phaal[4], who obtained from type I (infra-red opaque) diamonds elegant transmission electron micrographs which show the presence of {100} impurity platelets, the impurity being assumed to be nitrogen.

So far we had observed no X-ray spikes in any synthetic diamond examined.

Through the kindness of Drs. R. H. Wentorf and H. M. Strong of the General Electric Co., Schenectady, we have now had the opportunity of examining very small synthetic diamonds which have been doped with boron, aluminium and nitrogen respectively, some during growth and some afterwards; and also natural diamonds doped with boron at high pressures.

All these do show X-ray spikes; but along <111> and not along <100>. Some of the diamonds are so badly distorted that the effect is a little doubtful; but it is particularly well shown by synthetic diamonds doped with aluminium during growth[5] (Fig. 1), iron being the metal 'catalyst' used to promote the diamond formation.

In Fig. 1 natural (type I, undoped) and synthetic (aluminium-doped) diamond Laue pictures are arranged in pairs. When the natural type I diamond is in such a position that the incident beam is nearly normal to (11$\bar{1}$), the 111 reflexions are accompanied by <100> spikes (cf. ref. 6). In a parallel position the doped synthetic diamonds show a configuration of spots in an isosceles triangle with a long (vertical) base. The reverse occurs for the alternative $\bar{1}\bar{1}\bar{1}$ setting, in which the natural diamond shows a triangular configuration of spots (but this time the triangle is more nearly equi-angular) and the doped synthetic diamonds show short streaks. Doped natural diamonds show the same effects as doped synthetic ones, and the geometry of these for copper K and cobalt K radiation proves that they lie along <111> directions, thus corresponding with concentrations of defects in {111} platelets.

Owing to the very small size of most synthetic diamonds and the considerable distortion found in these and in the doped natural diamonds examined which were also very small, no systematic attempt has yet been made to observe the relative [111] spike intensities for reflexions other than 111 or to correlate them with the type of impurity atom used for doping (cf. ref. 2). Attempts may be made to obtain electron micrographs for aluminium–iron synthetic diamonds, in order to find the distribution of the {111} platelets, which may well be on or near to the surface, since most diamonds have octahedral faces.

Some of the doped synthetic diamonds exhibit semiconducting properties. Among natural diamonds it is the rarer type II*b* which are semi-conducting[7] and these do not show any anomalous diffraction spikes.

Since aluminium-doped synthetic diamonds appear to give particularly good spikes it might seem curious that aluminium in natural diamonds does not seem to be concentrated in a similar way. Chesley[8] found the presence of

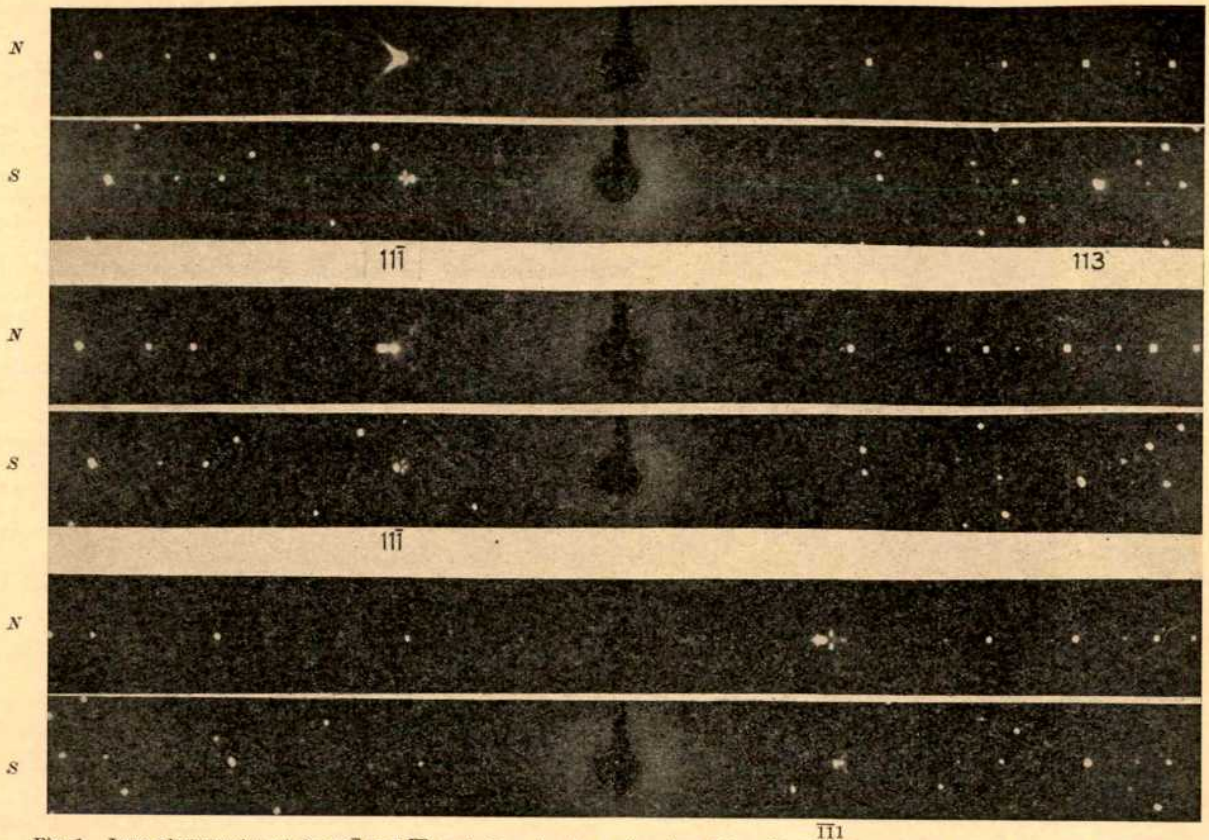

Fig. 1. Laue photographs set for 11$\bar{1}$ and $\bar{1}$11 reflexions showing spikes in <100> directions for natural type I diamond and <111> directions for aluminium-doped twinned synthetic diamond. *N*, Natural type I diamond; *S*, doped synthetic diamond

aluminium, together with silicon, calcium, magnesium, iron and other minor constituents, in many natural diamonds, but Raal[9] found no correlation between the absorption features and the concentration of these elements, which in no case exceeded 80 parts per million. Yet aluminium is abundantly present in Kimberlite minerals. This may indicate either that when natural diamond was formed most of the silicates had already crystallized, or that diamond was not formed in the silicate magma into which it afterwards migrated.

CHEMISTRY

Structure of Silyl and Methyl Azides and Isocyanates

Evidence has been presented that the heavy atom skeletons of silyl isocyanate[1] and isothiocyanate[2] are linear while those of silyl azide[1], methyl azide[3] and isocyanate[4] are non-linear. This communication offers an explanation for these differences.

The systems are all H_3AXYZ, where A is carbon or silicon, and XYZ is either NNN or NCO (or NCS). If A is silicon the valency shell of A can be expanded beyond the octet. The linear structures possible in this case are I to VI (ref. 5). It is reasonable to suppose that a nitrogen atom can satisfactorily assume formal charges between $+1$ and $-\frac{1}{2}$, because NH_4^+ is stable in ordinary circumstances but NH_2^- only under special conditions. If this is accepted, I, II, IV and VI would be unsatisfactory structures energetically for H_3SiNNN. With III, there is a formal charge of -2 on the silicon and a triple bond between Si and N. It is therefore unlikely to be of low energy. With V there is a formal charge of $-1\frac{1}{2}$ on the silicon and a $2\frac{1}{2}$: bond between Si and N. It is also unlikely to be of low energy. Therefore there is no satisfactory linear structure for H_3SiNNN. On the other hand, I and II, and particularly IV and VI (ref. 5), are satisfactory for H_3SiNCO; with Z = oxygen, the formal charges on Z are 0, -1, $-\frac{1}{2}$ and 0 for I, II, IV and VI. The existence of H_3O^+ and OH^- shows that an oxygen atom can assume formal charges between $+1$ and -1 in stable species. In addition, the replacement of nitrogen at Y by carbon changes the formal charge at that atom from $+1$ in the azide to zero in the isocyanate, increasing further the stability.

In methyl isocyanate, the valence shell of A is restricted to an octet, and therefore, of the above six linear structures, II only is allowed. On the other hand, VII and VIII, which would be non-linear, are even more satisfactory, because the formal charges on the atoms A, X, Y, Z are respectively 0, 0, 0, 0 and 0, $-\frac{1}{2}$, 0, $+\frac{1}{2}$. In all these structures (II, VII and VIII), the number of electrons in the $AXYZ$ system is ten. Consequently, methyl isocyanate would be expected to be a hybrid of bonding VII and VIII, and bent. For methyl azide, II is impossible energetically because of a formal charge of -2 on Z; VII is most unlikely because of a formal charge of -1 on Z; on the other hand, VIII is satisfactory because the formal charges in the $AXYZ$ system are 0, $-\frac{1}{2}$, $+1$, $-\frac{1}{2}$; all these are allowable. Hence methyl azide will

be bent. In addition to VIII, because the valence-shell of silicon can be expanded beyond eight electrons, silyl azide can have the structure IX in which the formal charges on A, X, Y and Z are $-\frac{1}{2}$, 0, $+1$ and $-\frac{1}{2}$. In IX there are a greater number of electrons in bonds than in VIII so the former is probably preferred. However, both correspond to non-linear structures so silyl azide will be expected to be bent. Structures I to VI have been shown to be unsatisfactory, and VII is unsatisfactory for the same reason as for methyl azide.

$H_3A{=}X{=}Y{=}Z{=}$ I $\quad$ $H_3A{\overset{x}{=}}X{\overset{o}{-}}Y{\overset{x}{=}}Z{\overset{o}{-}}$ V

$H_3A{-}X{\equiv}Y{-}Z{\equiv}$ II $\quad$ $H_3A{\overset{x}{\underset{x}{-}}}X{\overset{o}{\underset{o}{-}}}Y{\overset{x}{\underset{x}{-}}}Z{\overset{o}{\underset{o}{-}}}$ VI

$H_3A{\equiv}X{-}Y{\equiv}Z{-}$ III $\quad$ $H_3A{-}\overset{|}{X}{=}Y{=}Z{=}$ VII

$H_3A{\overset{x}{-}}X{\overset{o}{=}}Y{\overset{x}{-}}Z{\overset{o}{=}}$ IV $\quad$ $H_3A{-}\overset{x}{\underset{|}{X}}{\overset{o}{-}}Y{\overset{x}{=}}Z{\overset{o}{-}}$ VIII

$H_3A{\overset{x}{-}}\overset{x}{\underset{|}{X}}{\overset{o}{-}}Y{\overset{x}{=}}Z{\overset{o}{-}}$ IX

The essential reason why silyl isocyanate and isothiocyanate are linear is that the multiple (or π) bonding in the SiN bond and the resulting electron distribution can be accommodated when the end atom is oxygen (or sulphur). They cannot be accommodated in silyl azide in which the end atom is nitrogen, because of its lower nuclear charge. Consequently the nature of the atom at one end of the chain affects the double (or π) bonding at the other.

Constant Energy Differences in Atomic Structure

In a recent article Dash[1] has emphasized how three successive ionization potentials I_p, I_{p+1}, I_{p+2} in an isoelectronic series of atoms give a constant second difference which is equal to twice the Rydberg constant R divided by the square of the principal quantum number n of the electron being ionized, thus:

$$I_p - 2I_{p+1} + I_{p+2} = 2R/n^2 \qquad (1)$$

This relationship is a mathematical consequence of Glockler's[2] empirical quadratic:

$$I = \frac{R}{n^2}[\alpha Z^2 + \beta Z + \gamma] \quad (Z \text{ is the atomic number}) \qquad (2)$$

if α, β, γ are constant in an isoelectronic series, and if $\alpha = 1$ as shown empirically by Lisitzin[3] some years ago.

Dash's article provides, therefore, further empirical support for this quadratic. The evidence for it has recently been reviewed by me, and a derivation given from elementary quantum-theory using screening constants which have other applications[4]. A wave-mechanical derivation has since been given by Crossley and Coulson[5]. Both derivations explain simply why α is unity.

Influence of Crystal Defects on the Annealing of Chemical Radiation Damage

Recent investigations have shown that crystal defects determine the fate of the fragments generated in solids by radiative thermal neutron capture as well as the kinetics of subsequent annealing reactions[1,2]. So far, there has been no experimental evidence for the influence of defects on the annealing of chemical damage produced in solids by irradiation. We have now obtained such evidence in the case of annealing in lead nitrate.

Previous workers had introduced defects by crushing, exposure to ionizing radiations, or by incorporating in the crystal small concentrations of ions bearing a different charge to the corresponding ions in the host lattice. It is known[3,4] that vacancies, and possibly interstitials, are generated in ionic solids also by compression. We compressed under 40 tons/in.^{2} crystals (30–100 mesh) of lead nitrate which had been previously dried and irradiated *in vacuo* in sealed 'Pyrex' ampoules with about 50 Mrads of cobalt-60 γ-rays. The compressed and the uncompressed samples were heated for different time intervals at 150° C. The experimental procedure for estimation of the damage was as reported earlier[5,6].

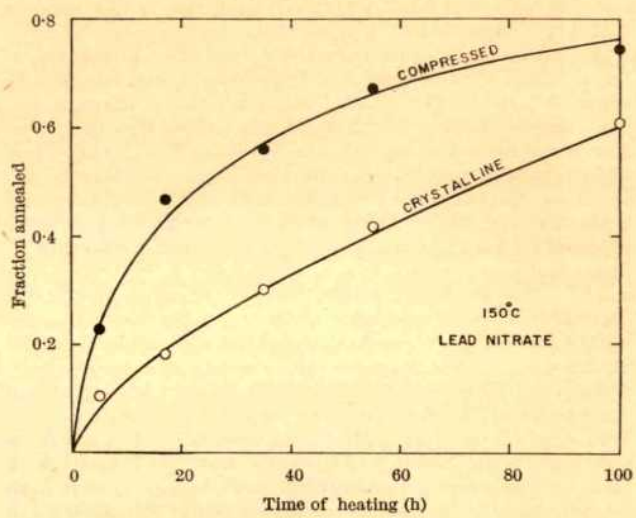

Fig. 1. Influence of compression on the annealing in lead nitrate

In Fig. 1 is shown the fraction of damage annealed against the time of heating in hours. The greater annealing of the compressed material as compared with that of the uncompressed crystals is evident. Thus, the fraction annealed over 35 h was 0·300 for the uncompressed, and 0·559 for the compressed, salt.

We thank Mr. Mata Saran for his help with the compression experiments. We also thank the Atomic Energy Establishment, Trombay, for the irradiations which were performed with the gamma-ray and sterilization unit presented by the Government of the United States. One of us (S. R. U.) gratefully acknowledges award of a scholarship by the Ministry of Scientific Research and Cultural Affairs, Government of India.

Determination of *n*-Alkanes in Mixtures of Saturated Hydrocarbons by Means of Gas Chromatography

Methods of using molecular sieves 5*A* in gas chromatography for removing *n*-alkanes have been described previously[1,2]. According to these methods, two tests have to be performed, and the results can only be calculated after correction for differences in the size of samples has been made by means of internal markers. Such a procedure sometimes requires samples larger than those available, for example, for rock-extract analysis.

We have avoided the need for a two-fold test by placing a normal gas-chromatographic column in series with the measuring channel of a heat-conductivity cell, a 10-cm column filled with Linde 5*A* molecular sieves (50/80 mesh) and the measuring channel of a second heat-conductivity cell. This arrangement gives us two chromatograms of a single injected sample, one with and one without the *n*-alkanes. Assuming that all the compounds in the mixture of saturated hydrocarbons have roughly the same heat conductivity, we can calculate the individual *n*-alkane percentage directly from a comparison of the chromatogram areas. These areas can be determined very simply, for example, by being cut out and weighed, provided that the paper used is suitably homogeneous.

An essential condition for the successful functioning of the method is, of course, that the sieves should completely retain all the *n*-alkanes and allow all the isoalkanes and cyclanes to pass. We have found that the activated sieves do indeed retain all the *n*-alkanes, but that they unfortunately also retain a portion of the isoalkanes and cyclanes. Experiments with a number of C_{16} isomers and 2-Me-eicosane showed that when very small samples were injected (< 1 mg) as much as 50 per cent might be retained. Since the percentage always decreased as the amount of sample increased, we came to the conclusion that a certain absolute quantity of isoalkanes is always adsorbed by the sieves. This adsorption can be suppressed to some extent—but not altogether—by coating the sieves with 2 per cent silicone fluid '*GE/SF*96'. Our findings are in agreement with those of Downing *et al.*[3]. Adlard and Whitham[4] state that 2-Me-eicosane is not adsorbed from the gas phase. Their experiments were performed with samples weighing several milligrams[5], however, and with samples as large as this we have not found the adsorption of C_{16} isomers to be noticeable either.

The equipment can be assembled from various types of commercial gas liquid chromatographic apparatus. The need for two well-matched gas liquid chromatographic detection units is inherent to the method, however. Since two heat-conductivity cells rarely have exactly the same sensitivity, it will usually be necessary to shunt the more sensitive cell electrically.

The method has proved useful for the determination of *n*-alkanes in the C_{10}–C_{20} range, where preconcentration is not needed. Above *n*-C_{20} preconcentration is required, urea adduction being one method of doing this.

Full details concerning the method and the results obtained with it are shortly to be published elsewhere[6].

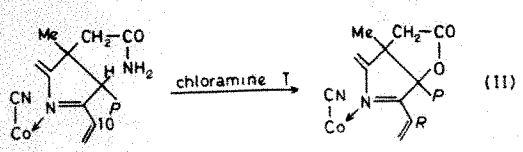
Sulphitocobalamin

A wide range of cobalamins exist where the cyano group of the original vitamin B_{12} is replaced, for example, by water (vitamin B_{12b}), halides, nitrite, sulphur-containing groups, and alkyl groups (the coenzymes and analogues) and the nature of the ligand attached to the cobalt has a profound influence on the chemical and physical properties of the cobalamin.

Preliminary experiments directed towards the synthesis of the vitamin B_{12} coenzyme[1] consisted of a re-investigation of the action of certain sulphur-containing reducing agents on hydroxocobalamin following the report of Pawelkiewicz[2], who claimed a synthesis of the coenzyme form of Factor *B* by the sodium dithionite reduction of cobinamide, Factor *B*, in the presence of adenine. We have repeated this experiment with hydroxocobalamin and failed to obtain any product which contained adenine linked to the cobalt. However, a new light-sensitive product was obtained from the reaction, the same product also being obtained in the absence of adenine. The reaction of sodium bisulphite with hydroxocobalamin also gave the same crystalline product, the spectrum of which was somewhat similar to that of vitamin B_{12} coenzyme[3]. Electrophoresis at *p*H 8 indicated that the compound contained an additional acidic group compared with vitamin B_{12} and that it was stable both in solution and in the solid state in the absence of light. The product contained sulphur and the presence of the monoacidic sulphite ligand was suggested by the electrophoretic behaviour and by the presence of two strong bands at 983 and 1,150 cm^{-1} in the infra-red spectrum; these bands have been associated with the cobalt-sulphur linked sulphito group by Baldwin[4] in another series of cobalt-containing complexes. On this basis the sulphito compound is formulated as in the partial structure (I), the remainder of the molecule being the normal cobalamin skeleton.

(I)

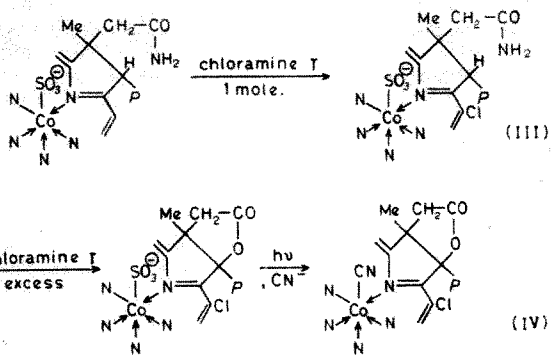


Sulphitocobalamin has been recorded in the earlier literature[5], but thought to exist only in solutions containing excess sulphite ions. More recently, Hill, Pratt and Williams[6] have described the properties of solutions of sulphitocobalamin and proposed a structure essentially similar to (I); both these workers and Bernhauer, Renz and Wagner[7] have described similar sulphito complexes from cobinamide (Factor *B*).

Like the coenzyme and its alkyl analogues[1,8], sulphitocobalamin readily reacts with acid (*p*H 2) to form a yellow protonated form (see ref. 6), but the acid solution is unstable and rapidly reverts to hydroxocobalamin. Cyanocobalamin (vitamin B_{12}) and hydroxocobalamin (vitamin B_{12b}) require treatment with strong mineral acid to yield the yellow protonated forms.

Aerobic photolysis of an aqueous solution of the sulphito complex gave hydroxocobalamin although under anaerobic conditions (10^{-6} mm) the complex was stable to photolysis. In this respect it resembled the simple alkyl analogues of the coenzyme[9] although the coenzyme itself undergoes fission when subjected to anaerobic photolysis[10]. Treatment of the sulphito complex with either potassium cyanide or hydrogen cyanide gives dicyanocobalamin. In this reaction the substitution at the cobalt atom occurs much easier, especially with potassium cyanide, than the similar reaction with the coenzyme and its alkyl analogues.

The course of the reaction of chloramine *T* with sulphitocobalamin also resembles the corresponding reactions with the coenzyme and the alkyl cobalamins, and differs in



certain respects from the reaction of chloramine *T* with cyano- and hydroxo-cobalamins. In an earlier communication[11] it was shown that the action of the first equivalent of chloramine *T* with cyano- or hydroxo-cobalamin yielded a lactone (II; *R* = H) fused to ring *B*; further reaction caused substitution probably at C(10) of the chromophore to give the chloro-lactone (II; *R* = Cl).

(II)

(P = $CH_2 \cdot CH_2 \cdot CONH_2$)

The reaction of the sulphito complex with one mole of chloramine *T* caused substitution without cyclization and the product was the 10(?)-monochloro derivative (III). Reaction with excess chloramine *T* caused the formation of a monochloro-lactone (III) of the sulphito compound revealed by the appearance of the characteristic lactone carbonyl band at 1,778 cm^{-1}. Photolysis of this chloro-lactone (IV) in presence of air caused the formation of the corresponding hydroxocobalamin derivative and this with cyanide gave the same chloro-lactone (II; *R* = Cl) as had been obtained previously[11] by treatment of cyano-cobalamin with excess chloramine *T*.

The course of the chlorination reaction is thus similar to that observed[9] with methylcobalamin, but the order of reaction at different points of the chromophore differs in the chlorination of cyano- and hydroxo-cobalamins.

Composition of Montan Wax

In a previous communication[1] we described the separation, identification and determination of the methyl esters of the long-chain fatty acids present in montan wax. This work was afterwards confirmed by Wollrab, Streibl and Sorm[2], who also used a flame ionization detector. They, however, used a chromatographic column containing 5 per cent 'Apiezon *L*' on ground tile and preconditioned by vacuum sublimation at temperatures of up to 350° C and operated at 335° C. These authors recorded the presence in montan wax of all the straight-chain normal fatty acids in the range C_{22}–C_{34} that we had previously identified, and in addition the C_{33} acid which we had not at that stage reported.

In further work we have used a 5-ft. length of column packed with polyethyleneglycol adipate and phosphoric acid[3] on 'Celite', fitted to a Pye 'Panchromatograph' with an argon ionization detector. This has enabled us to confirm the presence in montan wax of the C_{33} long-chain fatty acid, and also to detect a number of other fatty acids. We have also examined the hydrocarbon and alcohol fractions of montan wax, and confirmed the presence of long-chain carbon compounds.

For these separations an argon flow-rate of 37·5 ml./min was obtained with a supply pressure of 8 lb./in.^{2}. An anode potential of 1,000 V was used, and the column and detector were operated at 150° C for separation of the alcohol fraction and at 200° C for the hydrocarbon and fatty acid ester fraction.

The following summary of the composition of these three fractions of montan wax is based on a large number of separations of these materials, which were isolated as described by Tanner *et al.*[4] from the parent wax.

Hydrocarbon fraction. This fraction was found to be composed of straight-chain hydrocarbons, largely C_{23}–C_{33}, but with smaller amounts of C_{16}, C_{18} to C_{22}, C_{34} and C_{35}. These compounds were identified by the linear relation existing between log retention-time and carbon number. In addition to these straight-chain hydrocarbons, a second series of related compounds was also recorded, with a parallel log retention-time/carbon-number relation. These retention times did not correspond to those of unsaturated hydrocarbons, but are comparable with those expected for branch-chain hydrocarbons with carbon numbers similar to those of the straight-chain series observed.

An analysis of the hydrocarbon fraction, based on peak area measurements, is given in Table 1; the compounds are listed in order of elution, the straight-chain compounds being identified by carbon numbers. Compounds identified as present but not listed in Table 1 were present in trace amount only.

Table 1. Analysis of Hydrocarbon Fractions

Carbon No.	Wt. %	Carbon No.	Wt. %
C_{23}	2·3	C_{29}	10·3
C_{24}	3·7		1·6
	2·0	C_{30}	9·3
C_{25}	4·9		6·8
	0·9	C_{31}	7·1
C_{26}	7·4		1·3
	3·6	C_{32}	4·4
C_{27}	8·5		3·3
	1·9	C_{33}	3·1
C_{28}	10·4		1·0
	6·2		

Long-chain fatty acid fraction. All the normal straight-chain fatty acids in the range C_{16}–C_{35} were recorded as their methyl esters. An analysis reporting the major components of this fraction has already been published[1]: the additional compounds now identified as present occur in only trace amounts. In addition to the normal fatty acid esters, two other compounds were recorded in trace amounts but were not identified.

Alcohol fraction. The alcohols present as esters in the montan wax were converted to acid salts by heating with

soda lime and potassium hydroxide prior to esterification with methanol and sulphuric acid[4]. The normal, straight-chain compounds C_{10}–C_{21} were detected in amounts increasing from C_{10} to C_{18}, and decreasing from C_{18} to C_{21}. These compounds were also identified by the linear relation between log retention-time and carbon number.

Two further series of compounds were noted as present in the alcohol fraction, and from the close similarity of their retention times to those of the normal straight-chain series, it is concluded that these are related compounds.

Temperature Dependence of Irradiation Damage to Polythene

In the course of work on radiation damage to polythene using the Woolwich 4·3 MeV linear accelerator, it was observed that a dose of 1,000 megarep raised the elastic modulus of 'Alkathene 7' by a factor of three without apparently affecting crystal content. This was confirmed both by an X-ray diffraction analysis of the material[1] and by a spherulite analysis. The density of the material was also found to have increased by 0·95 per cent.

These results are to be compared with those obtained by Charlesby and Hancock[2] using the B.E.P.O. reactor, where an equivalent dose[3] of 22 pile units was found to destroy all crystallinity and to create a product with elastic modulus lower than original. This was shown to be the net result of an initial sharp fall in modulus up to a dose of 7 units due to rapid destruction of crystallinity followed by partial recovery due to radiation cross-linking of the now fully amorphous material. Full recovery occurred at 30 units dose and continued irradiation then increased the modulus above original.

The difference between accelerator and reactor results is almost certainly not due to differences in the quality of the respective radiations. Charlesby[4] has considered the effect of ionizing radiation in some detail and concludes that the ionizing effect of direct collision of neutrons with atoms is relatively very small. He further shows that there is little difference in the effects produced by different radiations of equivalent absorbed energy.

This being so, the most likely factor to influence the nature of the radiation damage from accelerator and reactor appears to be the temperature at which irradiation is carried out. In the case of the accelerator, specimen temperature does not exceed 30° C whereas, with a nuclear reactor, heat from the unit can raise the specimen temperature to near its melting point. At these elevated temperatures, polythene is intrinsically more amorphous due to partial melting of the crystalline component, and it seems reasonable that radiation cross-linking of the amorphous increment at an elevated temperature will prevent it recrystallizing on return to normal temperature. This would result in an apparent destruction of the crystalline component although the mechanism would still be the simple one of cross-linking, common to both types of radiation.

Work is proceeding to examine the effect of X-rays on polythene at elevated temperatures. If the suggested temperature dependence is established, we have clearly a method of directly raising or lowering the elastic modulus of polythene by irradiation with the same dose but at the appropriate temperature.

BIOCHEMISTRY

Total Synthesis of Adrenocorticotrophic Hormone

The total synthesis of β-corticotropin (ACTH), with the amino-acid sequence characteristic of the porcine species[1] (Fig. 1), has been achieved[2] using methods especially designed and developed for preparing large and complicated peptides[3]. They are: (*a*) formation of peptide bonds mainly by means of active esters[4] (for example, *p*-nitrophenyl esters[5,6]); (*b*) protection of amino and carboxyl functions with such blocking groups derived from *t*-butanol that easily can be removed in the last stage of the synthesis without destruction of sensitive peptides[3].

The latter method has proved to be essential for success, because ACTH is prone to severe alteration under conditions necessary for removing other, more common protecting groups such as carbobenzoxy[7], formyl[8], acetyl[8], and tosyl[9]. We also have successfully applied it to the syntheses of α-melanotropin (α-MSH) (ref. 10), β-melanotropin (β-MSH) (refs. 2, 11), and of β^{1-24}-corticotropin (the peptide comprising the *N*-terminal 24 amino-acids of ACTH) (ref. 12) as well as of other, similar peptides (β^{1-16}-corticotropin (ref. 13), β^{1-19}-corticotropin (ref. 14), Ac-Ser[1] β^{1-19}-corticotropin (ref. 15), etc.).

The synthetic route to ACTH starts from L-phenylalanine *t*-butyl ester (pos. No. 39) and proceeds in a stepwise manner by addition of one appropriately substituted amino-acid *p*-nitrophenyl ester after the other (removal of carbobenzoxy groups by hydrogenation, usually in 80 per cent acetic acid with palladium on charcoal; the resulting acetate salts may be reacted with the active ester to follow without addition of base) to the protected pentadecapeptide (pos. No. 15–39, Fig. 2). This compound, obtained in a pure state by counter-current distribution, was then reacted with the protected octapeptide (pos. No. 17–24) by the method of mixed anhydrides (mixed anhydride with trimethyl-acetic acid). The resulting derivative (pos. No. 17–39) was purified by counter-current distribution ($CHCl_3$, CCl_4, MeOH, 0·05 M NH_4OAc, pH = 6·5; 5 : 5 : 8 : 2 vol.; K = 2·3), hydrogenated and condensed with the azide of the protected hexapeptide (pos. No. 11–16) (ref. 16). The resulting protected nonacosapeptide (pos. No. 11–39) was extensively purified by counter-current distribution in the same solvent system (K = 0·8) and hydrogenated. Condensation with the decapeptide derivative (pos. No. 1–10) (ref. 17) by means of di*cyclo*hexyl carbodiimide gave a crude, protected nonatriacontapeptide which was purified by counter-current distribution ($CHCl_3$, CCl_4, MeOH, 0·1 M NH_4OAc, pH = 6·5; 8 : 8 : 17 : 7 vol.; K = 1·1). The purification by counter-current distribution was followed by chromatography on thin layers of alumina in the solvent system 100 (ref. 10) (Fig. 3). Material from the pure fractions was then treated with trifluoroacetic acid to remove all protecting groups and converted to the acetate salt. The

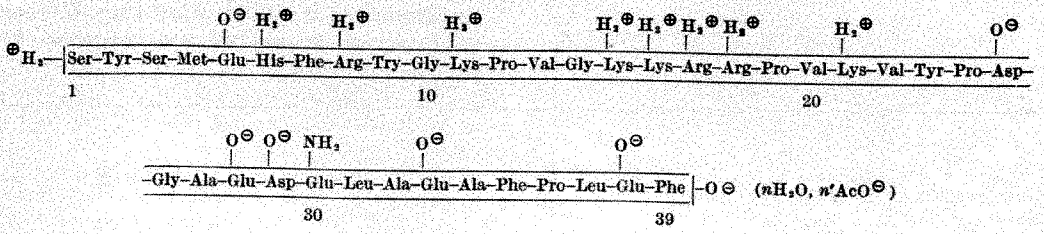

Fig. 1. Primary structure of porcine β-corticotropin (ACTH)[1]. (In natural material, water and acetate were estimated to be present in quantities of $n = 32$, $n' = 2$.) Abbreviations for amino-acids are those suggested by the Fifth European Peptide Symposium (Oxford, 1962); in particular: dashes extending above the symbols indicate loss of H— (on a nitrogenous group in the side-chains of basic amino-acids) or of —OH (from side-chain carboxyls) and replacement of these particles by groups symbolized in the formulæ

resulting compound was found to be pure by thin-layer chromatography on silica gel, $R_F = 0{\cdot}4$, solvent system 101 (ref. 10) (Fig. 3). It was identical with natural ACTH derived from porcine sources with respect to R_F-values, colour reactions (Ehrlich, Pauly, Ninhydrin, Sakaguchi) and biological activity (110 U.S.P.-U per mg). Ratio Tyr/Try = 2 : 1 (ultra-violet). Amino-acid ratios in the total hydrolysate (calculated values in parentheses; method of Spackman, Stein and Moore[16]):

Ala 3·0 (3·0); Arg 3·3 (3·0); Asp 2·1 (2·0); Glu 5·2 (5·0); Gly 2·9 (3·0); His 1·0 (1·0); Leu 2·0 (2·0); Lys 4·0 (4·0); Met 1·1 (1·0); Phe 2·8 (3·0); Pro 3·8 (4·0); Ser 1·9 (2·0); Tyr 2·1 (2·0); Val 3·0 (3·0); NH_3 1·8 (1·0).

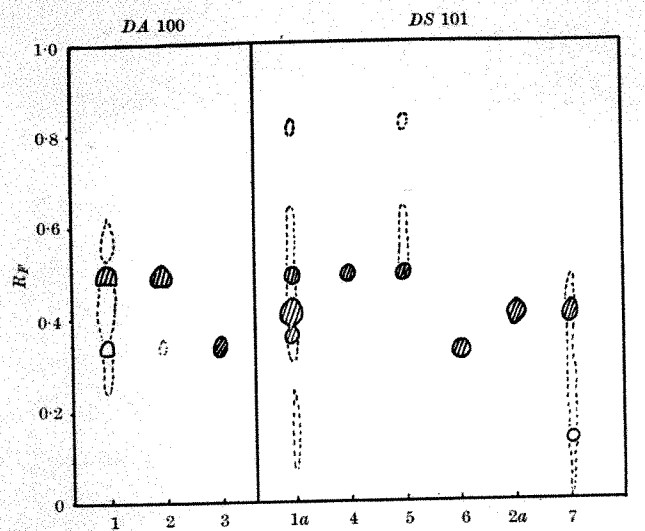

Fig. 3. Thin-layer chromatography of ACTH-peptides on alumina (*DA*) or silica gel (*DS*). Solvents Nos. 100 and 101 (ref. 10) stain according to Greig and Leaback (ref. 19). (1) Crude, protected nonatriacontapeptide; (2) protected nonatriacontapeptide after counter-current distribution; (3) sulphoxide of protected nonatriacontapeptide; (1*a*) crude, protected nonatriacontapeptide cleaved with F_3CCOOH; (4) β^{1-16}-corticotropin; (5) β^{1-16}-corticotropin treated with di*cyclo*hexyl carbodiimide; (6) β^{11-39}-corticotropin; (2*a*) synthetic ACTH: (2) treated with F_3CCOOH; (7) natural ACTH (Wilson Laboratories, Chicago), 95 U.S.P.-u/mg

Detailed physico-chemical, chemical, biological and immunological investigations are under way. A report on the details of the synthesis is being prepared[20].

The consequent development and application of new protecting groups has thus enabled the synthesis of all three types of hormone of the anterior and median lobes of the pituitary the primary structure of which is known: α-MSH, β-MSH and ACTH. For the synthesis of still longer chains, one may certainly rely on these protecting groups, but more effort will have to be put into the development of even better schemes and methods for the linking together of amino-acids and peptides.

This communication is dedicated to Prof. Hans Pallmann on the occasion of his sixtieth anniversary.

Isolation of a Sialic Acid-rich Glycoprotein Fraction from Normal Human Urine

In a previous investigation[1], I subjected the non-ultrafilterable substances from normal urine to preparative zone electrophoresis at *p*H 8·6 and 4·5 and described a urinary glycoprotein fraction which had a high mobility towards the anode at both *p*H's. The mobility at *p*H 8·6 was similar to that of albumin, and the material was characterized by a relatively high sialic acid content and a relatively small peptide content[1]. It is the purpose of the present communication to report on the isolation and partial chemical characterization of this sialic acid-rich glycoprotein fraction.

Five-litre aliquots of pooled normal male urine were concentrated 700–1,000 times by ultra-filtration (cf. ref. 2). 'Visking' dialysis tubing of 23/32-in. inflated diameter was used as the filtering membrane. This membrane has been found to retain completely substances with molecular weights above 10,000–15,000[2]. One of the concentrated urines was separated by electrophoresis on a 'Pevikon' block at *p*H 8·6, and the distribution of protein and different carbohydrates following electrophoresis was determined[2].

The albumin zone obtained after such a separation contains the sialic acid-rich glycoprotein fraction and, in addition, a uronic acid-containing mucopolysaccharide fraction[1]. The eluates containing the maximum and the fast-moving part of the albumin peak were concentrated to a small volume by ultra-filtration and the concentrated material was subjected to zone electrophoresis at *p*H 4·5 (cf. ref. 1). At this *p*H the albumin migrated towards the cathode whereas the sialic acid-rich fraction and the mucopolysaccharide material moved towards the anode.

These two substances were almost completely separated, the mucopolysaccharide material having the higher anodal mobility. Small amounts of glycoprotein substances were distributed between the albumin and the sialic acid-rich glycoprotein fraction. The eluates containing the sialic acid-rich material were combined, concentrated, and subjected to electrophoresis at *p*H 8·6. The protein and carbohydrate curves obtained after the electrophoretic separation are shown in Fig. 1. It can be seen that the material gave a fairly symmetrical peak, and that the ratio sialic acid ('Bial') : hexose + methylpentose (orcinol) : protein ('Folin') was similar throughout the peak. The eluates containing the peak were pooled, dialysed against repeated changes of distilled water, and lyophilized. The yield of lyophilized material was about 1 mg/l. pooled urine. The dried material was analysed for sialic acid, hexose, fucose, hexosamine, and nitrogen with methods adopted earlier[2].

The composition is given in Table 1 (prep. No. I).

The two other preparations listed in Table 1 were isolated in somewhat different ways; prep. No. II by a series of three electrophoretic separations at *p*H's 4·5, 4·5, and 8·6, and prep. No. III by two successive separations

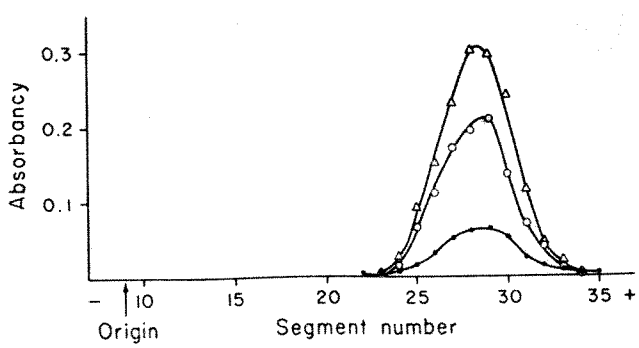

Fig. 1. Sialic acid-rich urinary glycoprotein fraction. Distribution of sialic acid ('Bial', Δ), hexose and methylpentose (orcinol, ○), and protein ('Folin', ●) after zone electrophoresis at *p*H 8·6

at *p*H 4·5. As can be seen, all three preparations had a similar composition. The neutral sugars present in prep. No. I were examined by one-dimensional paper chromatography, using the solvent system *n*-butanol–pyridine–water[2]. It was found to contain predominantly galactose with small amounts of mannose and fucose. Prep. No. I was also assayed for uronic acid with the carbazole method (cf. ref. 2) and was found to contain less than 1 per cent of this monosaccharide. A substance which was purified in the same way as prep. No. I was analysed in the Spinco ultracentrifuge model *E* at a protein concentration of 0·8 per cent in acetate buffer, *p*H 5·0. The sedimentation coefficient for the main part of the glycoprotein material was $s^{0.8\%}_{21,w} = 2{\cdot}5\ S$. The rest of the material sedimented more slowly as judged by the somewhat assymmetric appearance of the sedimentation patterns.

Table 1. Composition of Sialic Acid-rich Urinary Glycoprotein Fraction*

Preparation No.	Sialic acid	Hexose	Fucose	Hexosamine	Nitrogen
I	28·6	15·8	1·3	16·7	4·6
II	24·2	14·9	1·1	16·9	6·7
III	29·9	16·6	1·5	12·3	6·0

* Percentage dry weight (the materials were dried *in vacuo* at 80° for 48 h). The figures are uncorrected for ash and residual moisture content.

Urinary glycoprotein fractions that resemble the material reported in the present communication have recently been described by Bourrillon *et al.*[3]. Furthermore, Eylar[4] has given a preliminary account for the isolation from normal human serum of carbohydrate-rich glycoproteins with chemical compositions that coincide closely with that of the urinary glycoprotein fraction just described. It will be of interest to establish the relationships between these serum glycoproteins and the sialic acid-rich urinary glycoprotein fraction.

Quantitative Relations between Ferritin and Siderin

Information about age-conditioned changes of the quantity of ferritin and total iron in human livers[11,12] has led to the conclusion that a strong quantitative correlation exists between ferritin and siderin. Several experimental investigations[1–8,14,16–19] support this conception. So far, however, there has been no special proof for the human liver.

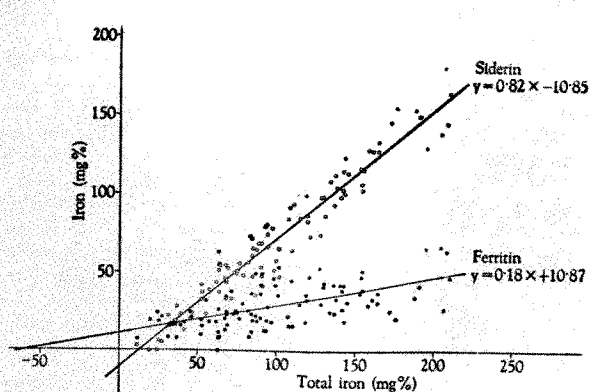

Fig. 1. Average value curve of siderin- and ferritin-iron (mg per cent) in relation to total iron of liver. All values are related to liver dry weight. Regression coefficient of single values:

$r_{calc.,\ ferritin} = 0{\cdot}59$; $r_{calc.,\ siderin} = 0{\cdot}95$
$r_{table,\ f=100} = 0{\cdot}25$; $r_{table}/r_{calc.}$ = significant

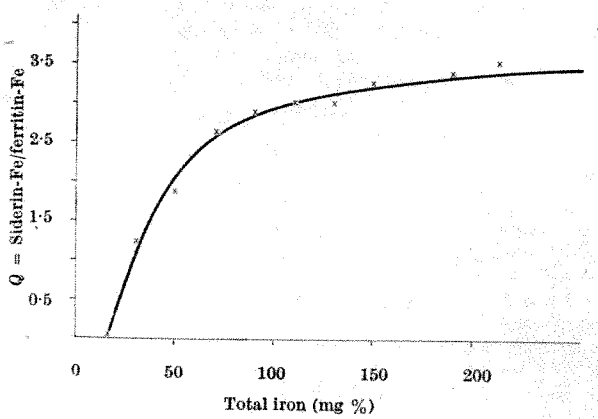

Fig. 2. Quotient of siderin-iron/ferritin-iron in relation to liver total iron

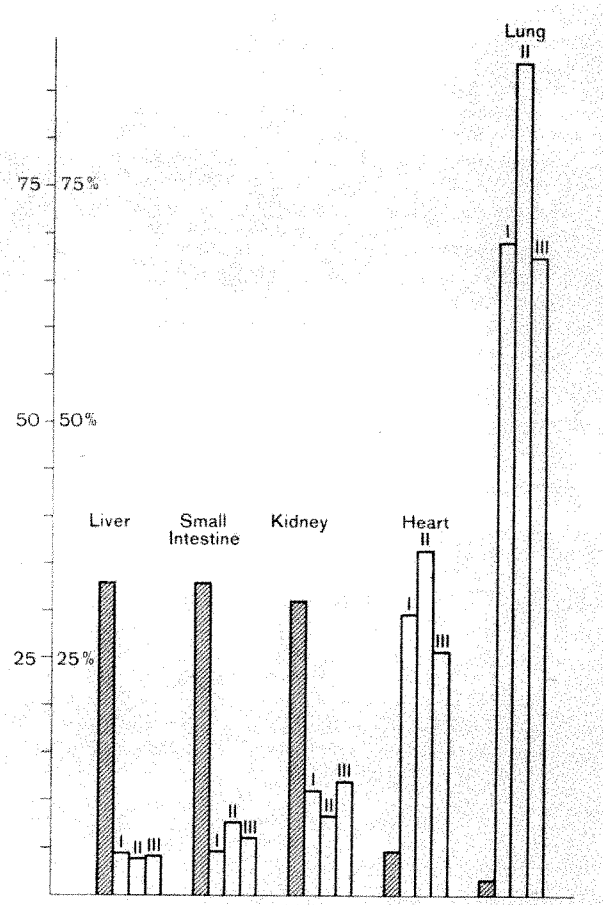

Fig. 3. Siderin-iron/ferritin-iron quotient (white columns) of different organs with transfusional hæmosiderosis in relation to protein metabolism (per cent) (ref. 13) (shaded columns) of these organs

We have examined 136 human livers with respect to quantitative relationships between ferritin and siderin. In preliminary experiments with eight livers from healthy men we compared the method for siderin estimation of Gabrio, Shoden and Finch[3] with the procedure of Wöhler, Otte and Schmidt[20]. We found no significant difference with $t_{calc.} = 0{\cdot}082$, $t_{tabl.} = 2{\cdot}260$. We performed siderin estimations according to the method of Wöhler[20]; ferritin, total-iron and hæmoglobin estimates were made following methods used in former investigations[11,12].

Our investigations of siderin content and ferritin content in 99 human livers from males with siderosis show that, with the elevation of total-iron, siderin- and

ferritin-iron rise in a similar way. It seems that a dynamic equilibrium exists between siderin and ferritin. Fig. 1 demonstrates that the effect on ferritin-iron is much smaller than on siderin-iron.

The view that there exists an equilibrium between siderin and ferritin is supported by Fig. 2. Here we have illustrated the quotient siderin-iron/ferritin-iron. It shows that in a range of about 100–150 mg per cent total iron the curve tends to approach asymptotically a constant value of the quotient. In this respect we do not agree completely with the results of the experiments of Shoden *et al.*[3,14,15].

A further confirmation of the supposition of a constant proportion siderin-iron/ferritin-iron resulted from the investigation of three cases with transfusional hæmosiderosis. We found that, although total iron rises to 1,400 mg per cent, the quotient of siderin-iron/ferritin-iron lies constant between 2·0 and 3·0. This fact demonstrates that even in the case of excessive iron storage the liver is able to produce in relation to siderin an aliquot part of ferritin-iron, if protein metabolism is normal.

With respect to protein metabolism, we observed by quantitative ferritin and siderin estimation of several organs in the three cases with transfusional siderosis that the quotient siderin-/ferritin-iron values change with the levels of protein metabolism. Fig. 3 shows these proportions in comparison with the height of protein metabolism.

Our results demonstrate that, under physiological conditions, ferritin-iron storage of liver has no absolute limit. In agreement with Keiderling and co-workers[7,8], Kettler[9], Wöhler and Zoll[21] and Zizza and Block[22], we see a limiting factor on one hand in an alteration of protein metabolism, and on the other in a change of oxidative metabolism in the liver, especially through changes in oxidative phosphorylation[10].

Acid Ribonuclease in Liver Cell Sap

The acid ribonuclease of rat liver cytoplasm is located mainly in particles ('lysosomes'), and shows 'total' activity only if a treatment such as freezing and thawing is applied[1,2]. However, as much as one-quarter of the cytoplasmic activity is found in the supernatant fraction from liver homogenates, even with a centrifugal force as high as 105,000*g*. This supernatant-fraction activity, expressed per gm of tissue, is markedly increased in the case of hepatomas[3,4], precancerous liver from rats fed an azo dye[3], or liver from adrenalectomized rats[5]. De Duve[1] showed that autolysis likewise leads to increased supernatant-fraction activity of lysosomal enzymes, but remarked that the results "have been obtained on homogenates and it remains to be seen to what extent they apply to the cells themselves"; obviously an increase in supernatant-fraction activity could be attributed to increased fragility of lysosomes.

One cause of partial rupture of lysosomes might be exposure to an artificial medium as used for homogenizing; but it should be noted that the acid-ribonuclease activity of the supernatant fraction is of the same order with a dextran–raffinose medium as with the conventional 0·25 M sucrose medium[2]. Another cause might be mechanical damage to the lysosomes; but the following observations render this possibility unlikely.

Suppose that little activity is present in the cell sap *in vivo*. Then *mild* homogenization with a conventional Potter–Elvehjem homogenizer and subsequent removal of nuclei and unbroken cells at 600*g* should give, in somewhat low recovery, a cytoplasmic fraction containing lysosomes which had been little exposed to shearing; the supernatant fraction thereafter obtained by high-speed centrifugation might then show very low activity compared with the total activity of the cytoplasmic fraction. (Shearing during the centrifugation as distinct from the homogenization is probably negligible; supernatant-fraction activity was in fact undiminished when, in one experiment, the usual angle head was replaced by a swing-out head to reduce 'wall effects').

An initial experiment showed that the activity, in both the cytoplasmic and the supernatant fraction, was as high after one up-and-down stroke of the pestle (rotating at 2,000 rev./min) as after 16 strokes. Precancerous liver behaved similarly to normal liver. If, then, lysosomes are damaged in the homogenizing process, there must be a ceiling to the damage.

In further experiments, one-stroke ('mild') homogenizing at only 500 rev./min was compared with 5-stroke ('drastic') homogenizing at 2,000 rev./min, and found to give only about half as much cytoplasmic (total) activity. In both normal and experimental rats, the supernatant-fraction activity of acid ribonuclease, relative to the total activity in the cytoplasm, was no lower for mild than for drastic homogenizing (upper portion, Fig. 1). Some experiments included assays for glucose-6-phosphate dehydrogenase, an enzyme which is present in the supernatant-fraction but not in cytoplasmic particles[6]. The supernatant-fraction activity of acid ribonuclease, relative to that of this dehydrogenase, was again no lower for mild than for drastic homogenization; indeed, mild homogenization tended to give disproportionately high ribonuclease activity in the case of precancerous liver and liver tumours (lower portion, Fig. 1). In experiments such as these, there is the possible complication that cell constituents may have leaked, to an extent depending on the constituent, from the 'unbroken' cells which remain after mild homogenization, as has been found with liver cell suspensions[7].

It seems unlikely that limited release of ribonuclease from lysosomes would occur abruptly during homogenization. It would appear, therefore, that acid ribonuclease as found in supernatant fractions is indeed present in the cell sap *in vivo*. For normal rats as examined in this

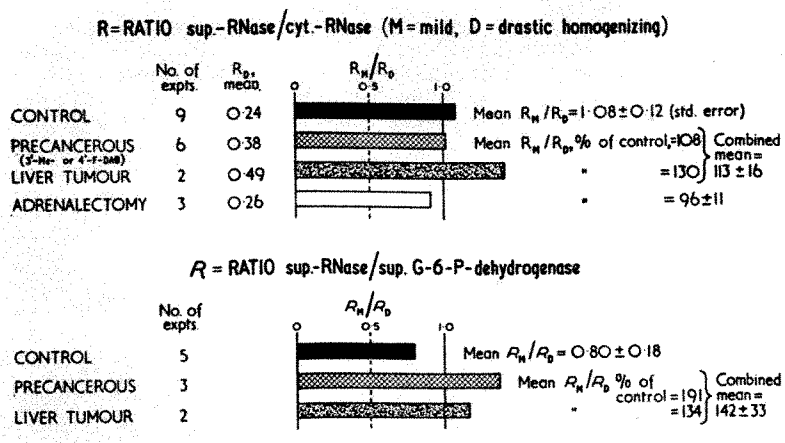

Fig. 1. Acid ribonuclease (RNase) activity in supernatant (sup.) fractions, compared with that in cytoplasmic (cyt.) fractions subjected to freezing and thawing, and with glucose-6-phosphate dehydrogenase (G-6-P-dehydrogenase) activity. Precancerous liver was obtained by feeding 3'-methyl- or 4'-fluoro-4-dimethylaminoazobenzene for 3–7 weeks, and primary tumours were obtained by prolonged feeding of the former compound. Adrenalectomized rats were maintained on saline and were killed 2–3 weeks after operation; cyt.-RNase as well as sup.-RNase is then increased[5], hence the value for R_D, mean is little above normal. All rats were male albinos, and were fasted overnight before killing. For preparation of homogenates, see text; in some experiments the 0·25 M sucrose medium was supplemented with *p*H 8·0 *tris* buffer (to 0·01 M) and with ethylenediamine tetraacetate (to 0·001 M), but no difference in the results was evident. Each experimental rat was compared with a control done side-by-side, and the R_M/R_D value calculated as percentage of that for the control; the mean values given for 'percentage of control' are therefore not based on the histogram representing all controls.

laboratory the ratio of supernatant-fraction activity to cytoplasmic (total) activity has consistently been, as illustrated elsewhere[2], somewhat higher for acid ribonuclease than for the classical lysosomal enzyme, acid phosphatase. Some preliminary evidence has been obtained (in collaboration with Mr. A. B. A. El-Aaser) that the activity in supernatant fractions may in part be due to an enzyme different from that in lysosomes.

The work was supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the Medical Research Council, the British Empire Cancer Campaign, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

Further Separation of Iodine, Monoiodotyrosine and Diiodotyrosine by means of Modified Charcoal

A method for the separation of iodide from iodotyrosines extracted with Blau's alkaline reagent (4 N sodium hydroxide in 5 per cent sodium carbonate) from *n*-butanol extracts of thyroid hydrolysates by means of modified charcoal was previously described[1]. This method suffered from the following shortcomings: removal of traces of butanol from the alkali wash was quite difficult, and, since the butanol interfered with the adsorption of the iodotyrosines on the charcoal, repeated treatment of the alkali with the charcoal was required; the adsorbed iodotyrosines could be eluted from the charcoal *in toto*, but could not be separated into mono- and di-iodotyrosines. This communication deals with further developments of the method to overcome the foregoing handicaps.

The charcoal was modified with stearic acid as described before[1]. It was found, however, that the previously mentioned failure to elute the iodotyrosines from the stearic acid-modified charcoal was due to incomplete washing of the carbon to remove all the ethanol present. When the charcoal was washed carefully after being modified with stearic acid, no further treatment with tyrosine was necessary, and this step was therefore omitted. 5 g of the stearic acid-modified charcoal in 50 ml. Blau's reagent constituted the 'charcoal reagent'. The charcoal reagent was allowed to stand for at least overnight before use. The reagent could be kept unchanged for as long as a month.

5 ml. of *n*-butanol extract of thyroid hydrolysate, or of serum, was washed three times with 5 ml. of Blau's alkali reagent. The butanol carried over in the combined alkali washings was extracted with 15 ml. of chloroform. After allowing 1 h for the separation of the layers, an aliquot of 10 ml. of the upper, alkali layer was pipetted into a test-tube and thoroughly mixed with 12 drops of well-shaken charcoal reagent. The charcoal was precipitated by centrifugation and the alkali supernate was treated with additional charcoal reagent in a second test-tube. Up to 98 per cent of the iodotyrosines were thus adsorbed with no difficulty. The alkali supernate, containing the iodide, was quantitatively transferred into a volumetric flask and made to volume for radioactive or chemical analysis. A long-stem funnel of 7 cm diameter was then fixed in a Büchner-type filter tube with side-arm connected to a vacuum pump. A glass-wool plug was fitted into the top of the funnel stem, suction was applied and 'Celite', suspended in distilled water, was poured on to the plug to form an evenly distributed layer of about 2 mm in thickness. Next, the two precipitated carbons were suspended in alkali reagent and transferred to the funnel. This step was repeated as many times as necessary until the charcoal was quantitatively transferred to the funnel. When all the alkali passed through, the funnel with its contents was switched on to another filter tube.

Two solvents were prepared for eluting the mono- and di-iodotyrosines: a 1·25 per cent alcoholic–alkali solution—to 1·25 ml. of absolute ethanol was added Blau's alkali reagent to make a total volume of 100 ml.—and a 3 per cent alcoholic–alkali solution, prepared in a similar fashion. The monoiodotyrosine (MIT) was eluted with suction by 3 volumes of 10 ml. each of the 1·25 per cent alcoholic–alkali solution. The funnel was then set in another filter tube and the diiodotyrosine (DIT) was eluted with three 10 ml. volumes of 3 per cent alcoholic–alkali. The eluting solvents had to be thoroughy shaken immediately prior to elution, otherwise an uneven mixture of alcohol and alkali resulted.

Pure solutions containing a mixture of MIT and DIT in Blau's reagent were treated with charcoal reagent as described here, and the two iodotyrosines were separated by elution. Each eluent was neutralized in the cold with 10 per cent sulphuric acid and small volumes were chromatographed on paper using *n*-butanol/acetic/water (78 : 5 : 17) as solvent[2]. The results of the chromatographic analysis showed that a complete separation of MIT and DIT was effected. The spots on the paper were revealed as recommended by Bowden *et al.*[3] with the following exceptions: 0·1 N Ce^{+4} in 5 N sulphuric acid and 0·3 N $H_2AsO_3^-$ in N sulphuric acid[4] in a ratio of 1 : 1 was used to detect as little as 0·05 I^- per spot. Sheets of

'Parafilm' were placed between the papers and the glass plates to form a 'double-decker sandwich'. The spots could then be cut out, paper and 'Parafilm', with no contamination or losses, and placed in test-tubes for radioactive counting, or for chemical analysis. The chemical analysis of the alcoholic–alkali eluents, by means of an arsenious–cerate method to be described elsewhere, showed that the iodothyrosines were recovered quantitatively in comparison to standard solutions treated in an identical manner.

A stand which could hold a series of 6 filter tubes and funnels was constructed, and this permitted the handling of 6 samples at a time.

Thyroids of rats injected with iodine-131 were digested with alkali as before[1]. It was noticed that a large percentage of the adsorbed activity remained on the charcoal after elution. Longer alkaline digestion of the glands resulted in a decrease of the uneluted fraction, suggesting that the uneluted fraction was probably undigested peptides and polypeptides and indicating that the time of hydrolysis, namely 4 h, was inadequate. Longer periods of hydrolysis caused much deiodination. Thyroid glands of rats injected with iodine-131 and hydrolysed enzymatically[2] were analysed by the method described here and found to contain: 12 per cent I^-; 10 per cent iodothyronines; 20 per cent MIT; 38 per cent DIT; 15 per cent unhydrolysed peptides (that is, a fraction which remained uneluted). These results are comparable with those commonly obtained by paper chromatography.

The use of the method described here offers the following advantages: it saves time; very low iodine-131 activities need to be injected (0·5 μc./rat); it is fairly simple and requires no specialized equipment; it yields results which are easy to come by. The ethanol present in the alcoholic–alkali eluent can be evaporated by bubbling nitrogen through, and the resulting Blau's solution can be treated again with the charcoal reagent. The adsorbed MIT, or DIT, can then be eluted with water. This is of particular interest for preparative purposes of pure MIT or DIT.

Free Amino-acid Content of Tobacco-seeds

Although much has been published about the various aspects of tobacco leaves, the same cannot be said about tobacco seeds. As regards organic nitrogen compounds in tobacco seeds, Abdoh and Taufel[1] have produced evidence for the existence of pyridine derivations in mature tobacco seeds.

Il'in and Lovkova[2] have found a high level of free amino-acids in immature tobacco seeds, but supposedly have found only bound amino-acids in the mature seeds. These authors assume that a direct relation exists between the biosynthesis and decomposition processes of nicotine and nitrogen metabolism in tobacco plants.

This communication attempts to show the existence of a number of free amino-acids in mature tobacco seeds, especially in seeds of tobacco grown in Iran.

The mature seeds (which were 1·5 years old) from three species of Iranian tobacco plants—*Nicotiniana basmacerus*, *N. trabzant*, *N. tikolak*—acclimatized to the northern areas of Iran were used in this work.

The seeds were first ground in a porcelain pestle and mortar, then extracted with 80 per cent ethanol in the mortar. Chloroform was added to the filtrate and shaken in a separatory funnel. The chloroform layer was discarded. This chloroform washing was repeated three times. The resultant water solution was then examined for the presence of amino-acids by paper chromatography. To the top layer 1/10 volume of isopropanol was added and samples of the resultant were applied to Whatman

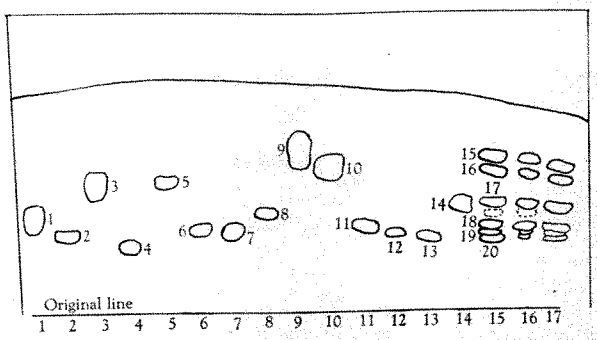

Fig. 1. First test: 1, tyrosine; 2, glycine; 3, methionine; 4, histidine; 5, proline; 6, serine; 7, arginine; 8, threonine; 9, leucine; 10, valine; 11, glutamic acid; 12, aspartic acid; 13, lysine; 14, alanine; 15, leucine; 16, valine; 17, alanine; 18, glutamic acid; 19, aspartic acid; 20, arginine

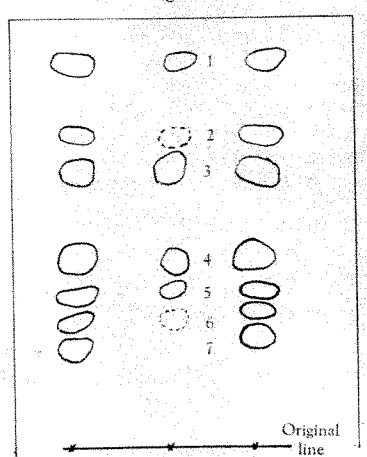

Fig. 2. Second test: 1, leucine; 2, valine; 3, alanine; 4, glutamic acid; 5, aspartic acid; 6, arginine; 7, lysine. Solvent—*n*-butanol/acetic acid/water = 250 : 60 : 250 v/v/v—upper layer is used

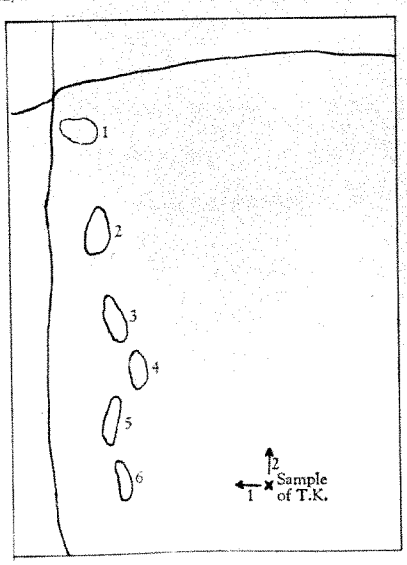

Fig. 3. Third test: 1, leucine; 2, valine; 3, alanine; 4, arginine; 5, glutamic acid; 6, aspartic acid. Solvent 1—*tert.*butanol/formic acid/water = 70 : 15 : 15 v/v/v for 29 h. Solvent 2—phenol/water = 400 : 100 w/v in atmosphere of ammonia for 20 h

er. Concurrently, 14 amino-acids (Merck) were on the same paper. For these Merck amino- solvent was 10 c.c. *tert.*butanol, 15 c.c. 98 per nic acid, 15 c.c. water. The chromatogram was l with ninhydrin reagent after 20 h.

ve found for each of the three species of tobacco x amino-acids, characterized as leucine, valine, glutamic acid, aspartic acid and arginine. An in spot appeared in the place for lysine, but to be this was repeated using a solvent of acetic acid, nol and water. The seventh point repeated itself ine.

lysine and valine spot for the *N. trabzant* seed was weak. The lysine spots for *N. tikolak* and *N. bas-us* were also weak.

confirm the foregoing results, a two-dimensional natogram was run. In the first dimension, the nt was *tert.*butanol, formic acid and water, and in the nd dimension the solvent was 400 g phenol, 100 c.c. er in an atmosphere of ammonia 20 c.c. 0/3 per cent nonia solution. The result of the two-dimensional omatogram showed the existence of six amino-acids: cine, valine, arginine, glutamic acid, aspartic acid and anine. Lysine did not appear in this chromatogram erhaps because its quantity was too scarce to be stained fficiently for detection.

The results show that at least 6 amino-acids do exist in he free state in mature tobacco seeds of some species. Further, 4 or 5 of these free amino-acids are among the essential amino-acids for animals, for example, rats.

We thank the Agricultural Tobacco Experimental Farm, Tirtash, of the Iranian Tobacco Monopoly, especially Engineer Saphir Paulus, director of the Experimental Farm, for the supply of tobacco seeds.

Intermediary Metabolism in Bull Semen

We have examined the incorporation of radiocarbon from [^{14}C] glucose, [2-^{14}C] acetate and [1 : 4-$^{14}C_2$] succinate into the soluble metabolic intermediates of bull semen. Samples (50 μl.) of the semen, used within 6 h of collection, were mixed with 50 μl. of a solution containing 0·1 mM adenosine triphosphate, 2 mM magnesium sulphate, 10 mM potassium chloride and 1 μc. of the labelled substrate dissolved in 0·1 M potassium phosphate buffer, *p*H 7·4. The mixtures were incubated aerobically at 37° C for 30 min. At the end of the incubation period the enzyme systems were inactivated by the addition of 400 μl. of boiling ethanol and the mixtures centrifuged at 500*g*. The radioactive substances present in the supernatants were separated by two-dimensional paper chromatography, visualized by autoradiography and the carbon-14 measured by the techniques described by Smith and Moses[1].

The results (Table 1) show that whole bull semen utilized 99 per cent of the labelled glucose and that radiocarbon was incorporated mainly into hexose phosphates and lactate. Redenz[2] has shown that bull spermatozoa are able to glycolyse various sugars, including glucose, to lactate, and it has become an established fact that the metabolism of spermatozoa in several mammalian species is predominantly of a glycolytic character[3]. The presence of radioactivity in fructose is explicable because the initial product of glycolysis, glucose-6-phosphate, is readily converted by spermatozoal phosphohexose isomerase to fructose-6-phosphate, which may form fructose as a result of the action of phosphatase enzymes in the seminal plasma.

Table 1. Metabolism of Labelled Substrates by Bull Semen
Results given as ^{14}C (counts per min × 10^{-2}) incorporated into each soluble intermediate

[^{14}C] Glucose		[2-^{14}C] Acetate		[1:4-$^{14}C_2$] Succinate	
Intermediate	^{14}C	Intermediate	^{14}C	Intermediate	^{14}C
Hexose phosphates	29	Lactate	90	Fumarate	113
Fructose	2	Alanine	1	Malate	330
Lactate	16	Glutamate	3	Citrate	1
% of labelled glucose utilized	99	Glutamine	9	Aspartate	1
		Citrate	4	Glutamate	1
		Succinate	1	% of labelled succinate utilized	67
		Fumarate	2		
		Malate	5		

Most of the incorporated isotope from the labelled acetate was found in lactate which was presumably formed via pyruvate and acetylcoenzyme *A*. The preponderance of labelled lactate over labelled alanine in both the radioactive glucose and acetate experiments suggested that transamination of pyruvate does not occur to any appreciable extent in bull semen. In the acetate and succinate experiments only small amounts of radiocarbon were incorporated into aspartate and glutamate, and Bhargava, Bishop and Work[4] have shown that the intracellular amino-acid pools of bull spermatozoa are low compared with those in other mammalian tissues. However, the presence of radioactive glutamine in the acetate experiments shows that bull semen possesses glutamate synthetase activity. Succinic acid has been reported to have little effect on the oxygen uptake of intact mammalian spermatozoa[3]. In the work recorded here, the bull semen was found to utilize 67 per cent of the labelled succinate; but the incorporated radiocarbon accumulated in fumarate and malate, with only trace amounts in aspartate, citrate and glutamate. These results suggest that bull semen possesses appreciable succinate dehydrogenase activity but only a very limited capacity to metabolize malate.

We thank the Medical Research Council for financial support and Mr. H. M. Dott for supplying the bull semen.

A Rapid Method of Disk Electrophoresis

Disk electrophoresis, as originated by Ornstein and Davis[1], provides a delicate analytical technique for the resolution of protein mixtures, but it requires nearly 2 h to complete a run. The formation of two acrylamide gels which merely prevent convection and take no direct part in the separation occupies some forty minutes. Barka avoided this step by simply layering the proteins in an appropriate buffer over the running gel[2]. Reisfeld[3] added sucrose to the sample mixture so that the density gradient diminished diffusion, but it has been reported that this manœuvre necessitates a reduced voltage during electrophoresis[4].

This communication describes a simple general procedure which gives a result in about 70 min. This same procedure enables electropherograms of the plasma proteins (as anions) to be obtained from capillary blood and, finally, some other applications are outlined.

A typical plasma protein electropherogram from equine whole blood is illustrated in Fig. 1*a*. To achieve this, the 'running gel' (*p*H 9·1) was formed in a glass tube exactly as described by Ornstein and Davis, but immediately before use it was overlaid with a 1-cm column of a buffer–

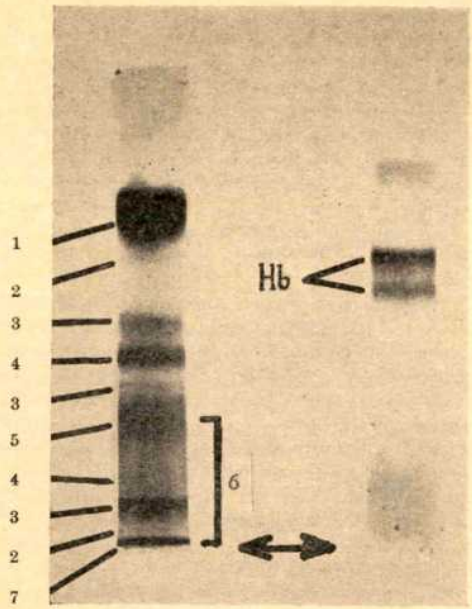

Fig. 1. Disk electropherograms obtained by the technique described in the text. The origins are indicated by ←→. *a*, Equine plasma; the numbered bands move with the following paper electrophoretic fractions: (1) Albumin, (2) α_1, (3) α_2, (4) β_1, (5) β_2 (6) region of γ-globulins and (7) fibrinogen (obscuring the β lipoprotein band); *b* An equine hæmolysate showing the typical hæmoglobin doublet (Hb) of this species

sucrose–'Sephadex' (Pharmacia, Uppsala, Sweden) mixture in place of the large pore acrylamide spacer gel.

The 'Sephadex' (grade *G*-200) had previously been washed with water, decanted and finally suspended in a 20 per cent w/v sucrose solution. The working mixture was prepared by diluting two volumes of the sedimented 'Sephadex' with one of *tris*–chloride buffer (*p*H 6·7, 180 mM with respect to chloride ions). Meanwhile, 30 μl. of the whole blood had been diluted with 0·5 ml. of the same *tris*–chloride buffer which is sufficiently near isotonicity to prevent lysis and the hæmic cells deposited by a brief centrifugation. To an aliquot of the supernatant was added two volumes of the sucrose–'Sephadex' suspension and a quantity of the resulting mixture was introduced into the gel tube to give a column 8 mm high. Although these 'Sephadex' mixtures may be dispensed like a liquid, the gel tubes can be safely inverted without mixing or loss, so that further manipulations followed the published technique. However, care was exercised in pouring the *tris*–glycine buffer into the upper tank lest the sample be dislodged; also, a hypodermic needle was used for the removal of the gel after running[3]. The gel was stained for 10 min in the amidoschwarz–acetic acid mixture and finally electrically cleared. The short staining time has been found to affect the electrophoretic pattern to a negligible extent, providing a permanent result is not required.

The use of 'Sephadex *G*-200'–sucrose mixtures instead of the large-pore acrylamide gels offers advantages in other fields. Equine hæmolysates inhibit polymerization, so preventing hæmoglobin separations. No such difficulty arises with 'Sephadex'. An appropriate volume of the hæmolysate is mixed with the 'Sephadex'–sucrose–buffer fluid, which is then processed as for plasma. Excellent resolution is attainable (Fig. 1*b*). The result is typical for the horse and confirms that equine hæmoglobin consists of at least two major components[5]. Nor is it necessary for the protein to be in solution, for disks punched from air-dried paper electrophoresis strips may be inserted in the 'Sephadex' column. The Kohlrausch boundary automatically elutes the protein so that normal fractionation follows. The relationship between paper and di
phoresis given in the legend to Fig. 1*a* was deriv
means.

Electron Microscope Examination of Myog

THE structure of myoglobin has been examin
means of X-ray analysis; I have now made an ele
microscopical investigation of this protein. Ther
however, a special reason why I have embarked o
work. Some authors report that they have occasio
encountered annular structures on electron micrograph
of larger globular proteins[1–4]. These findings, at lea
the case of hæmoglobin, do not agree with those of X
analysis. According to X-ray investigations the hæ
globin molecules should be represented on electron mic
graphs as nearly circular-shaped dots. The same ho
also for myoglobin, so I thought it should be of so
interest to find out whether annular structures are als
found on electron micrographs of a comparatively sma
protein, such as myoglobin, which consists only of on
Svedberg unit.

For the investigation of myoglobin in the electron
microscope a small droplet of an aqueous solution of the protein was deposited on a collodion-covered specimen grid, and shadowed with a very thin layer of tantalum. For another series of experiments osmium tetroxide was added to an aqueous solution of the protein. By careful

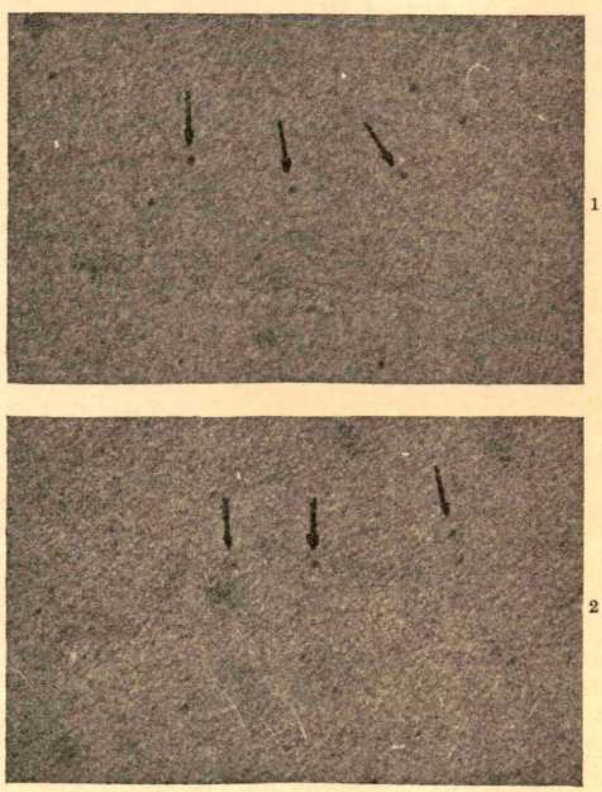

Fig. 1. Myoglobin molecules, shadowed. (× 200,000)
Fig. 2. Myoglobin molecules, osmium stained. (× 200,000.) Some molecules are indicated by arrows

dialysis all excess of osmium was removed, and again a droplet was deposited on a specimen grid. (For a more detailed description of this method see ref. 5.)

Figs. 1 and 2 show the results. The molecules are represented as small circular dots (diameter about 40 Å) and no annular structures were detected. These findings are in agreement with the results of X-ray analysis. Biological specimens are very delicate structures, and in the interpretation of electron micrographs the possibility of structural changes has always to be considered[6]. It is quite feasible that in some cases the Svedberg-units of some larger protein molecules (for example, hæmoglobin and albumin) are somewhat displaced as the result of specimen preparation and/or by the effect of the vacuum and of the electron beam. A small hole may thus be formed, giving rise to annular structures on electron micrographs. This concept seems to be supported by certain findings of Hall, who reports in an electron microscopical investigation that he found occasionally disintegration of protein molecules[7]. In view of the investigation reported here, and in view of the results of X-ray analysis, this interpretation appears to be more tenable than a tentative one put forward in a previous paper[1], which was based on the assumption that the 'hole' might be an intrinsic property of the Svedberg-unit. But I feel that electron microscopical investigations alone cannot completely prove or disprove a theory on the structure of proteins.

I thank Dr. John C. Kendrew, Laboratory of Molecular Biology, Cambridge, for providing the sample of myoglobin.

PHYSIOLOGY

Influence of Diet on Urine Concentration in *Aplodontia rufa* and the Rabbit

Urea plays an important part in the production of a concentrated urine in mammals[1]. Berliner *et al.*[2] postulate that urea contributes to the renal concentrating ability because it diffuses from the collecting ducts into the medullary interstitium and is trapped by capillary countercurrent exchangers, called vasa recta. Urea, therefore, increases the osmotic pressure of the medullary interstitial fluid with which the collecting duct fluid equilibrates during the formation of a hypertonic urine. Thus, increasing the available urea enhances maximum urine concentrating ability in most species which have been investigated (man, dog, rat, cat, kangaroo rat, and jerboa[3])

However, Schmidt-Nielsen *et al.*[3] showed that this is not true for certain species: pig, beaver, and gerbil. These workers could not correlate the difference in function with anatomical differences in the nephron populations of these three species. They expressed the hope that more work would be done to explain why diet does not affect the urine concentration ceiling in certain species.

The specialized capillaries of the renal medulla (vasa recta) are an important factor in the urine concentration process[4]. Those mammals with a fixed osmotic ceiling of the urine may possess vasa recta with a morphology different from those species the urine osmotic ceiling of which does change with diet. We therefore determined the effects of high and low nitrogen intake on urine concentration in two species with differing morphology of the vasa recta: *Aplodontia rufa* and the domestic rabbit.

In *Aplodontia* the vasa recta do not form loops[5]; but such loops are present in the medulla of the rabbit[6]. Both these species are similar in size and dietary habits, and can, therefore, be treated in a uniform manner. This is an important consideration because the three species investigated by Schmidt-Nielsen had such diverse feeding habits that uniform procedures could not be applied.

Eight *Aplodontia* and ten rabbits were examined. In general, several *Aplodontia* and rabbits were examined simultaneously. Osmolality of urine and plasma was determined in both species following vasopressin injection during water diuresis according to the method of Dolph *et al.*[7]. Control animals received subcutaneous injection of 1 ml. water.

For a period of at least 13 days prior to any experimental work each animal was given a high or low protein diet. The high-protein diet consisted of pellets containing 15–17 per cent protein and 0·2 per cent sodium. The low-protein diet consisted of lettuce and carrots containing 1·2 per cent protein and 0·0012–0·0031 per cent sodium. Water was given freely with both diets. On a pellet diet the daily protein intake of *Aplodontia* was approximately 7 gm and on a lettuce and carrot diet it was approximately 3·6 gm. Six high-protein-fed *Aplodontia* also received 1 per cent urea in the drinking water *ad libitum* for 36 h prior to any experimental work to ensure a high plasma urea concentration.

The urea-nitrogen and sodium excreted in 24 h were determined from urine samples collected from each animal after it had been fed one or the other diet for at least 13 days. The sodium concentration was determined on a Coleman flame photometer and the urea-nitrogen concentration by colorimetric analysis. No urine urea-nitrogen or sodium concentrations were determined for urea-loaded animals. Prior to any experimental work, plasma urea-nitrogen and sodium concentrations were also determined.

The ratio of urine osmolality to plasma osmolality (U/P ratio) was determined during the vasopressin-injection procedure at the time of maximum urine concentration. Table 1 presents the maximum U/P ratios achieved by *Aplodontia* and the rabbit when fed different diets. *Aplodontia* can concentrate no better when eating a pellet diet ($U/P = 1{\cdot}47$) or urea loaded ($U/P = 1{\cdot}57$) than when eating lettuce and carrots ($U/P = 1{\cdot}48$). However, the rabbit can raise its urine concentration when fed a high-protein diet ($U/P = 3{\cdot}28$) over that achieved when fed a low-protein diet ($U/P = 2{\cdot}59$).

Table 1. Urine and Plasma Osmolality at Time of Peak Urine Concentration following Hydration and Vasopressin Injection

Animals and diet	Plasma (mOsm)	Urine (mOsm)	U/P
A. rufa, *H.P.*†(11)	292	429	1·47
A. rufa, *L.P.*‡ (7)	282	421	1·48

Legend same as for Table 1.

were significantly higher than those obtained from animals on a low-protein diet (7·7 mg/100 ml. and 12·6 mg/100 ml. respectively). The highest plasma urea-nitrogen concentrations (20·5 mg/100 ml.) were from *Aplodontia* fed a high-protein diet and 1 per cent urea in the drinking water. The plasma sodium concentration did not vary with dietary changes in either species.

Aplodontia excreted much more urea per unit of body-weight than did the rabbit regardless of diet. It also excreted more sodium per unit of body-weight when fed a low-protein diet than when fed a high-protein diet, but the rabbit did not demonstrate this difference in sodium excretion. Thus, in *Aplodontia*, sodium excretion increased when urea excretion decreased and vice versa. This interdependence of urea and sodium in producing a concentrated urine was described by Schmidt-Nielsen *et al.*[3] in beaver, pig, and gerbil, and appears to occur in *Aplodontia* but not in the rabbit.

These experiments show that when intake of nitrogen is increased in *Aplodontia* there is no increase in maximum urine concentration following vasopressin injection. The response of *Aplodontia* to a high-protein diet is, therefore, similar to that of the pig, gerbil, and beaver. Increased nitrogen intake in the rabbit, however, results in increased maximum urine concentration.

Because urine-concentrating capacity is dependent on the concentration of the renal medullary interstitial fluid, our results suggest that the absence of looped vasa recta in *Aplodontia* may prevent the efficient trapping of solute such as urea in the medullary interstitium. This is supported by our results, which show higher plasma urea concentrations in the rabbit than in *Aplodontia* with greater urinary excretion of urea in *Aplodontia*.

It would be valuable to know if the pig, beaver, and gerbil lack looped vasa recta, as is known to be the case for *Aplodontia*. We suggest that a comparative examination of vertebrate renal medullary blood supply will be as fruitful as previous comparative examinations of the nephron[8] in explaining certain differences in renal function.

Effects of *d,l*-Aldosterone on Renal Excretion of Water, Sodium, and Potassium induced by Renin

Both renin and oxytocin augment the renal excretion of water, sodium, and potassium in rats. When these substances are injected simultaneously, the increase of diuresis is approximately equal to the sum of the amounts excreted when they are given separately. This effect is the same, even when the dose of renin is large enough to elicit a maximum excretory response within the first 2 h (ref. 1). Besides showing that oxytocin affects the output of electrolytes by a mechanism different from renin, these experiments would appear to support the assumption that oxytocin enhances the elimination of sodium by counteracting the effect of aldosterone. It has been shown that a dose range of 2·5–5 mU of oxytocin neutralizes the sodium-retaining activity of 1 μg of aldosterone[2]. Moreover, recent investigations by Bartter *et al.*[3], Mulrow and Ganong[4], and Kaplan and Bartter[5] have demonstrated that renin, through its ability to release angiotensin, stimulates aldosterone secretion. In view of aldosterone's sodium-retaining potency, it was expected that this hormone would counteract the effect of either renin or oxytocin on sodium excretion. But contrary to the expectation, aldosterone was shown to facilitate the action of renin in the experiments here described.

Four groups of 40 adult female rats of the same weight and submitted to the same conditions were used. On the day of the experiment, after fasting 12 h, they were placed in metabolic cages to collect the urine. In each cage there were four rats with free access to a drinking solution containing 250 mg of sodium and 25 mg of potassium per litre.

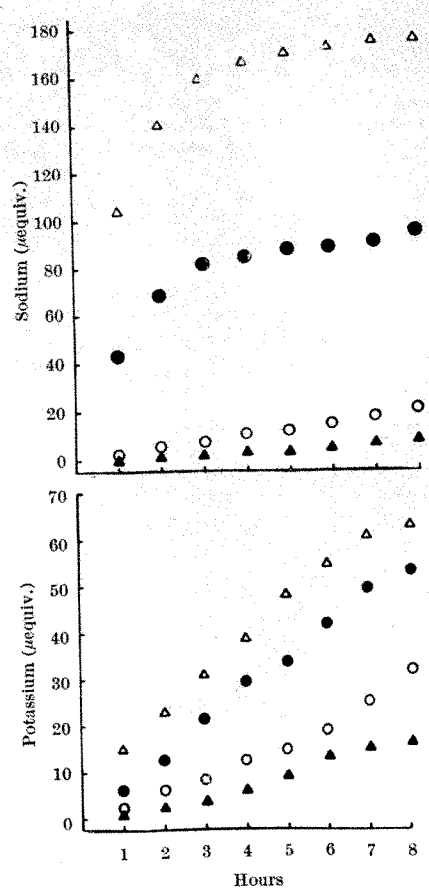

Fig. 1. Excretion of sodium and potassium in μequiv./100 g/body-wt. during 8 h with four groups of 40 rats each: aldosterone group injected with 5 μg aldosterone; renin group with 10 G.U. renin from rat kidney; renin–aldosterone group with 5 μg of aldosterone and 10 G.U. renin; control group with solvent solution. △, Renin–aldosterone; ●, renin; ○, saline; ▲, aldosterone

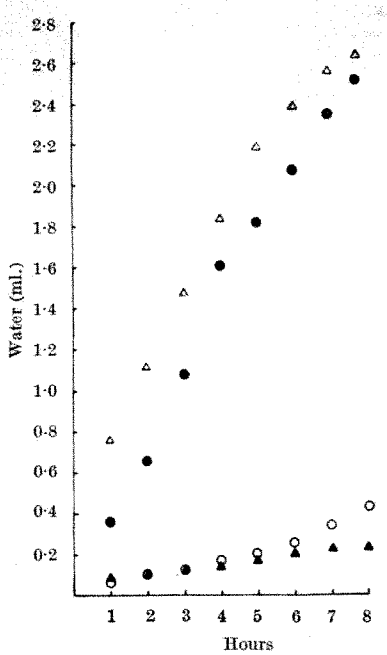

Fig. 2. Excretion of urine in ml./100 g/body-wt. by the four groups of rats indicated in Fig. 1

The first group of 40 rats was injected subcutaneously with 5 μg of aldosterone per 100 g body-weight; the second group received intraperitoneally 10 Goldblatt units (G.U.) per 100 g/body-wt. of renin from rat kidney purified by the method of Braun-Menendez *et al.*[6]; the third received a subcutaneous injection of 5 μg of aldosterone and 10 G.U. of renin; and the control group was injected subcutaneously and intraperitoneally with solvent solution (Tyrode). During 8 h the volume of urine collected in each cage and its sodium and potassium content were measured half-hourly; the Na/K ratio was calculated.

In the first group aldosterone clearly inhibited excretion of sodium throughout the entire experiment (Fig. 1), but the output of potassium was also less than that of the control (Fig. 1). The reduced sodium elimination was reflected in the very low Na/K ratios (0·22) in the third and fourth hours of the experiment.

Renin given with aldosterone to the third group strikingly increased the excretion of water, sodium, and potassium during the first 5 h, but particularly in the first 60 min. The amount of sodium and potassium eliminated at the end of the second hour was approximately twice as much as that excreted by the group given renin alone (Fig. 1). Moreover, excretion of water and electrolytes began much sooner in the renin–aldosterone-injected rats than in the renin group (Fig. 2).

In a second experiment using a different batch of aldosterone the results were very similar.

Obviously the 5 μg dose of aldosterone per 100 g/body-wt. facilitated the characteristic effect of renin by intensifying its influence over the excretion of all the constituents. The Na/K ratios of the renin–aldosterone and renin groups rose to 7·3 and 7·1, respectively, in the first hour and afterwards fell in parallel, while in the control group the ratio was close to unity for the first three hours.

Related experiments utilizing the same renin demonstrated that the intraperitoneal injections of 2·5, 5, and 10 G.U. per 100 g/body-wt. produced adrenal ascorbic acid depletion of 21·5, 34·3, and 49·6 per cent respectively in glands removed 1 h after the injection[7]. Although no direct measurement was made to determine aldosterone content in the blood, activation of the adrenal gland was evident and presumably the diuretic action of renin coincided with increased endogenous secretion of aldosterone.

It remains to be explained how aldosterone, usually an anti-natriuretic factor, facilitates the output of sodium induced by renin. Perhaps the work of Croxatto and Foradori[8] concerning the effect of aldosterone on the intra/extracellular sodium ratio could explain the phenomenon. Under the influence of aldosterone, the intracellular sodium moves out when the intra/extracellular sodium ratio is high. If this were the case, aldosterone could enhance the escape of sodium through the kidney.

It is interesting to note that the injection of angiotensin elicits increased sodium and chloride excretion in hypertensive human beings[9] and that higher aldosterone elimination has been found in severe hypertensive cases[10].

We thank the Gildmeister Foundation for its financial support, and CIBA, Ltd., and Sandoz, Ltd., Basle, for their supply of *d,l*-aldosterone and oxytocin (syntocinon) respectively.

Perfusion of the Viable Sheep Fœtus

The perfusion of the isolated fœtus allows aspects of fœtal metabolism to be investigated in the absence of placental transfer or synthesis of metabolites. A future extension of this technique may find application in the management and treatment of the premature or hypoxic human infant.

A simple technique has been developed for the perfusion of the sheep fœtus, and an attempt has been made to validate the method by perfusing animals of a viable age and allowing them to survive after the perfusion. Three such experiments have been carried out and in each case the animal showed normal behaviour for the following 24 h. Although techniques for fœtal perfusion have been described previously (human[1], pig[2] and sheep[3]), only recently, while this investigation was in progress, has survival after perfusion been reported[4].

Three ewes bearing fœtuses of a viable age (over about 140 days' gestation) were anæsthetized under procaine spinal anæsthesia, supplemented with intravenous thiopentone to maintain light general anæsthesia. After withdrawing between 150–200 ml. of blood from the dorsalis pedis artery to prime the perfusion circuit the fœtuses were exposed by Caesarean section. The fœtal head was enclosed in a bag of 0·9 per cent sodium chloride to prevent the onset of breathing. Following a local subcutaneous injection of procaine the fœtal femoral artery was catheterized for blood pressure determinations and the subsequent removal of blood samples. The umbilical vessels were prepared for cannulation under the

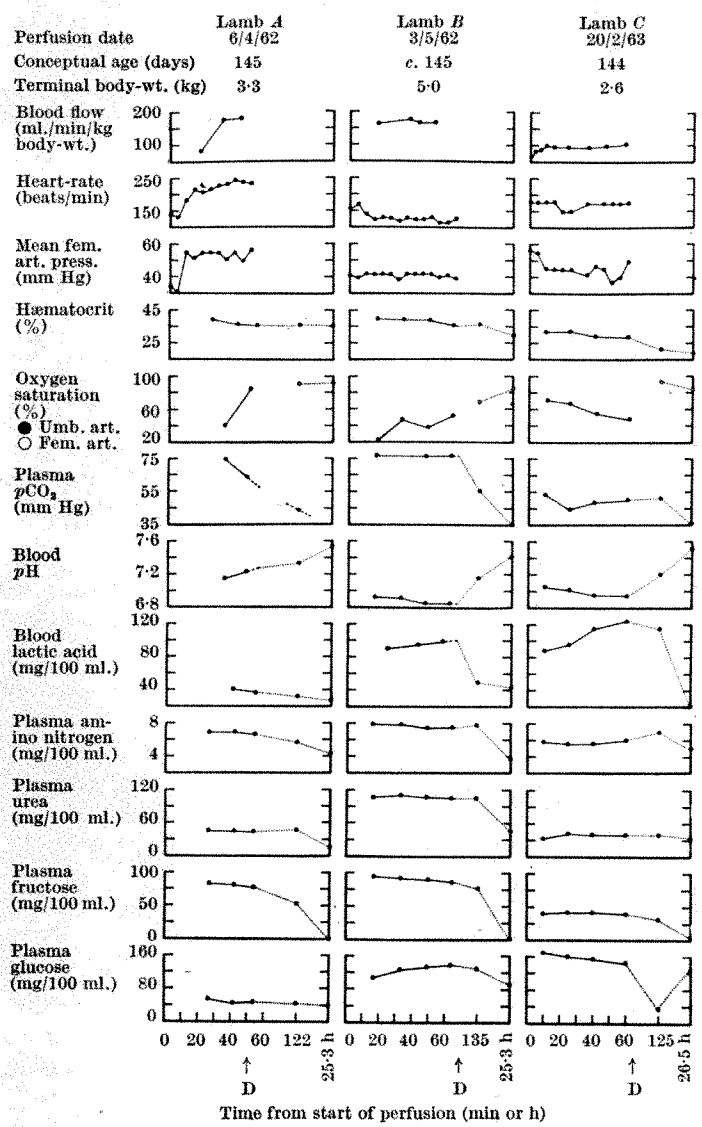

Fig. 1. Data obtained from the lambs during perfusion (●——●) and after perfusion (●·····●) plotted against time from the start of perfusion. Detachment from the perfusion circuit took place at *D*

local application of formol–saline. After injecting 50 mg heparin into an umbilical vein an arterio-venous anastomosis was established in one of the two pairs of arteries and veins of the umbilical cord. The remaining artery and vein were then cannulated and the umbilical cord cut. The latter vessels were connected to the perfusion circuit which had been primed with heparinized maternal blood, and finally the umbilical arterio-venous anastomosis was severed and its connexions incorporated into the circuit. The perfusate volume was approximately 150 ml. The function of the anastomosis was to maintain the cardiac output by ensuring that at no time was there stasis of flow of blood in the fœtal-umbilical circulation. Preliminary experiments had shown that such an anastomosis was well tolerated by the fœtus.

In the perfusion circuit blood was pumped by the fœtal heart along the cannulated umbilical arteries into a spinning disk oxygenator through which passed a warm-moist 97 per cent oxygen + 3 per cent carbon dioxide gas mixture. The outflow into the oxygenator was controlled either by a screw clip or by altering the height of the oxygenator with respect to the level of the fœtal heart. Oxygenated blood accumulated in a reservoir below the oxygenator from which a variable speed rotary pump conveyed the blood through a filter to the umbilical vein. The animal, wrapped in polythene sheeting and cotton wool, lay on an electric blanket; the oxygenator was wrapped with an electric heating mantle and the rest of the perfusion circuit lagged to prevent heat loss. The inflowing blood temperature lay between 34·5° and 37° C. The speed of the pump was adjusted manually such that the volume of blood in the fœtus, as judged by the level in the reservoir, remained constant. Blood flow was computed from knowledge of the output per turn of pump and the number of turns per minute.

Perfusion was allowed to proceed for about 60 min; during this period, samples of blood were removed from the circuit for analysis. Occasional limb and abdomino-thoracic movements were made by the fœtus. The bag covering the fœtal head was then removed and the umbilical cord stretched and tied. The animal was dried and stimulated generally by rough towelling. The catheter in the femoral artery was bandaged against the thigh and blood was removed for analysis approximately 1 and 24 h after detachment from the perfusion circuit.

The changes in concentration of various blood components during and after perfusion in the three lambs are shown in Fig. 1.

The heart-rate, femoral arterial pressure, blood flow and umbilical arterial oxygen saturation, although variable, were of the same order as those encountered by other workers[5,6]. The hæmatocrit values remained fairly steady, falling in the post-perfusion period in lambs *B* and *C*. The very low value found in lamb *C* is probably due to fluid transfer associated with a hæmorrhage sustained prior to the start of the perfusion.

Considerable differences in the concentration of plasma constituents were observed in the three animals during the perfusion period; nevertheless, these did not appear to affect the well-being of the animal in the post-perfusion period. Thus in lambs *B* and *C* the blood lactic acid was very high and was associated with acidotic *p*H values. The high lactic acid concentrations may have been due, at least in part, to hypoxia before attachment to the circuit; they were not general in perfusions of younger fœtuses, which will be reported later. The plasma partial pressure of carbon dioxide was high in lambs *A* and *B* but fell to normal values in the post-perfusion period. These variations in plasma pCO_2 illustrate the difficulty in constructing a suitable oxygenator of low priming volume. The concentration of α-amino nitrogen and urea in the plasma remained steady during the perfusion but declined in the post-perfusion period. Hyperglycæmia (for the sheep) was present in lambs *B* and *C*. In all lambs the fructose concentration was seen to fall to zero within 24 h of their detachment from the placental site of synthesis[7]. This decline can be attributed to urinary loss[8,9].

Within 3 h of tying the umbilical cord all the lambs were capable of standing voluntarily. They were placed in a pen at room temperature and maintained on a 3–4 h bottle-feeding regimen with cow's milk. After some 24 h the animals were killed by intraperitoneal 'Nembutal'. At post-mortem no macroscopic changes were observed. The behaviour of the animals observed in the post-perfusion period, for example, suckling, walking, bleating, response to noise and light, interest in environment, etc., appeared to be unaffected by the perfusion as judged by our previous experience with non-perfused premature lambs[10]; and this was also clearly seen in lamb *C*, the twin of which, subsequent to the termination of perfusion, was removed by Caesarean section and maintained in the same pen.

Application of the Arrhenius Equation to Rat Tail Tendon Collagen

An important and widely investigated property of collagen is its hydrothermal shrinkage. The concept of shrinkage temperature (T_s) has been developed as a manner of characterization of the hydrothermal stability of the fibre. Shrinkage temperature is determined by heating the fibre in water, the temperature of which is increased at the rate of 2 deg./min. The fibre is kept under observation, and the temperature at which contraction occurs is noted as the T_s of the fibre in question. Usually a range of temperature is recorded because the end point of reaction is not precise. Although useful, the concept of T_s is not a strictly valid one. Shrinkage curves constructed from data on length of fibres plotted against time at various temperatures clearly establish that the process of shrinkage of collagen is a rate phenomenon and that a true shrinkage temperature does not exist from a thermodynamic point of view. For this reason, Weir and Carter[1,2] examined the hydrothermal stability of collagen as a rate process. They stated that the reaction appeared to be of the first order and applied the theory of absolute reaction rates to the process. The half-time of the fibre shrinkage was taken as an index of the reaction rate at each of several temperatures and these $t_{1/2}$ values were substituted for rate constants in the Arrhenius equation.

ΔH, the heat of activation, was substituted for ΔE, the energy of activation in the equation, since ΔH is within 1 kcal/mole of being numerically equal to ΔE. A graph of log $0{\cdot}6932h/kTt_{1/2}$ against $1/T$, where k is Boltzmann's constant, h is Planck's constant, T is the absolute temperature and $t_{1/2}$ is the half-time of collagen shrinkage, yields a line that has a slope and intercept proportional to ΔH and ΔS respectively. In this manner, it was possible to determine values of ΔH and ΔS for kangaroo tail tendon and from the relationship of $\Delta F = \Delta H - T\Delta S$ to determine ΔF. Weir used this method to describe in thermodynamic terms the changes which occur in collagen as a result of the tanning of collagen by various chemicals, such as formaldehyde and non-ionic chromium complexes.

Surprisingly, although hydrothermal shrinkage of rat tail tendon has been investigated from many points of view, Weir's conception of the reaction as a temperature-dependent rate process has not been used in any of the investigations so far described. Kohn and Rollerson[3], using human diaphragm tendon, attempted to produce an Arrhenius plot at elevated temperatures but stated that the results were not sufficiently accurate to produce a linear relationship.

If such a plot could be satisfactorily produced for rat tail tendon collagen, a valuable tool would be made available for the examination of various pathological problems in which alterations of connective tissue become manifest. The values of ΔF, ΔH and ΔS could be compared in control and experimental animals, and if changes are noted these could be further compared with the reaction of the fibres in other situations such as ageing or cross-linking by exposure of collagen to physiologically occurring aldehydes.

The work reported here was undertaken to determine whether Weir and Carter's formulation could be applied to rat tail tendon collagen. This collagen was taken from Long–Evans strain rats of 60 ± 2 days of age. Collagen fibres removed from the tails were placed in distilled water in an ice bath and were divided into five groups of tendons about 10 cm long and 0·15 mm in diameter. These tendons were weighed before use in order to ensure uniformity of the group. The tendons were allowed to stand in distilled water at 4° C overnight and the following day shrinkage rates were determined in a test-tube in distilled water using a full visibility water bath at step-wise temperature gradients between 63°–67° C. A 50-mg lead weight was suspended from the end of the collagen fibre to keep slight tension on the tendon so that it should not coil, and its upper extremity was held in a slit rubber stopper. Especially prepared test-tubes graduated in 1-mm steps were used for determining length of the collagen fibre and time elapsed was determined by a direct-reading timer which was graduated in 0·01 min. Values of $t_{1/2}$ were obtained by interpolating the time corresponding to the fibre-length given by the equation $(l_0 + l_c)/2$, where l_0 is the original length and l_c is the fully contracted length.

Although there is some scatter of the $t_{1/2}$ values at any given temperature, the group means of six determinations (expressed in terms of log $0{\cdot}6932h/kTt_{1/2}$) at each of five temperatures usually produce linear relationship when plotted against the reciprocal of the absolute temperature. The best line through the 30 points was determined by the method of least squares and the slope and intercept were used to calculate the heat of activation, ΔH, and the entropy of activation, ΔS. From these values, the free energy of activation at 60° C, ΔF_{60}, was calculated as already described.

The linearity of the regression line was tested by comparing the variance within groups with the variance of the deviations of the group means from the estimated regression line. By this test, linearity was not rejected in 10 of the 13 animals examined. Table 1 gives the values found. The values calculated in the statistically non-linear group are not included, but all values in those animals were within two standard deviations of the values in Table 1.

Weir and Carter were of the opinion that the regression line constructed in this manner could be used to calculate a shrinkage temperature which would be of more significance than the T_s as ordinarily determined. The temperature at which half-shrinkage occurs in 1 min for any animal is noted in Table 1.

Table 1. Eight to Nine Week Age-group (60 ± 2 Days)

Animal	ΔH (kcal/mole)	ΔS (cal/mole deg.)	ΔF_{60} (kcal/mole)	T_s (1 min)	$Sy{\cdot}x$*
2 *BH*	81·597	174·90	23·328	63·3	0·093

Sum	897·814	1,994·80	233·228	630·1	
Average	89·781	199·48	23·323	63·0	
Standard deviation	7·08	21·1	0·139	0·493	

* Standard error of the estimate: The mean deviation of the thirty points of the plot of log $0{\cdot}6932h/kTt_{1/2}$ against $1/T$ from the estimated regression line.

Average values for activation constants of kangaroo tail tendon given by Weir are as follows: ΔH: 141 kcal/mole, *S.D.*, 15; ΔS: 349 cal/mole deg., *S.D.*, 43; and ΔF_{60}: 24·7 kcal/mole, *S.D.*, 0·6. The results given in Table 1 are lower than those given by Weir for kangaroo tail tendon. Preliminary investigations in this laboratory suggest that older animals give higher values for these activation constants than 60-day-old animals, which may indicate these values are dependent on age. The results for rat tail tendon of young rats are, however, clearly of the same order of magnitude as described for kangaroo tendon.

The extrapolation of rat tail tendon data to other mammalian collagen has been criticized by Klein and Curtis[4] because of greater solubility of rat tail tendon collagen than most other mammalian collagen in cold distilled water, dilute acetic acid, and following heat treatment in water at 60° C. While rat tail tendon collagen may have unique properties, it continues to be an extremely useful tool in researches on various aspects of the reactivity of collagen.

The preliminary results described here suggest that this technique may be of value in providing another parameter for comparison of rat tail tendon collagen with other mammalian collagen and may be of value in investigations of processes such as ageing of collagen and changes of collagen in various pathological states in the rat.

Differences between Cortical Recruiting Responses observed during Wakefulness and Natural Sleep

In 1942, Morison and Dempsey[1] demonstrated that low-frequency stimulation (8–12 c/s) of the intralaminar thalamic nuclei of the anæsthetized cat diffusely evoked recruiting responses on the cerebral cortex. These long-latency, large surface-negative responses are distributed widely over the hemispheres and reach their maximal size after repetitive shocks. Long-continued stimulation at appropriate frequencies leads to a periodic waxing and waning of these potentials.

The intravenous administration of 5–20 mg/kg of either thiopental or pentobarbital can enhance the amplitude of recruiting responses and lower their thresholds[2]. Further, since stimulation of the brain stem reticular formation prevented their occurrence[3], it was assumed that recruiting responses could not be obtained in the unanæsthetized, non-immobilized animal. However, Evarts and Magoun[4] have demonstrated that stimulation of the intralaminar nuclei may evoke recruiting responses in normally awake animals. The relationship between the characteristics of recruiting responses and the various levels of consciousness still remains to be determined.

In the present investigation, low-frequency stimuli were delivered to non-specific thalamic system during the transition from wakefulness to sleep in 5 unanæsthetized and unrestrained cats with chronically implanted electrodes. The stimulating electrodes were implanted either into the n. centralis lateralis (CL), the n. centralis medialis (NCM) or n. centrum medianum (CM). Recording electrodes were placed on the cranial dura mater and into the dorsal hippocampus (DHIPP), and the mesencephalic reticular formation (MRF). EKG and EMG (neck muscles) were recorded simultaneously.

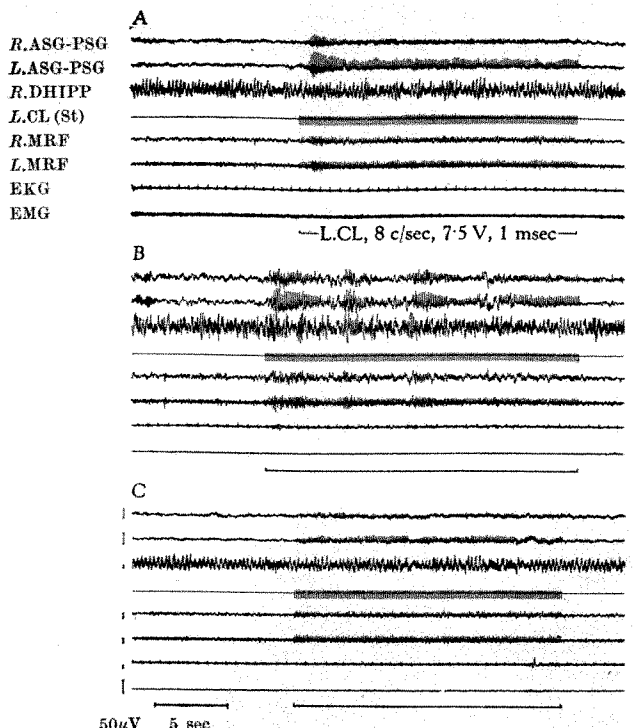

Fig. 1. Recruiting responses observed in the same animal following low-frequency electrical stimulation (8 c/s, 7·5 V, 1 msec pulse) of the left CL during wakefulness (*A*), slow-wave sleep stage (*B*) and fast-wave sleep stage (*C*). *B* recorded 20 min after *A* and *C* recorded 30 min after *B*. In all figures, recordings are bipolar. *R*, right; *L*, left; ASG, anterior sigmoid gyrus; PSG, posterior sigmoid gyrus; St, stimulating electrode

During wakefulness, stimulation was begun only when rapid low-voltage electrocortical activity and hippocampal rhythmic theta waves were present. In such instances recruiting responses were induced by 8-c/s stimulation of the non-specific thalamic nuclei (for example, stimulation of left CL, Fig. 1*A*). If the animal became attentive or moved, these recruiting responses were depressed.

If the animal spontaneously became more drowsy and entered the slow-wave stage of sleep successive thalamic stimulations produced clear-cut recruiting responses characterized by unmistakable waxing and waning of potentials (Fig. 1*B*). At the same time heart rate, respiratory rate and amplitude of EMG were decreased. In the intervals between stimulations both high-voltage slow-waves and sleep spindles are prominent.

After a prolonged period (usually more than one hour) of complete isolation in a sound-proofed environment, low-voltage fast cortical activity, hippocampal rhythmic theta waves, absence of EMG activity of the neck muscles, increased respiratory rate and sporadic twitching movements of the paws, ears, tail and vibrissæ are observed simultaneously in the sleeping animal. This fast-wave sleep stage has also been described as activated sleep[5], rhombencephalic sleep[6] or deep sleep[7]. Recruiting response elicited under these conditions following identical thalamic stimulations were of lower amplitudes and did not exhibit clear-cut waxing and waning of potentials (Fig. 1*C*).

Although the EEG pattern of the fast-wave sleep stage is similar to that of the awake, alert animal, dissimilar recruiting responses are elicited in these two circumstances. It has been reported that the arousal threshold for reticular stimulation increases during the fast-wave sleep stage[8,9]. Anæsthetic doses of barbiturates also increase this threshold, but at the same time they also enhance recruiting responses[2].

The phenomenon of the recruiting response has been regarded as synchronization of activity of the diffuse thalamic projection system[10]. It is suggested that depression of the mechanisms responsible for inducing

the recruiting response may be greater during the fast-wave sleep stage than during wakefulness or the stage of sleep associated with high-voltage, slow-wave electrocortical activity.

HÆMATOLOGY

Antihæmophilic Globulin in Frozen Plasma

IN a recent communication[1], I described the effect of certain conditions on the stability of freeze-dried factor VIII (antihæmophilic globulin). Owing to the antigenicity of animal material and the restricted supply of human factor[2], other sources of this labile factor have been sought. Plasma, kept frozen after being separated from fresh blood, is now being widely utilized in the management of hæmophilia. This raises for consideration the effect of different methods of freezing on factor VIII and other blood-clotting factors.

Plasmas collected by the same person on the same day showed unequal loss of factor VIII activity after being stored in a deep freeze at −30° C for 48 h. In some cases this amounted to 50 per cent. The following two conditions were thought to contribute to this unexpected finding.

(1) *Variations in the composition of plasma.* These arise mainly from differences in: (*a*) the concentrations of protein, lipoids, minerals, etc., in the donor's plasma; (*b*) the packed cell volumes; (*c*) the ratio of acid-citrate-dextrose solution to the amount of blood collected in each bottle.

(2) *Rate and uniformity of cooling and thawing.* The rate of freezing varied according to whether the M.R.C. bottle was surrounded by air or liquid (Table 1). Frozen plasma (400 ml.) thawed in 4–4½ h at room temperature (18°–20° C). Under running tap-water (18° C), thawing occurred in 1 h. This was shortened to 30 min in a thermostatically controlled water-bath at 37° C. On lowering the temperature, the composition of a solid–liquid system changes by the deposition of solid(s). The separation of solid is accompanied by the evolution of heat which diminishes the rate of cooling. The temperature remains constant until the system is completely solid whereupon cooling proceeds further. The reverse occurs during thawing. These changes may lead to the development of *p*H, salt concentrations or other conditions which, depending on the temperature and the period (reduced by freezing and thawing in liquid, as mentioned here) during which they operate, adversely affect the blood-clotting factors. Some of these changes are given in Table 2.

Table 1. TIME REQUIRED FOR FREEZING 400 ML. PLASMA IN M.R.C. BOTTLE

Temperature (° C)	Surrounding medium: Air	Liquid
	Freezing time (min)*	
−20	180–240	60–70
−30	150–200	45–55
−40	150–170	30–40
−65	—	8–10†

* Complete solidification of contents. Longer periods are required for the contents to reach a homogeneous temperature equal to that of the surrounding medium.
† In order to avoid breakage of bottle, contents were mixed by rotating the bottle in the freezing liquid. In all other instances the bottle was not handled (usual procedure for freezing plasma in deep freeze in blood banks).

Table 2. LOCAL VARIATIONS IN PLASMA COMPOSITION DURING THAWING

Test	Sample* 1	2	3	4 (control)
*p*H	6·75	6·72	6·69	6·70
Total protein (g/100 ml.)	9·8	4·6	2·5	7·2
Blood-clotting factors (% of normal) †:				
Factor II, V	150	70	45	100
VII	150	80	45	110
VIII	120	45	8	80
IX	160	65	35	95
X	150	75	40	100
XII	170	80	40	100

* Freshly collected plasma frozen in a deep freeze at −30° C for 24 h. Liquid samples were obtained at intervals without mixing contents. The control (sample 4), however, was obtained after complete thawing and mixing of contents.
† For 100 per cent standard, fresh plasmas (collected in A.C.D. mixture) from 5 normal subjects were pooled.

That the foregoing two conditions affect the stability of factor VIII in frozen plasma was deduced from the consistency achieved and the negligible loss occurring on rapid pre-freezing of plasma in liquid and thawing in a bath at 37° C.

The effect of storage for longer periods was also investigated. At −30° C factor VIII activity showed 20 per cent and 50 per cent loss after 3 and 6 months respectively. Preservation at −40° C reduced this by approximately 20 per cent. Plasma factor IX activity, as measured by the thromboplastin generation test, was similarly affected. On the other hand factor IX, evolved after coagulation[3], was comparatively stable, less than 10 per cent being lost after 6 months at −30° C. Repeated thawing and re-freezing caused marked reduction in the activity of plasma factors V, VIII and IX, but had no significant effect on other blood-clotting factors. The latter were also highly stable at −30° C.

It would now appear that for maximal activity of factor VIII, fresh plasma should be pooled, rapidly frozen in liquid, and stored at −30° C or at −40° C for a period not exceeding 3 and 4 months respectively. Thawing with continuous mixing of contents at 37° C is desirable. Re-freezing of thawed material should be avoided.

Oxidation of Reduced Glutathione by Acetylphenylhydrazine, Hæmoglobin and Erythrocytes

INCUBATION of erythrocytes, from individuals having the sex-linked, inherited deficiency of glucose-6-phosphate dehydrogenase, with oxidant drugs such as acetylphenylhydrazine (APH) produces a drop in the level of intracellular reduced glutathione (GSH)[1]. Beutler *et al.*[2] consider that APH itself has no effect, but modifies cell hæmoglobin to a complex, not methæmoglobin, which oxidizes GSH. Allen and Jandl[3], on the other hand, have indicated that these two compounds oxidize one another, and that the APH oxidation products aid GSH oxidation.

This communication describes the effects of APH, hæmoglobin and red cells on GSH in air and nitrogen. Heparinized human blood was centrifuged, the red cells washed in 0·9 per cent sodium chloride and used to prepare saline suspensions, 0·1 per cent saponin hæmolysates and

Table 1. Effects of APH, Hæmoglobin, Hæmolysates and Intact Erythrocytes on GSH-Levels

Flasks containing 50 mM potassium phosphate buffer, *p*H 7·4, mM APH and hæmoglobin (Hb) as indicated were pre-incubated for 3 h at 37° C with shaking (Exp. *B*), then incubated 30 min at 37° C with mM GSH (Exps. *A* and *B*). Flasks incubated with nitrogen were flushed for 5 min with the gas at 0° C prior to incubation and stoppered. 1 ml. aliquots were deproteinized with 1 ml. 10 per cent trichloroacetic acid, the supernatants filtered after centrifuging and assayed for GSH[4].

hæmoglobin solutions from hæmoglobin crystals[4]. All preparations were adjusted to mM hæmoglobin concentration.

Experimental details and results are given in Table 1. APH under nitrogen had little effect on GSH but in air some GSH was oxidized, even in the presence of 'Versene' (contrary to Allen and Jandl's[3] findings). The effect was markedly increased in the presence of hæmoglobin, indicating some interaction between APH and hæmoglobin to form an oxidant. There was no evidence for an additional cellular GSH-oxidizing mechanism other than hæmoglobin, such as glutathione peroxidase[5]. In fact, hæmoglobin had a stronger oxidant action than hæmolysates or intact red cells, possibly due to the presence of oxidizable substances in the latter. Hæmoglobin itself could oxidize GSH to some extent, the degree of oxidation increasing as the hæmoglobin concentration was raised from 0·2 to 1·0 mM; this effect was greatly enhanced if APH was also present. If APH in buffer was oxidized by pre-incubation in air, its ability to oxidize GSH on subsequent incubation was much greater and independent of the presence of hæmoglobin. However, while the yellow-coloured oxidation products of APH in air were dialysable, the products of interaction of APH with hæmoglobin in air were not. This may be due to the attachment of APH oxidation products to the protein molecule. On addition of trichloroacetic acid to the dialysed APH–hæmoglobin complex, the typical yellow colour of APH oxidation products was obtained in the supernatant. The hæmoglobin itself was partially oxidized to methæmoglobin under these conditions, since the methæmoglobin content increased from 8 per cent (present in freshly prepared solutions) to 23 per cent after 3 h incubation in air with APH.

These results, while indicating the formation of an APH-modified hæmoglobin[2], also confirm that APH oxidation products oxidize GSH. No evidence was obtained for the existence of a cellular GSH-oxidizing mechanism other than hæmoglobin.

PATHOLOGY

Infiltration of Intra-abdominal Organs by Ascites Tumours

The ability of tumour tissue to invade 'normal' tissues, to enter circulatory systems of the body and to grow at sites near and distant from the primary source is one of the basic characteristics of malignant growth. However, this property is not diagnostic, for certain non-malignant (normal) tissues can permeate other normal tissues, for example, trophoblasts, macrophages, polymorphonuclear leucocytes. These invasive cell types are under the control of the body and although they may be actively destroying host tissues at times, their service to the organism is strictly regulated and made beneficial ultimately while malignant neoplasms are destructive ultimately. The capacity to infiltrate may be associated with behaviouristic changes in cells of tumours, shown *in vitro* (loss of contact inhibition)[1], changes in the surface properties[2] and possibly with enzymatic activity[3]. However, it is desirable to be able to study invasiveness of neoplastic tissue *in vivo*.

There have been several reports of the invasiveness of ascites tumours[4–6], reports of the infiltrative properties of ascites tumours following injury[7] and of solid tumour infiltration due to mechanical injury[8]. It appears that: (1) certain organs may be infiltrated more rapidly than others; (2) various treatments of the peritoneal surface render it more liable to be infiltrated. The work described here is concerned with ascites tumours since these transplantable tumours provide a reasonably reproducible system of cell invasion where tumour mass can be assessed easily and accurately. With this system it is possible to examine the relationship between tumour growth and the commencement of tumour cell infiltration and also the role of factors other than tumour growth in infiltration.

The rates of infiltration into eleven different regions of the abdominal viscera and peritoneum were found by inoculating 20 × 10^6 Ehrlich's ascites carcinoma cells into female *BALB/c* mice. The amount of tumour was estimated by total free cell counts after killing the animals (Table 1).

It is evident that host response, adhesion and infiltration of tumour cells go hand-in-hand, although in the case of the mesenteries only the thickest regions show host defence cells present along with adhering tumour cells. Tumour cells appear to adhere virtually all over the mesenteries within a very short time. The duodenum, uterus, ovary, kidney, liver and spleen appear to have almost entirely refractory capsules. At the very last stages of tumour development prior to host death (about 20 days after injection of tumour), there are still no tumour cells attached to the duodenum; the liver may have one or two clumps of tumour cells adhering to a very vascularized periphery and likewise the spleen.

The body wall has been studied most carefully. When tumour development has reached a total free ascites cell count of 400–500 × 10^6 cells, host response is seen by the infiltration of lymphocytes and leucocytes near the peritoneal mesothelium. The submesothelial region

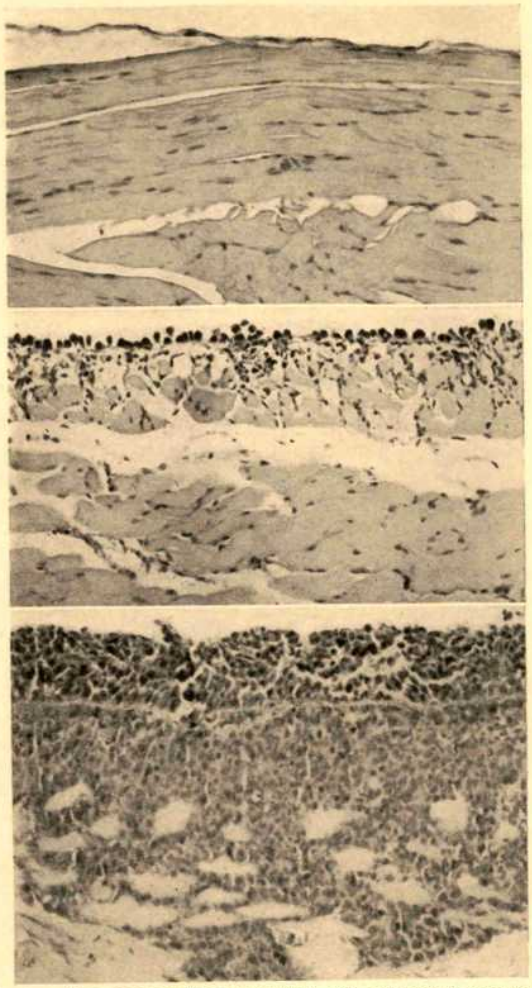

Fig. 1. Top, body-wall musculature and peritoneal mesothelium (detached at left) of normal animal and up to six days after intraperitoneal injection of 20 × 10^6 Ehrlich's ascites cells. Middle, layer of tumour cells adhering to the peritoneal mesothelium or subserosa. Eight days after tumour injection. Note œdema, vascularization and presence of host defence cells. Infiltration just beginning. Bottom, heavy invasion of ascites cells forming solid tumour around the body-wall musculature; 21 days after injection of tumour. Note the presence of delineation between peritoneal cavity and body wall

enlarges with apparent proliferation of the connective tissues, and also with œdema. The peritoneal mesothelium itself is hypertrophied. These changes occur very suddenly, not being evident on the 6th day (300–420 × 10^6 tumour cells) in light microscopic examination of histological sections, evident on the 7th day (400–660 × 10^6 cells) and pronounced with adhesions and infiltration of tumour cells after the 8th day (to 1,000 × 10^6 cells) (see Fig. 1).

The adhesions of tumour cells have been confirmed by electron microscopical and histochemical studies. Previously the difficulty had been to distinguish hypertrophied mesothelial cells from tumour cells in the light microscope. The electron microscopical study of this process of cell infiltration has confirmed the light microscope observations of the changes occurring in the subserosal connective tissue and has shown that the mesothelium is sometimes removed where tumour cells are adhering.

The presence of infiltrated tumour cells below the peritoneal mesothelium has been confirmed by subcutaneous implantation of pieces of body wall stripped of the peritoneal mesothelium from nine-day ascites tumour-bearing mice. The grafts grew up into typically subcutaneous Ehrlich carcinomata in the majority of hosts.

The same pattern of adhesion and infiltration has been demonstrated in other ascites tumours (Landschütz ascites in *BALB/c* mice, *MClM*, M_{AA} in *C3Ha* mice, Krebs's in *CBA/H* and *NK/Ly* in *C3H* mice).

The *MClM*,M_{AA} tumour became very hæmorrhagic during the course of transplantation into different strains of mice (though closely related strains). This hæmorrhagic nature has been correlated with the natural resistance of the host to the tumour[9]. It was found that development of the tumour was slower when the tumour induced hæmorrhage than when it was non-hæmorrhagic, but there was a stronger host reaction developing earlier after an inoculation of 20 × 10^6 tumour cells. Adhesions of tumour cells occurred earlier in hæmorrhagic tumours and infiltration began about the eighth day (as for non-hæmorrhagic tumours) when the total free cell count was about 200 × 10^6 cells. This is only about a third of the total tumour cell count in the non-hæmorrhagic tumours when infiltration begins.

The adhesion of ascites tumour cells to the peritoneum and their subsequent infiltration can be enhanced by injecting mechanical irritants into the peritoneum. When kieselguhr was injected in small doses intraperitoneally ascites tumour cells adhered to the peritoneum at points of injury within a short time (evident in sections taken at 1 day after inoculation). With larger doses of kieselguhr a more general adhesion of tumour cells was apparent with less localization at points where kieselguhr was actually wounding the mesothelium. This treatment of the peritoneum enhancing implantation of tumour tissue was shown in 1914 by Jones and Rous[8], who used fragments of solid tumours.

In conclusion, it has been shown that certain regions of the viscera are infiltrated earlier than others and infiltration seems to follow the development of host response to the tumour. Although ascites tumour cells may possess the surface characteristics and motility to enable them to invade, this process can only occur in the rather refractory tissues of the body wall[8] after the initiation of this host response. By altering the nature of the peritoneal surface and sub-mesothelial connective tissue[10] by immunological, chemical and mechanical means, it is possible to enhance the infiltration of tumours. Our more recent experiments have suggested the importance of the role of the immunological responses in the invasiveness of tumours in that, within certain limits, the early stages of invasion would appear to be facilitated by an increase in the immune responses of the host and retarded by a decreased response. These experiments will be reported later.

We thank Prof. Alexander Haddow for his interest in this work. We also thank Mr. E. Woollard for helping with the histology, Mr. M. S. C. Birbeck for the electron microscopy and Prof. L. Wattenberg for some histochemical work. This investigation was supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the Medical Research Council, the British Empire Cancer Campaign, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

Induction of Tumours of the Stomach in Rats and Mice by *N*-nitroso-*N*-alkylurethanes

The induction of squamous carcinoma of the stomach and of the œsophagus in the rat by *N*-nitroso-*N*-methylurethane (NMU)[1] and by some other nitrosamines[2] has been reported. Squamous tumours of the stomach have been known to develop following treatment with various other carcinogens; but very few instances have been reported of the induction of tumours of the glandular part of the stomach in rodents. Such tumours have usually been produced by direct intramural injection of carcinogenic polycyclic aromatic hydrocarbons[3]. One adenocarcinoma resulted after administration of 4-nitroquinoline-*N*-oxide through a stomach fistula to 16 rats which had in addition percutaneous applications of 20-methylcholanthrene[4]. Recently, Stewart *et al.*[5] induced adenocarcinomata of the glandular stomach in four out of 47 rats, given 2,7-*bis*(acetamido)fluorene in diet.

It is therefore of interest that in the course of further experiments using NMU under conditions similar to those described previously[1] a rat, which survived 2 years after the first of two oral doses (2·5 mg per dose, at 1-month interval), was found to have a large papillary growth on the glandular part, projecting into the lumen of the stomach (Fig. 1). The squamous part was very small, and the duodenum greatly distended. Microscopically, this lesion had characteristics similar to those described as adenocarcinoma by Baba *et al.*[4]; but no definite evidence of invasiveness was seen in the section. Other animals of the same series had squamous carcinomata, sometimes accompanied by foci of hyperplasia in the glandular part of the stomach. Various degrees of hyperplasia of the glandular part of the stomach have been noted already among rats in the previous series[1].

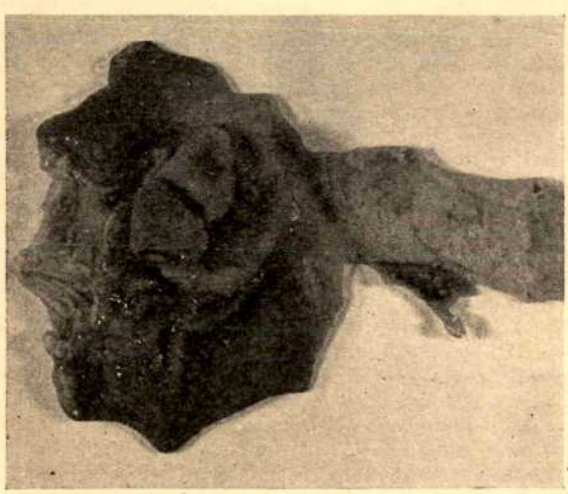

Fig. 1. Stomach and duodenum of a female rat which was given two doses of *N*-nitroso-*N*-methylurethane by stomach tube (2·5 mg per dose at 1-month interval). Killed 2 years after the first dose. Note the small size of the stomach, especially of its squamous part, the distended duodenum and the large papillary growth in the middle of the glandular part (× *c.* 1·3)

In view of the striking carcinogenic properties of NMU it was of interest to test its homologue, *N*-nitroso-*N*-ethylurethane (NEU). Among seven male white mice which survived 11–13 months after the first of four oral doses of NEU (1–2 mg per dose in aqueous ethanol, given in the course of nine months), three developed squamous carcinomata, one had in addition a sarcoma and one mouse had a papillary growth, with features suggestive of neoplasia, on the glandular part of the stomach, but again no evidence of invasion was seen.

Thus NEU induces in mice stomach tumours and lesions similar to those seen in rats given NMU. The type of tumour and the site of its appearance may depend on the site of the deposition of the *N*-nitroso-*N*-alkylurethane from the stomach tube. This can be introduced deep into the glandular part, or only as far as the squamous part of the stomach or the œsophagus. Thus, even a slight variation in the conditions of administration may determine the type and the site of tumours induced by nitroso-alkylurethanes. Like NMU[6], NEU undergoes decomposition with evolution of nitrogen in contact with —SH containing compounds or tissues, at neutral *p*H.

The induction of proliferative lesions of the glandular part of the stomach of mice and rats by these *N*-nitroso-*N*-alkylurethanes is of particular interest, and suggests that in time unequivocally malignant tumours might develop among the surviving animals.

I thank Dr. P. N. Magee for the microscopic evaluation of the lesions.

Note added in proof. Since this communication was submitted an undoubtedly malignant adenocarcinoma of the glandular stomach, with local spread, was found in a rat treated with NMU.

Pinealoma : a Variety of Argentaffinoma?

Serotonin (5-hydroxytryptamine) contained in the gastrointestinal tract is intimately associated with the Kultschitzky type of cells[1]. Carcinoid tumours arise from such cells so their serotonin content is very important[2]; apparently, the majority, or maybe all, the symptoms of the so-called carcinoid syndrome must be attributed to the presence of serotonin at the level of the tumour[3].

Histochemically, the serotonin contained in Kultschitzky cells and in carcinoid tumours may be demonstrated as intracytoplasmic granules intensely argentaffin and faintly positive or negative to chromaffin reaction[4].

The parenchymal cells of pinealoma (Fig. 1) behave as Kultschitzky cells and carcinoid cells; thus, they reduce silver ammoniacal solutions and do not show affinity for chromium salts. For that reason it is possible that they also contain serotonin. This substance is very abundant in the nervous tissue of the brain, especially at the level of the basal nuclei, close to the pineal body. Here, serotonin could be secreted, stored or eliminated by the brain[5].

We do not know of any reference relating serotonin to either pineal body or pinealomata, nor any which refers to a clinical syndrome comparable with the carcinoid tumour in pinealoma. Since this syndrome was not discussed until 1956, it is possible that it has not been noticed in patients with pinealoma either; on the other hand, only in malignant carcinoids having hepatic metastases has this syndrome been demonstrated, and no cases of metastatic pinealoma are so far known.

Pinealoma is a rare tumour. From Frazier-Grant's collection we were only able to utilize one, and from Vincent's collection we obtained five more. Since all of them had been fixed in 10 per cent formalin for a long time we could not undertake biological determinations of either serotonin or catecholamines. On the other hand, the content of serotonin and of norepinephrin is relatively low in the normal pineal body, but such a consideration

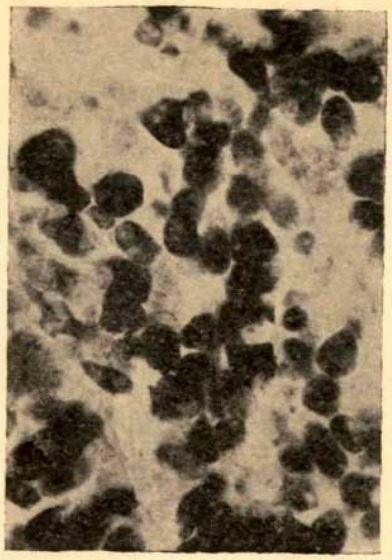

Fig. 1. Pinealoma. The parenchymatous cells of the tumour have numerous intracytoplasmic argentaffin granulations (Rio Hortega method)

does not clarify the histochemical significance of argentaffin cells in pinealomata, since in the normal organ the number of argentaffin cells is scarce, and its morphology is notably different from that of neoplastic argentaffin cells.

Similar differences and resemblances are found in other tumours formed by argentaffin cells. Special mention should be made of carotid body chemodectoma. In this tumour, parenchymal cells emit a long process ending in a juxtavascular club-shaped thickening[6], and they are quite similar to the normal pineal body parenchymal cells[7], as demonstrated by tissue culture[8]. Such unipolar cells are associated in chemodectoma with argentaffin cells, in such a way that in the latter they closely embrace the former[9]; in the narrow space between the embracing argentaffin cell and the unipolar chief cell, nerve endings running towards the Hering nerve are located. In the case of pinealoma, synaptic complexes similar to those in chemodectoma are demonstrated utilizing Rio Hortega's method. Moreover, both the carotid body and normal epiphyses receive abundant efferent nerve supply. Notice the similarity between the normal carotid body and chemodectoma on one hand, and between pineal body and pinealoma on the other hand. If we add to such similarities the observation by Hughes and Smith[10], who have described a chemodectoma in the pineal region, it seems justified to insist on the hypothesis of the aforementioned authors according to which the pineal body could be a chemo-receptor organ.

IMMUNOLOGY

Effect of 8-Azaguanine on the Specificity of Antigens synthesized by *E. coli* B/r_2

Roblin *et al.* synthesized azapurine analogues of naturally occurring purines and showed their ability to inhibit the growth of *E. coli* and *S. aureus*[1]. Since then many investigators have utilized analogues of purines and pyrimidines in studies of cell metabolism and protein biosynthesis[2–7]. The purpose for our initiating an investigation of the effects of purine analogues on growing cells was to explore the possibility of using such analogues to induce metabolic errors in the biosynthesis of protein antigens that would result in immunologically altered proteins. It was anticipated that this work would also contribute to our knowledge of protein biosynthesis because immunochemical methods are particularly well suited for differentiating even closely related substances on the basis of their immunological specificities.

E. coli B/r_2 and Ehrlich–Lettré mouse tumour ascitic cells were selected as examples of bacterial and mammalian cell types. The following is a preliminary report on the effects of 8-azaguanine on antigens synthesized by *E. coli* B/r_2.

Cells were cultured in 2-l. Erlenmeyer flasks with continuous shaking. Fifteen ml. of a 12-h. old culture were used to inoculate 500 ml. of a synthetic medium, and growth was continued for 48 h at 36° C.

E. coli cells were similarly grown in a medium containing 600 μg/ml. of 8-azaguanine, a concentration resulting in a 50 per cent decrease in the turbidity of the cell suspension after 10 h of growth. The cells were gathered by centrifuging the cultures, washed twice with citrate–saline buffer and resuspended in buffer containing sodium cholate in a final concentration of 1 per cent to minimize the degradation of RNA by nucleases. The suspension was sonicated for 2 h and then centrifuged to give an extract.

The extract of cells grown in the absence of 8-azaguanine was used to immunize rabbits. Each rabbit was injected intravenously three times weekly for four weeks, receiving a total of 18 mg nitrogen. Blood was collected from the rabbits one week following the last injection.

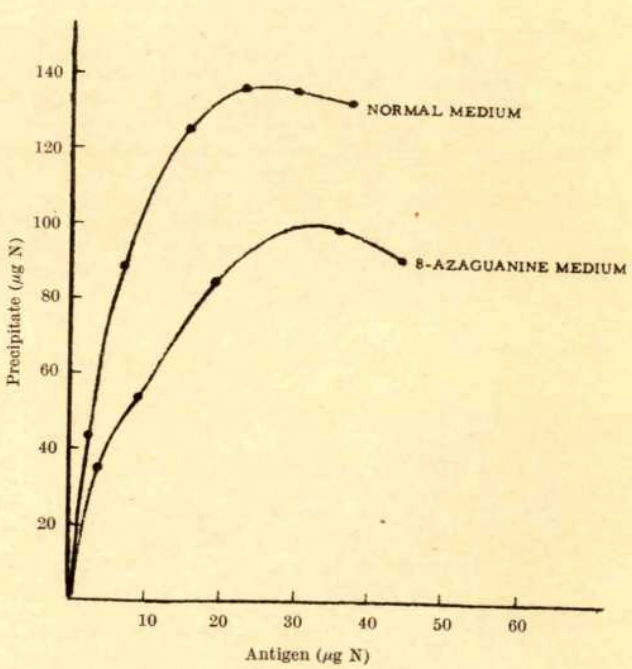

Fig. 1. Quantitative precipitin analysis of antigens in extracts of *E. coli* collected from a normal growth medium or one containing 600 μg/ml. of 8-azaguanine. The ordinate is the quantity of precipitate formed per reaction mixture, each containing 0·2 ml. rabbit antiserum produced by immunization with an extract of normal *E. coli* cells

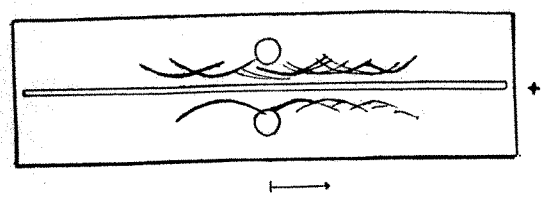

Fig. 2. Immunoelectrophoretic analysis of antigens in the same extracts of *E. coli* used for the quantitative precipitin analysis shown in Fig. 1. The extract of cells grown in a normal medium was placed in the upper circular well and the extract of cells grown in a medium containing 8-azaguanine was placed in the lower well. The rabbit anti-normal *E. coli* extract was added to the central trough parallel to the direction of migration toward the anode (+)

The resulting antisera were analysed for precipitating antibodies, reactive with antigens in extracts of cells grown in the absence or presence of 8-azaguanine, by the quantitative precipitin method of Heidelberger and Kendall[8] or by the gel-diffusion methods of Grabar and Williams[9] and Ouchterlony[10].

The results of the quantitative precipitin analysis are shown in Fig. 1. The maximum amount of precipitate formed during the reaction of antiserum with the extract of cells grown in a normal medium was significantly greater than that obtained in the reaction with the extract from cells grown in the presence of 8-azaguanine. This difference was due either to the deletion of certain antigens as the result of the presence of 8-azaguanine or to a marked alteration in their immunological specificity. A comparable analysis using antiserum against an extract of cells grown in the presence of 8-azaguanine is needed before one can decide between these two possibilities.

In order to determine the number of antigens affected by the presence of 8-azaguanine in the culture medium, the reactions between antiserum and extracts of the two types of cells were followed by immunoelectrophoresis. The results of this analysis (Fig. 2) showed quantitative differences in the concentrations of some of the antigens, particularly one in a slow-migrating fraction. The antiserum was absorbed with an excess of the 8-azaguanine cell extract and analysed by the double diffusion method of Ouchterlony. No antibody was detected in the absorbed antiserum against any antigen in the 8-azaguanine cell extract but it contained at least three antibodies against antigens in the normal cell extract. Thus, the 8-azaguanine was shown to affect markedly only a small number of the antigens synthesized by *E. coli* under the growth conditions used. Chantrenne[6] also reported a differential effect of 8-azaguanine in his examination of the enzymatic specificity of penicillinase and catalase synthesized by *B. cereus*. Because of the great sensitivity of the immunological specificity of an antigen to changes in its structure and because so many cell constituents, regardless of their other biological properties, are potentially immunogenic, the examination of the effects of antimetabolites on cellular constituents as antigens makes it feasible to study their possible effects on the biosynthesis of a greater number of substances.

RADIOBIOLOGY

Effect of Ultra-violet Light on Skin Collagen

It is now widely accepted that the uncovered sun-exposed skin of man 'ages' more rapidly than covered skin. The most marked effect of such ageing is atrophy of dermal collagen. The mechanism of this atrophy is not known, and we therefore examined the effect of irradiation with ultra-violet light on the collagen fractions of isolated mouse skin.

Thirteen male and nine female heterozygous pigmented hairless mice (obtained from the Institute of Animal Genetics, Edinburgh) were killed by breaking their necks. The skin was incised ventrally and dorsally along the mid-line and stripped off to the ears, snout, paws and tail. Fat was pared off, and the two approximately equal half-pelts from each mouse were blotted, weighed, and pinned out on to cork boards, epidermis uppermost. One half-pelt from each mouse was covered with black paper and the other was left exposed. The skins were put in a deep freeze (temperature $-20°$ C), the top of which was removed. After 30 min for temperature equilibration, ultra-violet light from a medium-pressure Hanovia mercury arc lamp (504/4 type arc tube) was directed vertically down from a distance of 32 cm on to the covered and exposed skins for a period of 15 h at a rate of $1{\cdot}66 \times 10^5$ ergs cm^{-2} sec^{-1}. After thawing the half-pelts were finely cut with a scissors, and the saline and citrate soluble collagen fractions were extracted by the method of Jackson[1]. The residue was heated with 5 per cent trichloroacetic acid and the collagen was measured as hydroxyproline in the residue and in the saline and citrate fractions by the method of Neuman and Logan[2]. A 100 μg/ml. solution of hydroxyproline in 0·46 *N* hydrochloric acid was exposed to the same degree of ultra-violet irradiation for 14 h at laboratory temperature in a soda glass tube. There was no change in the concentration of hydroxyproline.

After thawing, it was noticed that the skins which had been exposed to ultra-violet light looked and felt leathery, and were difficult to cut, while the unexposed control skins appeared to be unchanged.

Table 1. Skin Collagen Fractions in μg Hydroxyproline/g of Original Half-pelt

Mouse	Sex	Control half-pelt			Ultra-violet exposed half-pelt		
		Saline	Citrate	Residue	Saline	Citrate	Residue
1	M	53	120	13,300	37	<10	14,500

7	M	—	49·5	4,350	—	<10	6,350
8	M	—	62	6,675	—	<10	—
9	M	—	50	3,550	—	<10	4,060
10	M	—	187	5,920	—	<10	5,730
11	M	25·7	148	11,300	17·2	27·2	10,766
12	M	19·8	106	9,250	13·1	15·0	9,425
13	M	31·2	84	8,400	14·4	18·7	8,880
1	F	26	53	5,050	<10	<10	5,230
2	F	40	115	4,800	<10	<10	7,650
3	F	29	50	7,150	<10	<10	6,720
4	F	38	103	7,270	<10	<10	5,570
5	F	—	67	6,150	—	<10	10,650
6	F	—	44	8,810	—	<10	8,700
7	F	17·9	37	3,240	<10	<10	3,580
8	F	24·6	49	4,070	15·9	<10	5,650
9	F	25·4	56	3,290	13·1	13·1	4,650

The chemical findings (Table 1) are that the saline and citrate collagen fractions were decreased considerably after exposure to ultra-violet light. Presumably, therefore, ultra-violet light precipitates an insoluble collagen from the saline and citrate soluble collagens. It remains to be seen whether this is due to an increased number of cross-linkages within the collagen fibrils or to denaturation of the collagen. Although the decrease in the soluble collagen fractions was considerable, in absolute terms, the amounts concerned were too small to give a detectable increase in the insoluble collagen residue (Table 1). Although there

was no clear-cut sex difference, the collagen fractions tended to be less in the females than in the males both before and after exposure to ultra-violet light. This is in keeping with our observations on human skin (Shuster and Bottoms, in preparation). Whether or not the 'ageing' of human skin exposed to the Sun is related to the effect which we have observed, it is clear that ultra-violet light has a profound effect on the physico-chemical state of the dermal collagen.

We thank the Medical Research Council for a grant to one of us (S. S.).

Influence of Temperature and Medium on the X-ray Sensitivities of Leukæmia Cells *in vitro*

Hollaender and Stapleton[1] demonstrated with various strains of *E. coli* that the fraction of cells which survived (that is, retained ability to form colonies) from a given dose of X-rays could be significantly increased if the cells were maintained for some hours before being plated out at either a sub-optimal temperature or in medium enriched with yeast extract (see also Alper and Gillies[2], for restorative action of different media). We have now observed what would appear to be comparable phenomena with murine leukæmia cells *in vitro*. An effect of serum on the radio-sensitivity of mammalian cells has also been found by de Oca *et al.*[3].

Fischer[4] developed a medium in which *L*5178 *Y* cells originating from a radiation-induced leukæmia in a *DBA*/2 mouse can be cloned and grown *in vitro* in suspension culture. These cells are still strain-specific to *DBA*/2 mice in which a tumour can be produced from one cell. Alexander and Mikulski[5] found that in the original Fischer medium these cells showed a semi-logarithmic dose-survival curve with a small initial shoulder typical[6] for mammalian cells in culture. Two mutants, both diploid, and differing by a factor of 2·1 in radiosensitivity, were studied[5]. These are referred to as the sensitive and resistant strains. Following Fischer, it was found that peptone could be eliminated from the medium. This produced a small change in the survival curve and mainly affected the extrapolation number (Fig. 1). Extensive dialysis and ultracentrifugation of the horse serum did not alter the radiosensitivities further, but replacement of the horse serum by the following bovine plasma fractions: V; 0·36 per cent (serum albumins); II; 0·36 per cent (γ-globulins); IV–4; 0·005 per cent (α_2-globulins, etc.) obtained from Armour Laboratories did produce pronounced changes in the X-ray sensitivities (Fig. 1). In this 'simplified' medium the mean doubling time of a sensitive cell suspension was unaltered (11–12 h) but that of the resistant strain was lengthened from 13–14 to 18–20 h at 37° C. Cells grown and maintained after irradiation in the simplified medium were more sensitive to X-rays (220 kVp.); the survival curve becomes steeper in both cases whereas the extrapolation number is little affected (see Fig. 1). The sensitive and resistant strains respond equally to the replacement of horse serum by the bovine plasma fractions when this effect is expressed as the change in the slope of the exponential portion of the survival curve, that is, the dose reduction factor due to the change in medium is 1·7 and 1·8 for the sensitive and resistant strains respectively. For technical reasons it is difficult at present to establish whether the full

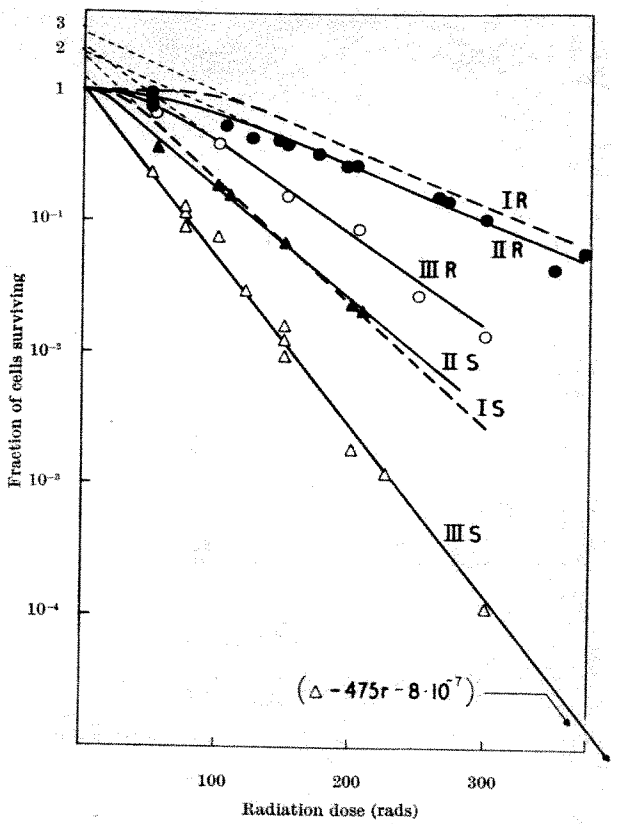

Fig. 1. Influence of culture medium on radiosensitivity. Lymphoma cells grown on Fischer medium with the following additives: I, peptone and horse serum (data from ref. 5); II, dialysed and ultracentrifuged horse serum; III, bovine plasma fractions (see text). Curves labelled *S* and *R* represent the sensitive and resistant mutants respectively

sensitizing effect is obtained by a post-irradiation change of medium, but preliminary experiments indicate that the medium primarily influences post-irradiation processes.

In the simplified medium the survival of the sensitive cells could be varied by changing the temperature at which the cells were maintained in the first hours after irradiation with X-rays. An influence of temperature was first observed when cells were maintained both before and after irradiation at 34° C (mean doubling time 18 h). The cells in these conditions were 1·5 times more resistant (that is, D_0 at 34° C is 51 rads as opposed to 35 rads at 37° C) than those grown normally at 37° C. It became apparent that the major effect of temperature was a post-irradiation phenomenon since cells grown at 37° C showed a higher survival even when placed at the lower temperature only after exposure to X-rays.

Fig. 2 shows that the maximum recovery is attained by keeping cells for 9 h post-irradiation at the lower temperature before returning them to the standard temperature of 37° C. The reverse phenomenon (that is, 'sensitization') can be brought about by placing cells grown at 34° C for various times after irradiation at 37° C before returning them to 34° C (Fig. 2). Again, a period of some 9 h seems to be necessary for the full effect of temperature on survival to manifest itself. Moreover, the cells grown at 34° C, but kept for 9 h at 37° C after irradiation, seem to be somewhat more sensitive than those maintained at 37° C throughout. In other words, this treatment seems to exert a small sensitizing effect while lowering the temperature for some hours after irradiation increases survival. For the resistant cells the influence of post-irradiation temperature in the range studied is very much less than with the sensitive cells and the slopes of the survival curves at the two temperatures are the same within experimental error.

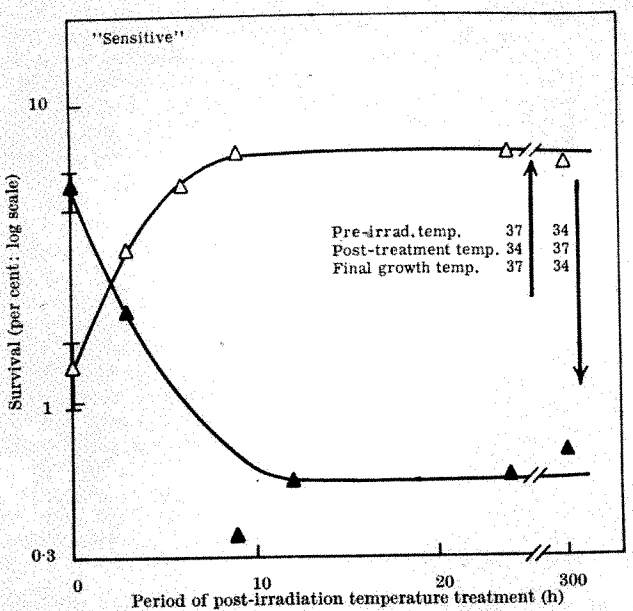

Fig. 2. Influence of post-irradiation temperature on survival of the sensitive lymphoma cell strain after a dose of 150 rads of X-rays. (Cells grown in 'simplified' medium.) △, Cells grown at 37° C and kept after irradiation for various times at 34° C; ▲, cells grown at 34° C and kept after irradiation for various times at 37° C

Indeed, if the two strains of cells are compared in the simplified medium at 34° C, then the difference in their radiation sensitivities is 1·3 (D_0 = 65 and 51 resp.) as opposed to 1·8 (D_0 = 62 and 35 resp.) at 37° C.

Ten years ago Hollaender and Stapleton[1] had found a parallel situation with *E. coli B*, where lowering the post-irradiation temperature aided the recovery of the sensitive strains much more than that of the resistant strain, so that under optimum recovery conditions the strains showed almost identical radiation sensitivities. Their conclusion that the difference in radiation sensitivities of the *E. coli B* mutants is related to post-irradiation recovery potential would appear to apply also to the different lymphoma cell strains in the simplified medium.

That post-irradiation conditions determine the magnitude of the radiation lesion has been known for forty years (cf. ref. 7). The first accurate measurements of such processes in mammalian cells was provided by Elkind and Sutton[8], who found that the sub-lethal damage sustained by cells and manifested as the shoulder in the survival curve was restored under normal culture conditions in some twelve hours after irradiation. We also found this phenomenon with the resistant strain of lymphoma cells in the full medium where the survival curve has a pronounced shoulder. Thus two exposures of 250 r. separated by 6 h gave a survival of 9 per cent as opposed to 1·2 per cent by a single dose of 500 r.

The experiments described here indicate the existence of two post-irradiation recovery mechanisms which are distinct from the Elkind and Sutton effect, since not the extrapolation number but the slope of the survival curve is altered, by medium composition and temperature.

Our experiments suggest that the mechanism of increasing survival of irradiated cells grown on the simplified medium by placing them in the full medium is different from that obtained by lowering the post-irradiation temperature since both mutants respond to medium changes while only the sensitive mutant is affected by temperature in the range studied.

The term 'recovery' has been used rather widely in this connexion since changes in survival can be brought about in many ways and the possibility that the metabolic processes responsible for developing the primary radiation injury are altered cannot be excluded.

Freeze-drying and Radiation Protection

Gamma-irradiation of *Bacillus subtilis* (N.C.T.C. 8236) spores revealed a marked protection if spores are first freeze-dried from certain carbohydrates. Freeze-drying from water did not produce a statistically significant effect. Protection was demonstrated after freeze-drying

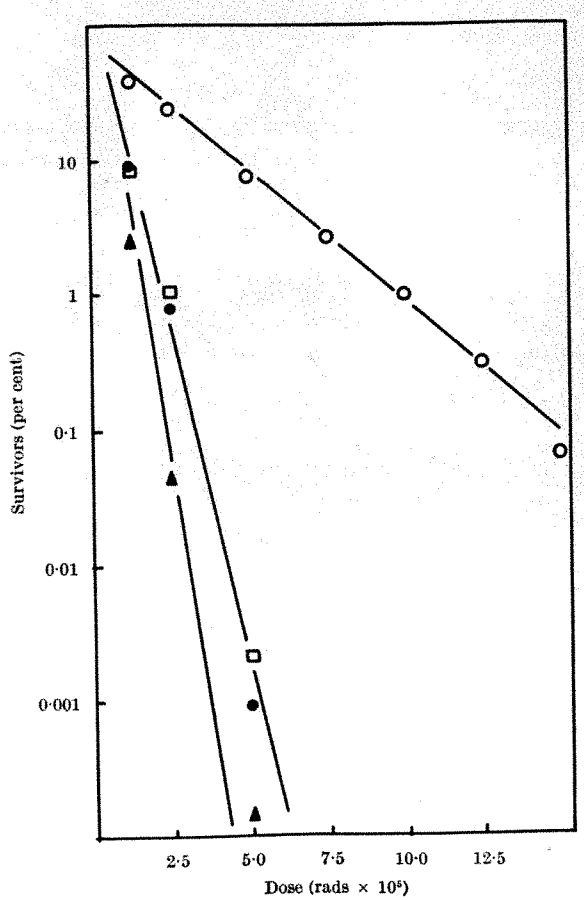

Fig. 1. Gamma-irradiation of *Bacillus subtilis* spores. Regressions of log per cent survivors against radiation dose for: □, aqueous suspension of spores; ●, suspension of spores in 5 per cent aqueous glucose; ▲, spores freeze-dried from aqueous suspension; ○, spores freeze-dried from 5 per cent aqueous solution of glucose

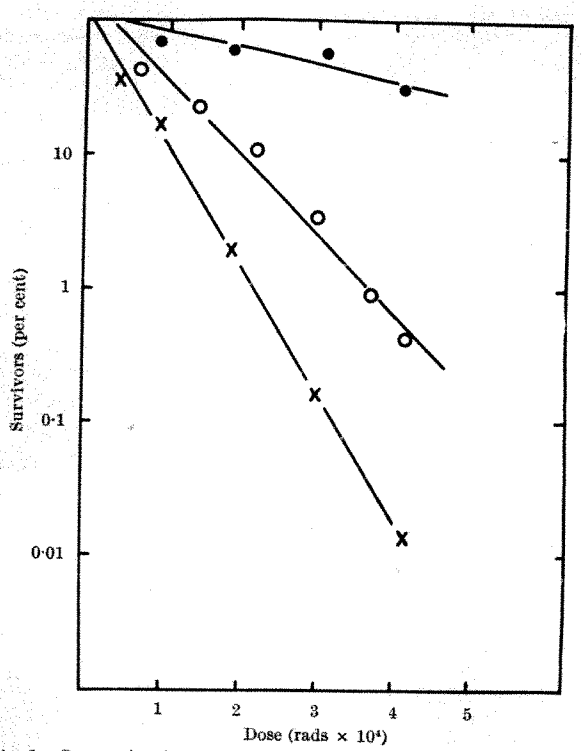

Fig. 2. Gamma irradiation of *Escherichia coli*. Regressions of log per cent survivors against radiation dose for: ○, aqueous suspension; ×, suspension in 5 per cent aqueous solution of glucose; ●, cells freeze-dried from 5 per cent aqueous solution of glucose

0·1 ml. samples at 0·01 mm mercury over phosphorus pentoxide for 16 h from 5 per cent aqueous solutions of glucose, lactose, or fructose, but not from maltose.

Viable counts were performed by a surface spread method (on 'Oxoid' peptone agar) and a tube dilution method ('Oxoid' peptone water). The former gave a higher recovery in every case, although conversion to per cent survivors resulted in there being no significant difference in the slopes of the regressions (log per cent survivors against dose) for the two counting methods under identical conditions.

The protection is apparently associated with the production of a 'glass' during the freeze-drying process. Maltose did not form a glass.

Subsequent work revealed a similar protective effect on *Escherichia coli CN* 1539 after freeze-drying from glucose.

BIOLOGY

Behavioural Differences between the Larval Stages of *Cirriformia tentaculata* (Montagu) from Drake's Island (Plymouth Sound) and from Southampton Water

A three-year investigation into the ecology of the cirratulid worm, *Cirriformia tentaculata* (Montagu), occurring on an inter-tidal mud-flat in Southampton Water, failed to reveal any trace of pelagic larval stages. These free-swimming stages have been shown by Wilson[1] to exist in a population of worms from Drake's Island.

The development of 'Southampton animals' from fertilized eggs was closely followed in the laboratory. The eggs and young worms were found to be morphologically identical with those from the Drake's Island population (illustrated by Wilson). However, the behaviour of the lecithotrophic trochophores and other larval stages was somewhat different. About 24 h after fertilization, eggs from the Plymouth population became strongly swimming trochophores. They remained pelagic as the trunk elongated, and did not settle on the bottom until they had lost most of their cilia, approximately 7 days later. On the other hand, trochophores which developed from eggs of the Southampton population remained on the bottom of their containers. At this stage, agitation of the water in the rearing vessels could sweep the trochophores into suspension. However, the larvæ were unable to maintain themselves by swimming and would sink to the bottom again within a few seconds. The post-trochophore stages possessed well-developed neurotrochs on which they glided slowly over the bottom of the culture dishes. Only strong agitation of the water could sweep these young worms into suspension.

It may be argued that the young animals did not leave the bottom of the containers because they were less vigorous than those in Wilson's cultures. However, the 'Southampton larvæ' (which were the product of naturally spawned males and females), if anything, grew at a slightly faster rate than the Plymouth forms. The larvæ remained on the bottom of their containers regardless of light conditions, temperature, or the oxygen content of the water.

It is known that certain species (for example, *Spio martinensis*, *Pygospio elegans*) produce pelagic and non-pelagic forms according to the time of the year[2,3]. Such a situation does not exist in the Southampton population of *Cirriformia* where non-pelagic larvæ are produced throughout the breeding season. No observations for a continuous yearly period are available for Plymouth *Cirriformia*.

Clearly, the larval stages of the Southampton population are demersal, the behavioural dissimilarity between the two populations being due perhaps to the existence of two distinct 'physiological races' within the species. Indeed, adult *C. tentaculata* from Plymouth which I have seen are much larger than the biggest adults from Southampton.

I thank Dr. D. P. Wilson and Prof. J. E. G. Raymont for their interest.

Nemasperm and Pituitary Inhibition

It has been shown that bovine semen—as well as that of man, dog, rat and cock—displays, among its manifold non-gametic biological activities[1], a constant and fairly strong pituitary-inhibiting action[1–3]. This effect does not seem to be proportional to the very low androgenic activity of the semen. Its relation to the well-established œstrogenic activities appears also always to be questionable[2].

It seemed to be of some interest to gain more information on this peculiar activity.

The inhibiting activity of the total semen, or centrifuged, washed and resuspended nemasperm in saline was tested on 120 parabiont pairs (female spayed Wistar albino rat 120–140 g + female immature 60–80 g), forming 9 groups, each of 7–15 pairs, as well as on the gonadotrophin-level in the urine of female spayed Wistar albino rats of 150–180 g: extractions and determinations were according to Loraine and Brown[4,5]. Investigations were also carried out on the spayed female

adult Wistar albino rats, using the ascorbic acid depletion method, according to Roe and Kuether[6,7]; and also on the weight of the testis in the immature cockerels, totalling 100 animals, in 2 groups. Finally, we recorded the usual histological modifications in the pituitary of the spayed adult female rat. As a result of this first investigation, it was possible to see that 0·3–0·6 ml. of bull total semen (or reconstituted; also as centrifuged, grounded and homogenized nemasperm) when given intramuscularly, or intraperitoneally, in a single injection, can induce, for example, the following modifications: group of 8 pairs of animals killed after 5–7 days: mean ovarian weight (controls), $48{\cdot}57 \pm 3{\cdot}38$ mg (*S.E.*); mean ovarian weight (treated), $22{\cdot}46 \pm 4{\cdot}23$ mg, $t = 4{\cdot}90$ ($P \leqslant 0{\cdot}01$).

For the gonadotrophin-level, work was carried out on 110 animals: the results, expressed as μg of acetone powder of rat pituitary (see quotations[6]), were as follows: Basal: 26·40 ± 3·8 μg; treated: 12·0 ± 2·2 μg. With the ascorbic acid depletion, we investigated 15 animals.

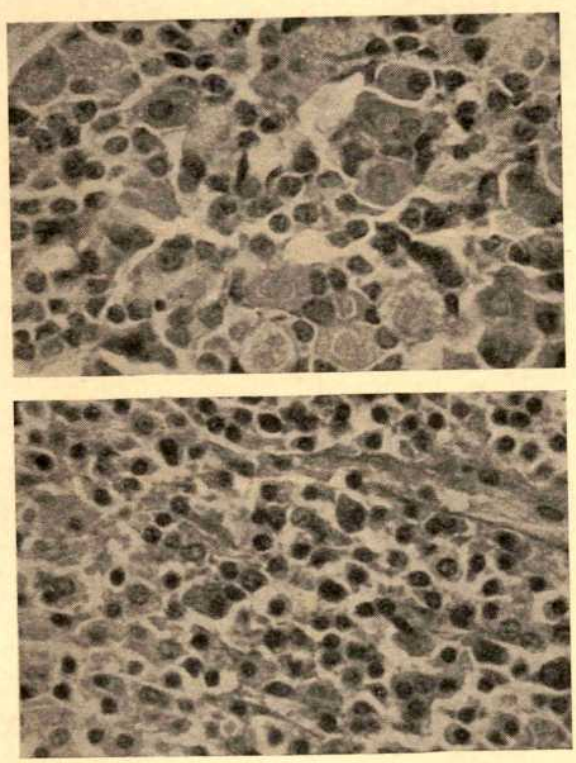

Fig. 1. *A*, control; *B*, treated animals. Spayed rats, 120 g, injected at the 1st, 2nd, 3rd and 4th day with 0·5 ml. of the deproteinized, lipid and œstrogen conjugated-free extract from nemasperm homogenate. Animals killed after 21 days. Hypophysis fixed with Mueller phenolic; col. with periodic acid, Pearse technique (Dr. Spazzoli)

Control: $47{\cdot}5 \pm 5{\cdot}1$/100 mg ovarian weight. Treated: $37{\cdot}20 \pm 4{\cdot}6$/100 mg ovarian weight. Finally, we used 100 Kimber cocks, 45 days old: each animal was given a single dose of 1·5 ml. bovine total semen, intramuscularly. From 50 animals, killed after 50 days, a relative weight of testis (controls) of $0{\cdot}406 \pm 0{\cdot}243$ g was recorded. From 50 animals killed after 50 days, the relative weight of testis (treated) was $0{\cdot}280 \pm 0{\cdot}063$ g (difference 0·406–0·280: significant at $P = 0{\cdot}05$) (data already published in ref. 3). In the animals killed after 50 days, the relative weight of the crest (controls) was 10·252 g; that of the treated 9·144 g. When killed after 90 days (50 animals) the weights of the testis and crest are less than the controls; although statistically not significant.

In the pituitary of the spayed albino rat (21 days after castration) it is easy to see inhibition (Fig. 1).

The activity of some fractions was also tested on 66 parabiont spayed females + immature females, recording the ovarian weights. Table 1 gives the results of these experiments.

From the foregoing data it may be tentatively concluded that nemasperm seems apt to elaborate something capable of inhibiting the gonadotrophic secretions, namely, F.S.H. This action does not seem referable to the androgenic content. The biological activity seems to be referable to a possible non-lipidic, non-proteic, hydrosoluble, dialysable ($\varphi < 10$ mμ), thermolabile ($t > 100°$ C) molecule or groups of molecules. The action of the possible œstrogenic residual content may still be open to question.

Linear Relationship between Temperature and Uptake of Oxygen in *Euglena gracilis*

Changes in incubation temperature result in changes in the growth rate, the dry weight and the length of the lag phase of the growth cycle of streptomycin-bleached *Euglena gracilis*[1]. It appears that, within limits, low temperatures favour protoplasmic growth whereas high temperatures favour cell division. It was considered of interest to extend these observations to an investigation of the effects of various incubation temperatures on the rate of respiration of *Euglena*.

Experimental and stock cultures of a streptomycin-bleached strain, *SM-L*1, of *Euglena gracilis* var. *bacillaris* were grown axenically in the dark on 250 ml. of the defined Cramer–Myers medium[2], as modified[3], in 1 litre culture flasks. Sodium acetate (0·061 M) was the sole carbon source for growth. Cultures were inoculated from stocks growing exponentially at 25° and began growth at different temperatures (see Table 1) at a cell density of $14–20 \times 10^3$ cells/ml. Oxygen uptake of *Euglena* was determined manometrically by the direct method of

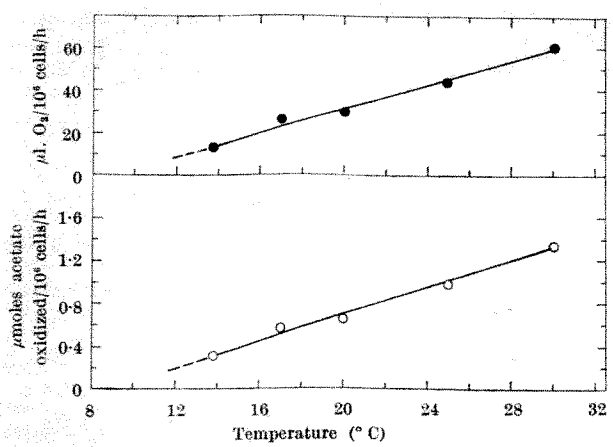

Fig. 1. Uptake of oxygen by *Euglena* at different temperatures (upper graph) and the amount of acetate oxidized by *Euglena* at different temperatures (lower graph)

Warburg[4] at the same temperatures at which the cells were grown. *Euglena* were concentrated by centrifugation at 2,000 r.p.m. for 2 min only, since prolonged or repeated centrifugation inhibits the oxygen uptake of these protozoa[5]. The cells were resuspended to a density of $5{\cdot}1–8{\cdot}5 \times 10^5$ cells/ml. in fresh medium and 2-ml. quantities were pipetted into Warburg vessels. Readings were taken at 5-min intervals for 45–60 min. Quadruplicate dry weight samples were taken at the same time as samples were taken for respiration. Dry weights of *Euglena* at various temperatures have been presented previously[1]. However, in the light of the further finding that the dry weight of these *Euglena* remains constant only during the mid-portion of the logarithmic growth phase (at least at 25°) (ref. 6), the measurements recorded here were taken at each temperature on cells grown to the mid-log phase. Temperatures below 13·8° and above 30° were not investigated because of the extremely slow growth rate of *Euglena* at low temperatures and the inhibition of the growth of the present *Euglena* at 32° (ref. 1).

Dry weight is constant from 17° to 25° but is increased at 13·8° and decreased at 30° (Table 1). The Q_{O_2} (μl. O_2/mg weight/h) of *Euglena* increases as temperature increases and is 7·5 times higher at 30° than it is at 13·8°. When the Q_{O_2} of *Euglena* is plotted against temperature a linear increase in oxygen consumption results between 13·8° and 25° followed by a sharp increase between 25° and 30°. However, when the oxygen uptake of *Euglena* is plotted as μl. $O_2/10^6$ cells/h versus temperature, a linear relationship is observed (Fig. 1) throughout the range of 13·8°–30°. For each degree increase in temperature, the oxygen uptake per 10^6 cells increases 2·85 μl. O_2/h. Therefore, a consideration of the data on a dry weight basis alone would obscure the result that the average cell linearly increases its oxygen consumption over the entire temperature range investigated (Fig. 1). To illustrate further these latter data, the μmoles of acetate oxidized per 10^6 cells per h versus temperature were calculated from the data given in the upper portion of Fig. 1 and are shown in the lower portion of Fig. 1. For each degree increase in temperature, the acetate oxidized per 10^6 cells increases $6{\cdot}37 \times 10^{-2}$ μmoles/h.

It is clear that temperature differentially affects the growth rate, dry weight and the oxygen consumption of the present *Euglena*. The growth rate increases linearly up to 25° and then levels out between 25° and 30° (ref. 1), whereas the dry weight decreases with rising temperature (Table 1). In contrast, the respiration rate increases linearly throughout the temperature range, 13·8°–30° (Fig. 1). Thus, it appears that the dry weight loss at high temperature does not involve the respiratory machinery of these *Euglena*. As a result, temperature becomes a tool for separating, at least partially, variable metabolic processes related to growth in *Euglena*, especially at the high temperatures favouring cell division.

Table 1. Effects of Temperature on the Dry Weight and Q_{O_2} of *Euglena*

Temperature (° C)	Dry weight (mg/10^6 cells)	Q_{O_2} (μl. O_2/mg dry weight/h)
13·8	1·63 ± 0·04*	8·5 + 0·1*
17·0	1·24 ± 0·13	20·6 ± 1·1
20·0	1·22 ± 0·05	23·6 ± 1·4
25·0	1·24 ± 0·03	33·5 ± 1·1
30·0	0·94 ± 0·05	63·7 ± 3·3

Seed Dispersal in *Salicornia pusilla*

The method of seed dispersal in the annual glasswort *Salicornia pusilla* (Chenopodiaceae), a local plant of coastal salt-marshes, is of interest. In this species the seeds are deeply immersed in the fleshy tissues of the stem cortex, and are covered (except at the minute orifice) by the long-persistent perianth. In all other European species of this genus, the inflorescence consists of decussately paired 3-flowered cymules. In *S. pusilla*, however, these cymules are single-flowered. A normal fruiting head (Fig. 1) contains 4–10 seeds and is shed from the parent plant, as the seeds ripen, by the development of an abscission layer. The seeds are retained within the cortical tissues even when the fruiting head has become separated.

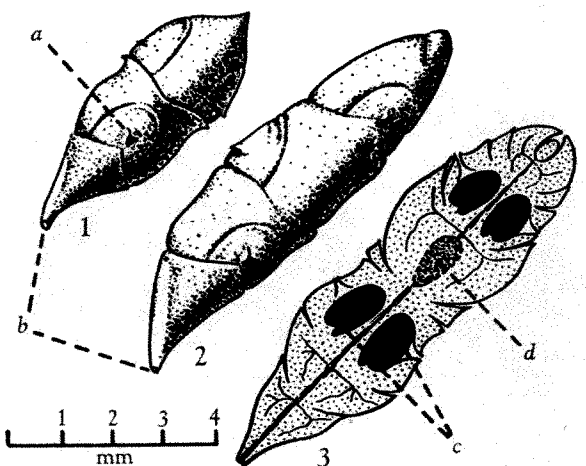

Fig. 1. 1 and 2, Detached heads with, respectively, four and six perianths; 3, longitudinal section through a head, showing immersed seeds. *a*, Orifice to perianth; *b*, points of abscission from parental plant; *c*, pair of seeds in plane of section; *d*, position of pair of seeds in plane at right angles to section

I have shown experimentally that these fallen heads will float in sea-water for up to three months, and that towards the end of this time the seeds may germinate *in situ*. In October and November detached heads may be seen stranded at or near high-water mark, where they have been carried by tidal action. This is presumably the reason for the occurrence of this species in its characteristic habitat just below the often conspicuous zone of *Halimione portulacoides*. *S. pusilla* is found in almost all suitable habitats in south and south-west England, and also in certain more isolated localities on the southern coasts of Wales and Ireland. It occurs also on a few salt-marshes in Brittany.

These outlying localities suggest the possibility of long-range dispersal by means of the floating heads, aided by the longevity of the seeds in sea-water.

Fruits of other salt-marsh plants (for example, *Halimione portulacoides* and *Suaeda maritima*) will also float in sea-water, being buoyed up by the air contained in their tissues, and the naturally isolated seeds of other *Salicornia* spp. will float (if dry) through air being held between the short curved hairs on the testa. I believe, however, that *S. pusilla* is the only example known in the British flora where whole intact fruiting heads may be dispersed by floating in sea-water.

MICROBIOLOGY

A Photographic Method for the Detection of Rare Bacterial Mutants in the Replica Plating Technique

The replica plating technique, devised by J. and E. M. Lederberg[1], has found wide application to the isolation of bacterial mutants that cannot be automatically selected, for example, of mutants which lack the ability to synthesize a given growth factor or to ferment a given sugar, and of revertants from drug resistance to sensitivity. A great number of colonies should be replicated, if the mutation frequency is low. When several hundreds of colonies per plate are used, however, it becomes difficult, if not impossible, to compare the replicas visually. This communication describes a photographic method which permits the evaluation of plates containing many more colonies than would be feasible by visual comparison.

The method emanated from studies on the resistance of *Escherichia coli C* to bacteriophage φX–174 and its host range mutants[2]. If a wild-type lysate of φX-174 is plated on phage-resistant mutants of *E. coli C* (designated by C/φ), normally a very small number of host-range mutant plaques are observed (one per 10^9 viable particles or less). After a fortuitous finding in similar work with *Shigella*[3] we suspected that a small class of C/φ-mutants (to be referred to as $C/\varphi S$) could be procured, which would permit growth of a much higher number of host-range mutants if wild-type phage was plated (about one per 10^7 particles). Colonies of these mutants could possibly be found among the abundance of C/φ-colonies if they were replicated on to a plate without phage and on to a plate containing a large amount of wild-type phage. A colony of $C/\varphi S$ will not develop on the latter plate when its cells are infected by a host range mutant present in the wild-type lysate. Since in the first experiments no $C/\varphi S$-colonies were found, it became desirable to examine many more colonies per plate.

The method used for handling these dense platings was applied as follows. Of the phage-resistant colonies on the master plate grown after seeding with wild-type bacteria and wild-type phage, two replicas were made, as described here. Of both replicas contact prints (negatives) were made by placing the plates on light-sensitive paper (Dalcopy paper, kindly supplied by Dalco, Soestduinen, The Netherlands) and exposing them to light the rays of which had been made nearly parallel. Pictures were obtained as shown in Figs. 1*a* and *b*. From the print representing the second replica a positive was made on the Dalcopy reproduction apparatus (Fig. 1*c*). The print of the first replica was then placed upside down on this positive in such a way that the white colonies seen on Fig. 1*a* conform to the black ones of Fig. 1*c*. This combination was reproduced in the Dalcopier on another sheet of paper. As, in general, the colonies on the replicas

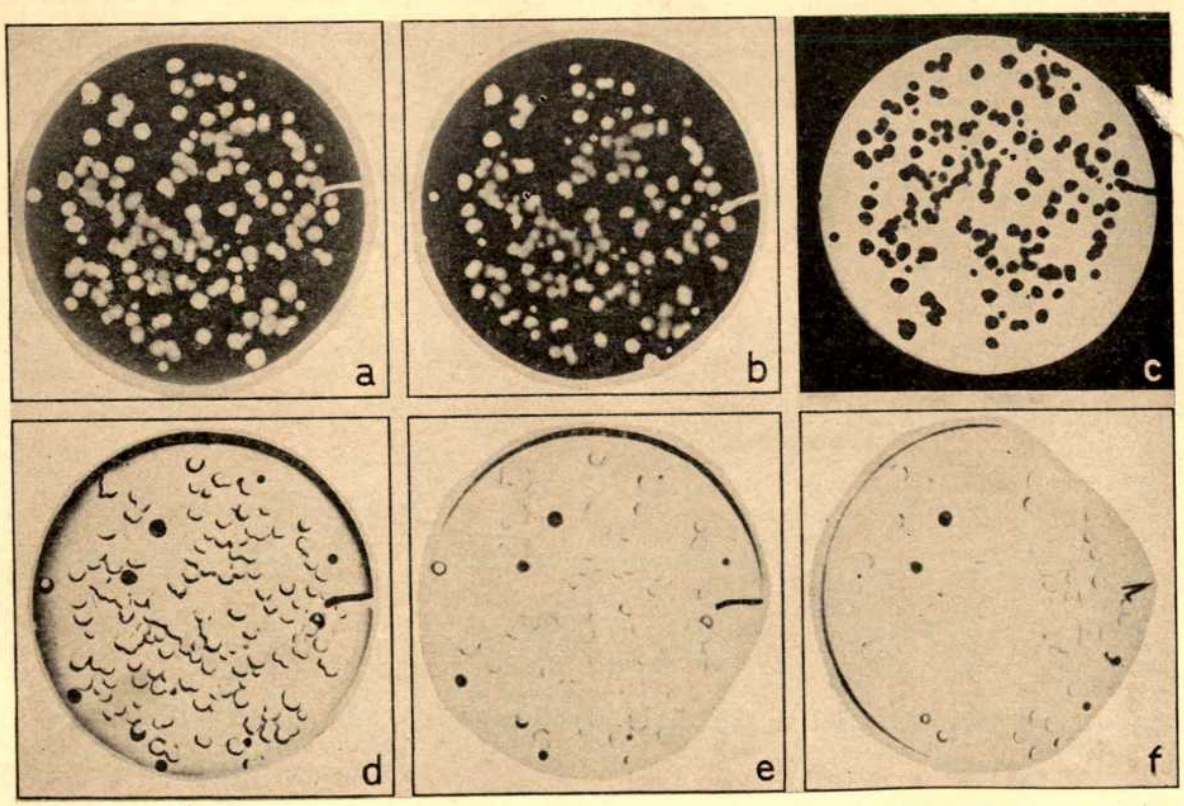

Fig. 1. Prints obtained using the photographic detection method. The master plate was prepared by spreading *E. coli C* and φX-174; after incubation it was replicated fourfold on plates containing: no phage (1), φh-phage (10^5 particles per plate) (2), *idem*. (3), and no phage (4), respectively. *a*, Print of plate (1-); *b*, print of plate (2); *c*, positive of *b*; *d*, relief-print of *a* upside down on *c*, a little shifted and under-exposed; *e*, *idem*, but not shifted and heavily under-exposed; *f*, *idem*. for plates (4) and (3). The two dots occurring at the same site on *e* and *f* represent colonies that proved to be $C/\varphi S$-mutants. They need not necessarily be of independent origin

differ slightly in shape, so that fitting on prints 1*a* and 1*c* is not perfect, the result is a kind of relief-print. This impression is strengthened when the two prints are a little shifted with respect to each other, as is shown in Fig. 1*d*. The print is under-exposed in order to obtain a white background. The relief pattern is helpful in locating the black dots on the first replica, which appear as a consequence of the lacking of some colonies on the replica containing phage. These dots show most clearly on a print like Fig. 1*e*, which is made without shifting and which is heavily under-exposed. The dots may represent the mutant colonies looked for; however, they can also be due either to irregularities in the agar layer of the first plate, for example, air bubbles, or to colonies that have not been replicated on to the second replica. This incompleteness of the replication was especially observed along the edge of the replica.

We therefore consider the following refinement of the method to be of great value. Four instead of two replicas are made on to plates containing no phage (1), phage (2), phage (3), and no phage (4), respectively. By comparison of the relief-print of the plates (1) and (2) with that of (4) and (3), mutant colonies, which should appear on both prints, are easily detected (compare Figs. 1*e* and 1*f*). This photographic method enables testing up to 1,000 colonies per plate.

Master plates were prepared by spreading about 5×10^8 cells of *E. coli C* and 10^4 to 10^6 φX-174 particles on the agar surface of a Petri dish. The number of phage particles should be at least 10^4 per plate in order to obtain confluent lysis of the bacterial layer after incubation (18 h at 32° C). High concentrations of phage should be avoided, however, since otherwise there is a greater probability that colonies of the mutants looked for will be lysed by host range mutants, either brought on the plate or originated in an early stage of phage growth. About 600 colonies could be seen; the diameter was about 2 mm.

These colonies were replicated by means of short-poled velveteen on to four plates (see above) containing broth agar, described by Zahler[4]. Two plates had been seeded with about 5×10^{10} wild-type phage particles, about 20 min before use. In order to obtain small colonies we incubated the replicas for 18 h at 28° C. Phage growth is not greatly depressed at this lower temperature, since neither efficiency of plating nor plaque size varies appreciably on incubation between 26° and 37° C.

For demonstrative purposes we present in Fig. 1 a series of prints of an experiment, in which a host-range mutant (φh) of the phage was used instead of the wild-type. This affords a much better selection for the mutants, as it might be expected that all $C/\varphi S$-colonies would be lysed by the host range particles. The latter do not inhibit the growth of the common C/φ-mutants (detailed information will be published elsewhere[2]). In this way a smaller number of C/φ-colonies needed to be replicated in order to obtain positive results.

This photographic method may be regarded as a useful and economical amplification of the replica plating technique, especially if low mutation frequencies are to be expected. It was successfully applied to the isolation of rare phage-resistant mutants of *E. coli C* that permit growth of a relatively high number of host range mutants if wild-type bacteriophage φX-174 is plated on these strains.

VIROLOGY

Electron Microscopy of Myxoma Virus

Ruska and Kausche[1] and Farrant and Fenner[2] demonstrated a close similarity, both in size and superficial morphology, between myxoma and vaccinia viruses. This, together with the demonstration of similarity in the pathogenesis of myxomatosis and other pox virus diseases, was considered by the latter authors to justify the inclusion of myxoma virus within the pox group. Further justification for this view has now been obtained by a comparison of the morphology and fine structure of myxoma and vaccinia viruses using the negative contrast technique of Brenner and Horne[3].

Monolayers of a rabbit kidney cell line (*Gl. RK* 13, kindly supplied by Dr. Christofinis of Messrs. Glaxo, Ltd.) were infected with an input multiplicity of three infective units per cell of the Cornwall strain of myxoma virus. After incubation for 48 h at 35° C the infected cells were

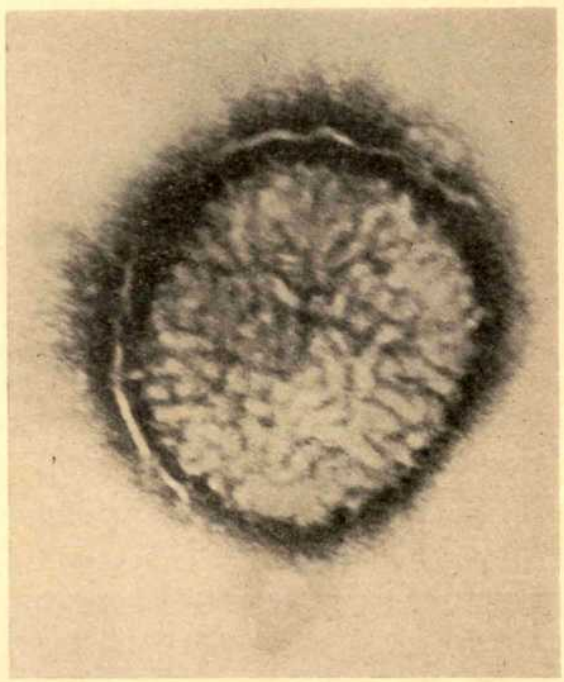

Fig. 1. Myxoma; no PTA penetration (× 160,000)

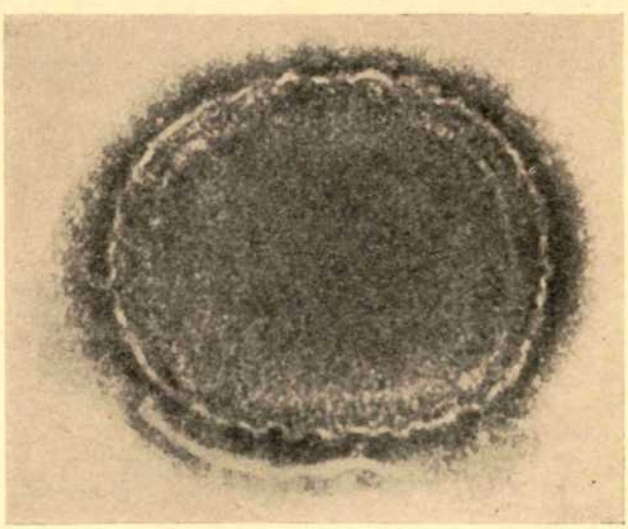

Fig. 2. Myxoma; PTA penetration (× 160,000)

washed free of medium, scraped off the glass and ultrasonically disrupted in a small volume of tissue culture medium. Cell debris was removed by centrifugation at 3,000*g* for 10 min and the virus then deposited at 40,000*g* for 30 min. The pellet containing the virus was dispersed by ultrasonic treatment in a small volume of distilled water and mixed with an equal volume of 2 per cent sodium phosphotungstate, *p*H 6·0. After standing at room temperature for 10 min, drops of the mixture were placed on carbon-coated 'Formvar' grids and examined in the Siemen's 'Elmiskop 1' electron microscope using double condenser illumination at 80 kV accelerating voltage and magnification, 80,000 times.

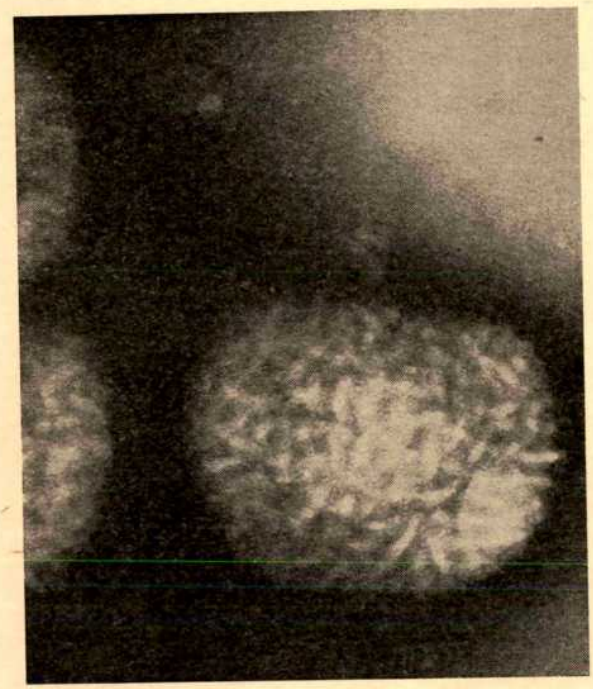

Fig. 3. Vaccinia; no PTA penetration (× 160,000)

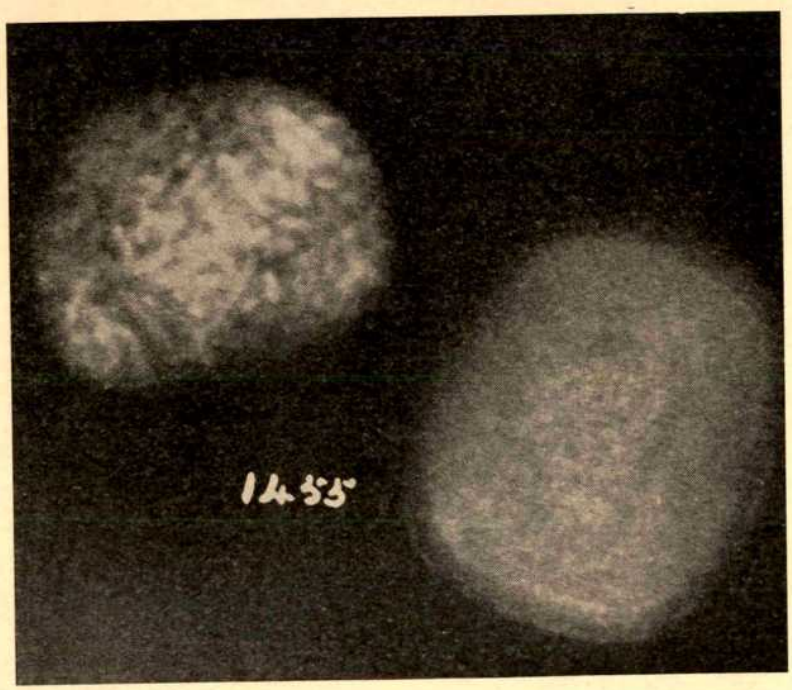

Fig. 4. Vaccinia; PTA has penetrated the particle on the right (× 160,000)

Figs. 1 and 2, showing the two types of particle observed, may be compared with Figs. 3 and 4, showing the corresponding morphological forms observed in similarly treated suspensions of vaccinia virus. Figs. 1 and 3 represent particles of virus into which the phosphotungstic acid (PTA) has failed to penetrate, the superficial beaded structure of the virus surface being clearly revealed. Enveloping membranes similar to the fragment seen in Fig. 1 are also frequently seen in vaccinia preparations. Figs. 2 and 4 show particles into which the stain has penetrated, revealing in each case a superficial 'capsule' of complex structure, surrounding a smooth inner body. Both types of particle have been reported in vaccinia virus preparations[4–6]. The details of their relationship and the significance of the fine structure observed in them will be the subject of a later communication.

In addition to the similarities in size, shape and fine structure revealed by negative staining, recent work (Fenner, F., personal communication) has demonstrated a fundamental serological relationship between the myxoma–fibroma group of viruses on one hand and the vaccinia–ectromelia group on the other. On the present evidence, therefore, the myxoma–fibroma viruses may be included with confidence as a sub-group of the pox viruses.

Synthesis of Viral Ribonucleic Acid by a Chemically Inactivated Influenza Virus

It has been shown that the fowl plague virus, which belongs to the influenza *A* group, can be inactivated by an ethylene-iminoquinone (Bayer *A* 139, a gift of the Bayer-Werke, Leverkusen, Germany)[1] or by hydroxylamine[2,3] without losing its antigenic, neuraminidase, or hæmagglutinating activities. Bayer *A* 139 mainly reacts with the phosphate groups of nucleic acids, and in this way the sugar-phosphate 'backbone' is broken[4,5]. Hydroxylamine attacks the pyrimidines of the nucleic acids without breaking the RNA-strand[6]. Since during inactivation of the fowl plague virus with both compounds a phenomenon interpreted as multiplicity reactivation was observed[1,3], one should still expect viral RNA-synthesis in cells which were infected with partially or totally inactivated virus. Experiments designed to clarify this point are described here.

The methods applied for the determination of the biological activities are described in refs. 1 and 3. The amount of viral RNA mixed with normal newly synthesized cellular RNA was calculated from the shift of the oligonucleotide pattern of the RNA labelled with phosphorus-32 after RNase digestion of infected cells towards that of viral RNA[7,8]. The synthesis of normal cellular RNA is not inhibited by infection. Viral RNA-synthesis is an additional event[7,8].

Fig. 1 shows the inactivation kinetics of fowl plague virus with Bayer *A* 139 and

hydroxylamine, which is in accordance with former results[1,3]. If the partially or totally inactivated virus samples were added to chick fibroblast tissue cultures, the results presented in Fig. 2 were obtained. While the infectivity (plaque-forming units = PFU) and, to a lesser extent, the hæmagglutination titre (HA) drop quickly with increasing time of inactivation, the yield of viral RNA stays almost constant over a relatively long time. The oligonucleotide patterns of the 18-h points are identical with those of the controls, while the total radioactivity in the RNA (18 h) is, on the average, 10 per cent lower than in the controls. The complement fixation titre (CF), which measures the amount of the *s*-antigen, shows nearly the same dependence on the inactivation time as the viral RNA.

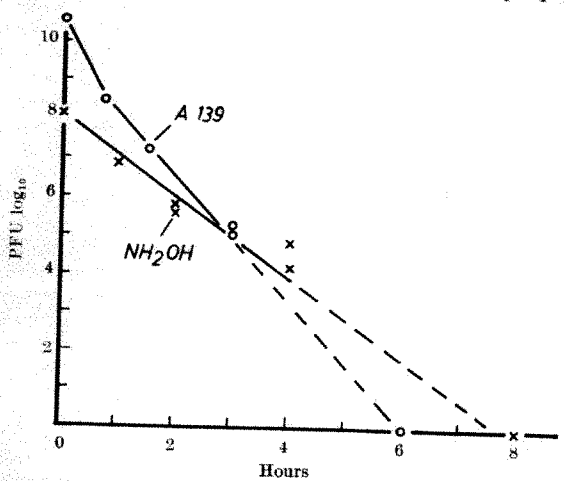

Fig. 1. Inactivation of fowl plague virus by Bayer *A* 139 and NH_2OH, respectively. Purified virus was inactivated by: (*a*) 1 per cent Bayer *A* 139 in 0·1 M *tris*-maleinate buffer *p*H 6·65; (*b*) 0·2 M NH_2OH in sodium chloride–phosphate buffer *p*H 7·0. Temperature, 21° C. For experimental details, see refs. 1 and 3. With higher inactivation it was not possible to determine the PFU exactly because of multiplicity reactivation (refs. 1 and 3). In those cases two points can be seen in the curves, which were calculated from two different dilutions

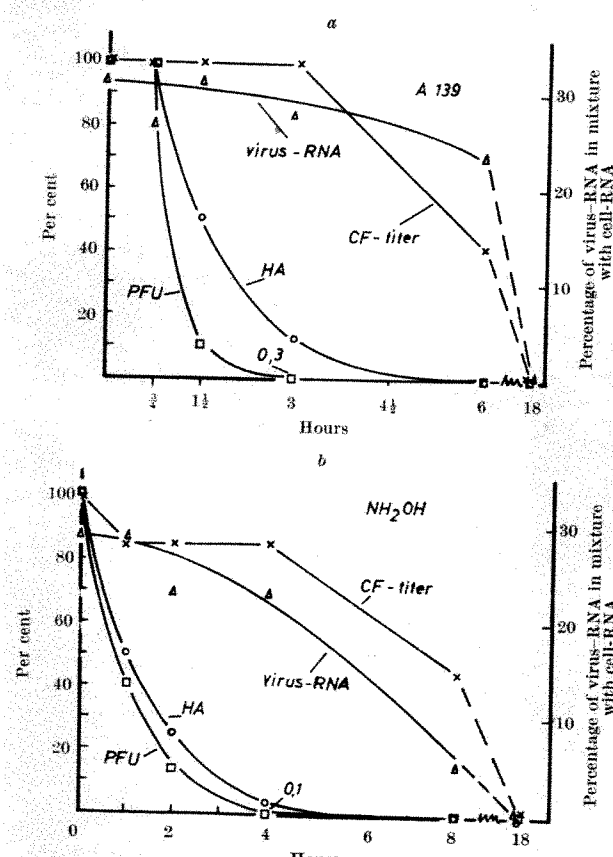

Fig. 2. Synthesis of virus-specific material in tissue cultures infected with partially or totally inactivated fowl plague virus. Chick fibroblasts were infected with virus samples inactivated by Bayer *A* 139 (*a*) or NH_2OH (*b*) for times as indicated at the abscissa of Fig. 1. On the left ordinate the percentage of these activities compared with controls infected with non-inactivated virus (= 100 per cent) is shown. The right ordinate represents the percentage of virus specific RNA in mixture with normal cellular RNA. For experimental details, see refs. 1, 3, 7 and 8

Although no material specific for this virus can be demonstrated in the infected tissue culture, if the virus is inactivated for a longer time (18 h or more), a high degree of interference has been found in these cells. Cells which were superinfected about 20 h after treatment with a virus preparation inactivated either with Bayer *A* 139 or hydroxylamine showed a virus yield 5–11 per cent of that of non-treated control cultures. This means that viral RNA-synthesis is not necessary for the interference phenomenon.

There is no significant difference between the activities of the virus samples treated for corresponding times with either Bayer *A* 139 or hydroxylamine. Therefore, it seems to make no difference whether the backbone of the nucleic acid is broken or only the pyrimidines are attacked. In both cases one has to assume that the viral RNA of the inactivated virus invades the cell and exerts there some activity even if the size of the RNA is lowered to some degree.

Prior to fowl plague viral RNA-synthesis the formation of 'early protein(s)' is necessary[8,9]. It may be that so long as that part of the virus RNA which codes for the 'early protein(s)' is not touched, the total amount of viral RNA is synthesized independently of some breaks or changes of the pyrimidines. If the total amount of the viral RNA is necessary for the formation of an infectious virus progeny, only a fraction of the virus RNA should code for the 'early protein(s)'. Because of the insensitiveness of the tests and some other uncertainties, like the relatively high multiplicity of virus particles per cell, even a rough estimate on the size of that fraction cannot be made. The hæmagglutinin has a rather complex structure of protein and carbohydrate. Therefore, it is conceivable that its formation is more sensitive to inactivation than the other activities (except PFU), which are assumed to be less complex.

We thank Prof. W. Schäfer for his interest in these experiments. This work was supported by the Deutsche Forschungsgemeinschaft.

VETERINARY SCIENCE

Concentrating Ejaculated Sperm for Electron Microscopy

In previous work on the ultrastructure of bull sperm[1] semen samples cooled on ice during transportation to the laboratory were used. These samples were centrifuged immediately after arrival, but 24–48 h usually had elapsed from time of ejaculation to time of fixation of the specimens. Since various details of several of the membrane systems of the sperm were generally rather poorly pre-

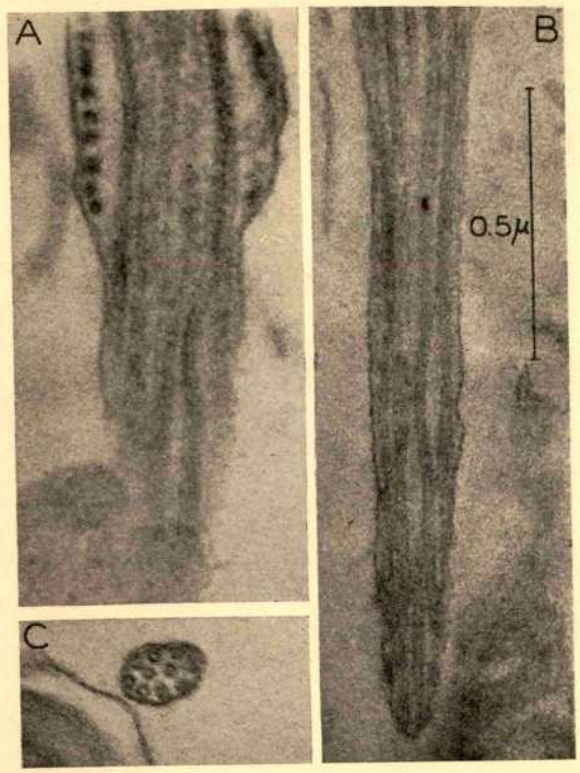

Fig. 1. *A*, Longitudinal section of the distal end of the tail of a bull sperm. The transitory region between the principal piece and the end piece of the tail is seen. Note the termination of the fibres of the fibrillar sheath, and the continuation of the intact cell membrane (lead hydroxide counter-stained, × 72,000). *B*, Longitudinal section of the very tip of the end-piece of a tail of a bull sperm. Here the central fibres (the tube fibres) are covered only by the intact cell membrane (lead hydroxide counter-stained, × 72,000). *C*, Cross-section of the end piece of the tail of a bull sperm. Only ten fibres distributed at random are present (lead hydroxide counter-stained, × 72,000)

served, subsequent centrifugations and fixations were carried out at the centre where the bulls were kept. Thus, fixation could be initiated within approximately 30 min after ejaculation. On such material, some new observations were made[2], but for optimal preservation of many delicate structures a more gentle preparative technique was obviously called for. The two factors considered to be mainly responsible for the less satisfactory results were: (1) The rather long time that had elapsed from the moment of ejaculation to the time of fixation; (2) The centrifugation for 15–20 min at 2,500–3,000 r.p.m. necessary for concentrating the sperm to a suitable number for further processing. A method which removes these two obstacles will be described.

Previously, Bloom and Nicander[3] have described a method for fixation of sperm material from the cauda epididymis. They placed drops of the concentrated sperm suspensions obtained from this source on small paper strips which were then floated on to the surface of the fixative solution. After fixation the specimen was stripped off from the surface of the paper, and cut in pieces of suitable size for dehydration and embedding.

If filter paper is used instead of ordinary paper a convenient method of concentrating ejaculated sperm for sectioning and electron microscopy is available, as a sufficient number of cells for further processing are able to penetrate into the pores of this paper. The method is simple and rapid, and at the same time a very gentle way of concentrating sperm cells prior to fixation and dehydration. The procedure is as follows:

A track is made on a piece of filter paper by drawing two parallel pencil lines 3–5 mm apart. Of a freshly ejaculated semen sample a 'smear' is obtained by distributing a few drops of semen along this track by means of a Pasteur pipette. Apparently the sperm cells are restricted to the area of the track whereas the sperm plasma is sucked into the pores of the paper beyond this track. After 2–3 min the paper has absorbed all the plasma, and a yellow-white, glossy deposit of concentrated sperm cells is left within the borders of the track. This region is now cut into strips 1 mm wide and 5–10 mm long which are quickly immersed in the fixative (2 per cent osmium with sucrose in veronal–acetate buffer $p\mathrm{H} = 7{\cdot}2$, ref. 4).

The entire procedure from receipt of ejaculate to immersion of strips in the fixative need not take more than 10 min. After fixation for the appropriate period of time dehydration and embedding of pieces of a suitable size are performed according to standard procedures. Until now embedding in 'Vestopal-*W*'[5] has been used. Sectioning of the accompanying cellulose fibres can present some difficulty, and the glass knives do wear out more rapidly than when sectioning blocks which do not contain filter paper. However, high-quality sections can be obtained, and the preservation of structural details in the sperm thus prepared is definitely superior to any we previously prepared from samples of ejaculated sperm. Perfect sections may also be obtained more easily if high-quality ash-free filter paper (for example, J. H. Munktell, Sweden, type *OOH*) is used instead of ordinary filter paper.

So far very promising results have been obtained with this method. Particularly the cell membrane and other membranous structures of the sperm seem to be better preserved than hitherto. This is illustrated in the accompanying Fig. 1 in which an intact cell membrane at the very tip of the end piece of the tail (the end piece of Retzius) as well as in the transitory region between principal piece and end piece is shown. Fig. 2 shows well-

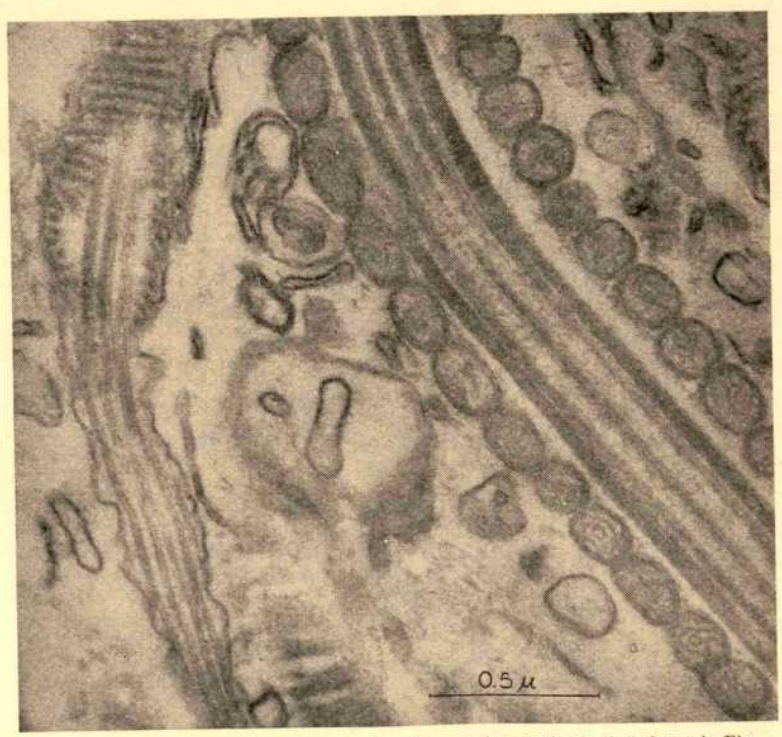

Fig. 2. Left, a longitudinal section of a transitory region similar to that shown in Fig. 1*A*; right, longitudinal section through the middle piece of a bull sperm. Note the mitochondrial helix with well-preserved inner membranes (cristæ). Between the cells several circular profiles of laminated structures and some membrane fragments are pictured. These structures are the contents of the cytoplasmic droplets normally disposed of by the sperm during ejaculation (uranyl acetate counter-stained, × 46,000)

preserved inner membranes or cristæ in the mitochondrial helix of the middle piece of the tail. These structures are generally very difficult to obtain in a well-preserved state in ejaculated sperm. The same applies to various membranous structures in the head of the sperm as well as in the so-called implantation region between head and tail. In these latter cases also, the filter-paper method has proved superior to other previously used methods. Finally, it should be mentioned that this method of concentration is less selective than centrifugation. Sections of material prepared by the new method contain a great number of circular, laminated profiles between the sperm cells. These structures can easily be identified as the characteristic contents of the cytoplasmic droplets (distal droplets) which the sperm cells normally dispose of during the ejaculation process. These profiles are always left in the supernate, and consequently lost when the sperm are concentrated by means of centrifugation.

We thank Mr. Hans Philipsen, chief veterinary officer, Ringsted, Denmark, for his assistance in supplying the samples of bull semen.

PSYCHIATRY

3,4-Dimethoxyphenylethylamine and Other Amines in the Urine of Schizophrenic Patients

Friedhoff and Van Winkle[1] have reported the presence of 3,4-dimethoxyphenylethylamine in urine from 15 of 19 schizophrenic patients while there was none in urine from 14 normal subjects. Because of the clear biochemical difference between both groups and the structural resemblance of the amine with mescaline, it was considered to be important to confirm their results in a different laboratory. The urine amines were examined first according to their method; but resolution of compounds was not satisfactory on the paper chromatograms and several compounds having similar R_F values interfered with the identification of 3,4-dimethoxyphenylethylamine. Therefore, an improved method was devised in order to obtain a better chromatogram of the amines.

An amount of urine containing 50 mg creatinine was acidified to *p*H 2 by the addition of concentrated hydrochloric acid and heated in boiling water for 30 min. Initial purification of the amines was carried out with a modification of the method used by one of us[2] for the purification of urinary phenolic amines: A column (1 × 4 cm) of 'Dowex 50 (H^+)' was used for the collection of amines and the column was washed with 10 ml. of 0·1 N sodium acetate and 10 ml. of water successively. Amines were eluted with 8 ml. of the ammoniacal ethanol. The eluate was evaporated to dryness in a vacuum desiccator over sulphuric acid, and the residue was dissolved in 1 ml. of 0·1 N sodium borate buffer *p*H 9. The solution was shaken with 5 ml. of chloroform and the organic layer was evaporated in a stream of air at room temperature. The dried residue was dissolved in a few drops of ethanol and subjected to two-dimensional paper chromatography with the solvent systems previously used for phenolic amines[2]. The compounds were visualized with ninhydrin reagent[1]. The recovery of authentic 3,4-dimethoxyphenylethylamine added to urine which was then subjected to the procedures was about 90 per cent. Resolution of the amines on the chromatogram was satisfactory and many interfering substances were eliminated by the purification procedures. The spots observed frequently on the paper chromatograms are shown in Fig. 1. The compounds were identified by co-chromatography of authentic compounds with those from urine, and by several qualitative reactions.

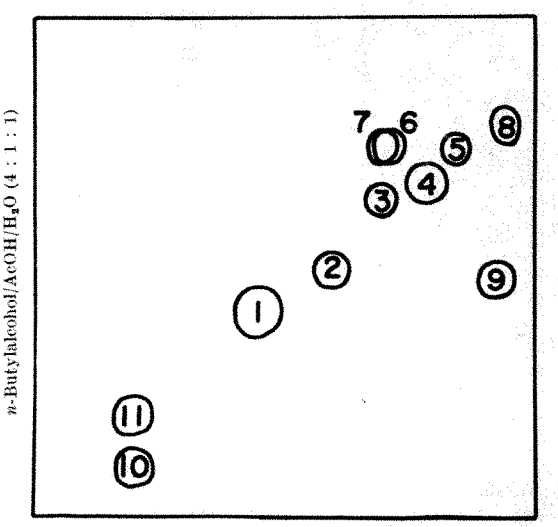

Fig. 1. Paper chromatogram of amines prepared from human urine with the methods described in the text. Tentatively identified compounds are threamine (2), 3-methoxytyramine (3), *p*-tyramine (4), 3,4-dimethoxyphenylethylamine (5) and 10-(3-aminopropyl)-2-chloro-5-oxyphenothiazine (6). The numbers in parentheses correspond to the numbers in the figure

Urine specimens were obtained from 78 schizophrenic patients, 21 psychoneurotic patients and 46 normal subjects. Of the 78 schizophrenics, 16 patients were under treatment with psychotropic drugs, usually chlorpromazine, and the other 62 patients had not received any medications for a minimum period of three weeks before they were studied. About half the schizophrenics had been sent to hospital. Normal controls were selected from the hospital staff and their families so that the sex and age distributions matched those of the patients. The frequency of the occurrence of 3,4-dimethoxyphenylethylamine in urine is listed for each group in Table 1.

Table 1. APPEARANCE OF 3,4-DIMETHOXYPHENYLETHYLAMINE IN URINE

	No. examined	Frequency of appearance of 3,4-dimethoxyphenylethylamine
Normal subjects	46	21/46
Psychoneurotics	21	14/21
Schizophrenics under no medication	62	57/62
Schizophrenics under drug therapy	16	13/16

Although the frequency of the appearance is higher in urine of schizophrenics than in normal subjects, the occurrence of the amine in urine is not so specific to schizophrenia as shown by Friedhoff and Van Winkle. Moreover, the concentrations of the other amines were observed to be generally higher in the urine of schizophrenics, which might explain the higher frequency of the appearance in urine of schizophrenics. It may be recalled that, in general, larger amounts of aromatic acids, particularly the *m*-hydroxyphenyl acids, are observed in urine from schizophrenics as compared with normal controls[3,4].

As suggested by Friedhoff and Van Winkle, 3,4-dimethoxyphenylethylamine might be a metabolite of dopamine. This possibility was examined with negative results as follows. The amount of 3,4-dimethoxyphenyl-

ethylamine in the urine of two normal subjects did not increase after oral administration of 0·5 g of 3,4-dihydroxy-L-phenylalanine and the amine could not be detected in the urine of two patients with pheochromocytoma. In urine of three groups of five rats each given intramuscular injections of 3,4-hydroxy-L-phenylalanine (100 mg/kg body-wt.), dopamine (10 mg/kg) and norepinephrine (1 mg/kg) respectively, 3,4-dimethoxyphenylethylamine could not be detected. Considering the chemical structure of the amine, an endogenous precursor would probably be either dopamine or 3-methoxytyramine. A large amount of the latter compound was consistently detected in urine from both human subjects and rats after the administration of either 3,4-dihydroxy-L-phenylalanine or dopamine. These results imply that 3,4-dimethoxyphenylethylamine originates from dietary sources or is a product formed by intestinal bacteria.

An amine indicated as No. 6 in Fig. 1 was frequently observed on the chromatograms of urine from schizophrenic patients who had received chlorpromazine. It was purified by a combination of ion exchange chromatography and counter current distribution techniques, and was tentatively identified as 10-(3-aminopropyl)-2-chloro-5-oxyphenothiazine from the results of elemental analysis, infra-red and ultra-violet absorption spectra. The occurrence of this compound in human urine as a metabolite of chlorpromazine was reported by Fishman and Goldenberg[5].

It is of interest that another unidentified compound (Fig. 1, No. 7) was observed more frequently in the urine of schizophrenics (25/62) than in the urine of normal subjects (2/21) and psychoneurotics (2/21). This substance was detected as a purple spot with ninhydrin reaction and did not react with any of several other reagents. This compound might also originate from dietary sources because the amount excreted daily varied widely. It should be mentioned that the R_F value of this amine is similar to that of 3,4-dimethoxyphenylethylamine in the first solvent system, which is the system used by Friedhoff and Van Winkle. Therefore, the metabolite of chlorpromazine and the other unidentified substance might be confused with 3,4-dimethoxyphenylethylamine. The other amines numbered 1–4 in Fig. 1 were observed in all specimens of urine and the amines numbered 8–11 were detected frequently.

The preceding communication confirming the presence of 3,4-dimethoxyphenylethylamine in the urine of schizophrenic patients[1,2] is of considerable interest. The fact that their procedure differed in some respects from ours adds further support to our identification of this compound.

It should be pointed out that interfering compounds have been described by us. We have sometimes found it necessary to resolve 3,4-dimethoxyphenylethylamine by the use of 2 successive solvents. Several satisfactory solvent systems are described in our publications. In general, however, 3,4-dimethoxyphenylethylamine can be distinguished from other chromatographically similar compounds by means of the specific colour reaction for β-phenylethylamines that we have developed[3].

The results of Takesada *et al.* are particularly impressive because of the unusually high percentage of schizophrenic patients who excrete identifiable 3,4-dimethoxyphenylethylamine. Their incidence is higher than that found in our group of patients. This suggests either that their methods are more sensitive than ours or that their diagnostic classification or patient population is somewhat different from ours.

Their detection of 3,4-dimethoxyphenylethylamine in the urine obtained from a normal control group may have resulted from the increased sensitivity of their analytical methods, but it is pertinent that our normal controls were selected with deliberate intention to exclude any subjects with even mild schizoid tendencies. If schizophrenia is a genetically determined disorder, it would be expected that a significant percentage of the 'normal' population would have incomplete penetrance of the disease. It would seem, therefore, to be crucial not only to do qualitative studies but also quantitative determinations of 3,4-dimethoxyphenylethylamine in normal subjects and patients. Also, a specific comparison of patients according to diagnostic criteria should be carried out inasmuch as some cases of schizophrenia in one country would be classified as psychoneuroses in another.

The attempt to synthesize 3,4-dimethoxyphenylethylamine from dihydroxyphenylalanine and dopamine carried out by Takesada *et al.* did not result in the formation of the dimethoxy amine. It should be pointed out that the conversion rate of infused precursors of this compound may be very low. In any event, it seems most fruitful to examine this conversion in schizophrenic patients where the conversion is most likely to occur. Inasmuch as rats do not appear to excrete 3,4-dimethoxyphenylethylamine, it is unlikely that they would form it from precursors. We are now carrying out investigations in schizophrenic patients using tritiated dopamine as a precursor.

The data of Takesada *et al.*, when subjected to simple χ^2 analysis, reveal that their combined schizophrenic group differs significantly from their normal control group ($P < 0{\cdot}001$) in the incidence of 3,4-dimethoxyphenylethylamine in urine. This finding alone plus the pharmacological nature of 3,4-dimethoxyphenylethylamine suggest that many additional investigations of this compound should be carried out. It is of uncommon interest that 3,4-dimethoxyphenylethylamine has profound central effects without appreciable peripheral effect[4]. This is compatible with the symptoms characterizing schizophrenia. In addition, 3,4-dimethoxyphenylethylamine has been shown to produce experimental catatonia in cats[5,6].

Takesada *et al.* have confirmed the presence of a potentially psychotoxic compound in urine. They suggest that this compound is of dietary or microbial origin, but they provide no data to support this.

We feel that considerable caution should be exercised in the interpretation of the relationship of 3,4-dimethoxyphenylethylamine to schizophrenia. At the present time, therefore, it must be concluded that the origin and significance of this compound has not been ascertained. The unusually high incidence of 3,4-dimethoxyphenylethylamine in the urine of the patients studied by Takesada *et al.* should stimulate further interest in investigating the possible significance of this compound in mental illness.

FORTHCOMING EVENTS

(Meeting marked with an asterisk is open to the public)

Wednesday, July 17—Tuesday, July 23

FIFTH INTERNATIONAL PESTICIDES CONGRESS (at Friends House, Euston Road, London, N.W.1).

Thursday, July 18

COUNCIL FOR THE PRESERVATION OF RURAL ENGLAND (at the Royal Institute of British Architects, 66 Portland Place, London, W.1), at 2.30 p.m. —Annual General Meeting. Address by the Rt. Hon. Viscount Colville of Culross.

Friday, July 19

IMPERIAL COLLEGE OF TROPICAL AGRICULTURE, U.K. ASSOCIATION (at Uganda House, Trafalgar Square, London, W.C.2), at 2.45 p.m.—Dr. Harry Evans, O.B.E.: "The Practical Application of Scientific Procedures for the Improvement of Agricultural Productivity in British Guiana".*

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ASSISTANT LECTURER (with a degree in agriculture or equivalent qualification, sound experience in practical farming, and preferably previous teaching experience) IN AGRICULTURE at the Cumberland and Westmorland Farm School, Newton Rigg, near Penrith, and for lecturing, demonstration and advisory work in the two Counties—The Director of Education, 5 Portland Square, Carlisle (July 18).

ASSISTANT LECTURERS or COLLEGE LECTURERS (2) (preferably with special qualifications in pure mathematics, and experience as a lecturer or teacher)—The Secretary and Bursar, University College, Dublin, Republic of Ireland (July 20).

LECTURER IN PSYCHIATRY—The Registrar, The University, Sheffield (July 20).

LECTURER or SENIOR LECTURER IN SOCIAL GEOGRAPHY—The Registrar, The University, Keele, Staffs (July 20).

RESEARCH ASSISTANT IN ELECTROCHEMISTRY, to work with a group developing the study of the kinetics of organic electrochemical reactions and of new techniques for electrochemical synthesis—Head of the School of Chemistry, King's College (University of Durham), Newcastle upon Tyne 1 (July 20).

RESEARCH ASSISTANT (preferably with experience in the interpretation of air-photos, and a degree in geography) IN THE GEOGRAPHY DEPARTMENT, to work on the organization and classification of a vast library of air-photos, mostly of parts of Europe—The Registrar, The University, Keele, Staffs (July 20).

RESEARCH ASSISTANT (trained research worker) IN THE DEPARTMENT OF PHYSICAL CHEMISTRY, to work with a group developing the study of the kinetics of organic electrochemical reactions and of new techniques for electrochemical synthesis—Head of the School of Chemistry, King's College (University of Durham), Newcastle upon Tyne 1 (July 20).

SECOND CHAIR OF CHEMICAL ENGINEERING—Registrar and Secretary, King's College (University of Durham), Newcastle upon Tyne (July 20).

LECTURER (preferably with a medical qualification) IN THE DEPARTMENT OF PHARMACOLOGY—The Secretary, The Welsh National School of Medicine, (University of Wales), 34 Newport Road, Cardiff (July 22).

RESEARCH WORKER (with a good honours degree, not necessarily in psychology) IN THE DEPARTMENT OF PSYCHOLOGY, for work in the field of programmed instruction—The Registrar, The University, Sheffield (July 22).

ASSISTANT LECTURER (preferably cellular biochemist or physiologist) IN ZOOLOGY—The Secretary, The University, Aberdeen (July 24).

ASSISTANT LECTURER IN PHYSIOLOGICAL CHEMISTRY—The Registrar (Room 22, O.R.B.), The University, Reading (July 27).

COMPUTER OFFICER IN THE SUB-DEPARTMENT OF NUMERICAL ANALYSIS in the Department of Applied Mathematics—The Registrar, The University, Liverpool, quoting Ref. No. CV/354 (July 27).

LECTURER (graduate interested in the quantitative husbandry aspects of farm management, and with qualifications or experience in statistics or mathematics) IN AGRICULTURE—The Registrar (Room 22, O.R.B), The University, Reading (July 27).

PROFESSOR OF ANIMAL HUSBANDRY AND HEAD OF THE DEPARTMENT OF ANIMAL PRODUCTION; PROFESSOR OF TROPICAL CROPS AND HEAD OF THE DEPARTMENT OF CROP PRODUCTION, and LECTURER or SENIOR LECTURER IN GENETICS AND PLANT BREEDING IN THE FACULTY OF AGRICULTURE, Kwame Nkrumah University of Science and Technology, Kumasi, Ghana—The Assistant Registrar, Kwame Nkrumah University of Science and Technology, 15 Gordon Square, London, W.C.1 (July 29).

HISTOCHEMIST and a TUMOUR IMMUNOLOGIST (medical or non-medical graduates), for work concerning certain aspects of induced mammary tumours (encouragement will also be given to develop other lines of research) —The Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London, W.C.2 (July 31).

JUNIOR RESEARCH FELLOW IN BOTANY—The Registrar, The University, Sheffield (July 31).

RESEARCH SCIENTIST (with a background in any of the geological, biological, chemical or physical sciences), to initiate and carry out an electron microscopic study of ultra-microscopic organisms in sedimentary rocks in the Sedimentary Research Laboratory, Department of Geology—Prof. P. Allen, Sedimentary Research Laboratory, The University, Whitenights Park, Reading (July 31).

RESEARCH STUDENT (with a good honours degree or equivalent in chemistry, physics or geology) IN THE DEPARTMENT OF CHEMISTRY, to work on the crystal structure of zeolites, using electron microscopy and diffraction techniques—Prof. G. M. Burnett, Department of Chemistry, The University, Old Aberdeen (July 31).

SCIENTIFIC OFFICER (with a first- or second-class honours degree) IN THE BIOCHEMISTRY DEPARTMENT, to assist in research on the chemistry and biochemistry of casein—The Secretary, The Hannah Dairy Research Institute, Ayr, Scotland (July 31).

SENIOR LECTURER IN CLINICAL GENETICS tenable conjointly at University College Hospital Medical School and University College, for research in human genetics, under the direction of Profs. M. L. Rosenheim and L. S. Penrose—The Secretary, University College, Gower Street, London, W.C.1 (July 31).

UNIVERSITY DEMONSTRATOR IN INORGANIC CHEMISTRY—Dr. F. B. Kipping, University Chemical Laboratory, Lensfield, Cambridge (July 31).

UNIVERSITY DEMONSTRATOR IN THE DEPARTMENT OF PHYSICS—The Secretary of the Appointments Committee of the Faculty of Physics and Chemistry, The University, Lensfield Road, Cambridge (July 31).

STATISTICIAN (Senior Scientific Officer or Principal Scientific Officer grade) as HEAD OF THE DEPARTMENT OF BIOMETRICS—The Secretary, The Grassland Research Institute, Hurley, Maidenhead, Berks (August 1).

PLANT PHYSIOLOGIST (Senior Research Officer or Principal Research Officer) (with a Ph.D. degree in plant physiology or biochemistry, or postgraduate research experience of an equivalent standard and duration supported by satisfactory evidence of research ability, and research experience in post-harvest physiology) IN THE DIVISION OF FOOD PRESERVATION, Commonwealth Scientific and Industrial Research Organization, Ryde, New South Wales, Australia, to take a leading part in the development of research on the physiology of fruits after harvesting, especially in relation to disorders occurring during ripening and storage—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 300/368 (August 3).

LECTURERS or ASSISTANT LECTURERS (3) IN PHYSICS at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (August 8).

CHAIR OF AGRICULTURE at the University of Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (August 10).

LECTURER or ASSISTANT LECTURER IN ANIMAL HUSBANDRY at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (August 10).

LECTURER or ASSISTANT LECTURER (with an honours degree in botany or agricultural botany with a special interest in plant physiology, and preferably with experience of university teaching and/or research) IN AGRICULTURAL BOTANY at Makerere University, East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (August 10).

VETERINARY PARASITOLOGIST (with a degree in veterinary science or equivalent qualifications, with postgraduate field experience, preferably in parasitology), at the Animal Health Research Laboratory, Commonwealth Scientific and Industrial Research Organization, Melbourne, Australia, to assist in investigations of helminth infections in sheep in southern Australia in collaboration, when necessary, with the staff of the McMaster Laboratory, Sydney—Chief Scientific Liaison Officer, Australia Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 201/190 (August 10).

ANIMAL HUSBANDRY OFFICER; and an ANIMAL NUTRITION CHEMIST in the Institute for Agricultural Research at Samaru (Ahmadu Bello University, Northern Nigeria)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (August 14).

SENIOR LECTURER or LECTURER IN GEOGRAPHY at Fourah Bay College, The University College of Sierra Leone—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (August 14).

CHAIR OF MATHEMATICS at the University of Ife, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (August 15).

LECTURER/ASSISTANT LECTURER (with at least a good honours degree, suitable teaching and research experience, special qualifications in angiosperm taxonomy, and an enthusiastic field worker) IN THE DEPARTMENT OF BOTANY in the Faculty of Science, University of Malaya—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Malaya and London, August 15).

SENIOR LECTURER, and a LECTURER (preferably with qualifications in one or more of the following fields: educational psychology, educational sociology, educational statistics, or science education) IN EDUCATION at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 16).

LECTURER (preferably with a special interest in electronics) IN APPLIED PHYSICS—The Registrar and Secretary, Durham Colleges in the University of Durham, 38 North Bailey, Durham (August 17).

SENIOR LECTURER or LECTURER IN THERAPEUTICS in the Department of Materia Medica and Therapeutics—The Secretary, The University, Aberdeen (August 17).

READER IN ORAL MEDICINE AND PATHOLOGY at the London Hospital Medical College—The Academic Registrar, University of London, Senate House, London, W.C.1 (August 22).

SENIOR LECTURER (with a doctorate in social and/or cultural anthropology, and some teaching and field experience) IN THE DEPARTMENT OF ANTHROPOLOGY, University of Western Australia—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 24).

SENIOR LECTURER or LECTURER IN THE DEPARTMENT OF OPHTHALMOLOGY, University of Ibadan, Nigeria—The Secretary, Senate Committee on Colleges Overseas in Special Relation, University of London, Senate House, London, W.C.1 (August 26).

RESEARCH ASSISTANT (with experience in embryology and/or biophysics) IN THE DEPARTMENT OF ZOOLOGY, for work on the effect of drugs on the uptake and distribution of water in the developing embryo—Dr. P. H. Tuft, Department of Zoology, University of Edinburgh, West Mains Road, Edinburgh (September 2).

CHAIR OF GEOLOGY at the University of Malaya—The Secretary, Association of Universities of the British Commonwealth (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Kuala Lumpur and London, September 30).

SENIOR RESEARCH FELLOW (with a Ph.D. degree or equivalent qualification, or a distinguished record of scientific research), for research at the Forest Research Institute of the New Zealand Forest Service—The Director of Research, Forest Research Institute, Private Bag, Whakarewarewa, Rotorua, New Zealand (November 30).

ANALYTICAL CHEMIST (Soils) (under 45, with a good honours degree in an appropriate subject, and experienced in soil survey and land use planning) in Eastern Nigeria, to carry out, with Soil Surveyors, a soil survey of the sites for development as settlements and institutes—The Director of Recruitment, Department of Technical Co-operation, Great Smith Street, London, S.W.1, quoting RC.213/103/01.

ASSISTANT CONSERVATOR OF FORESTS (aged between 20–45, with a degree in forestry, and preferably previous experience in South-East Asia and/or a knowledge of the Malay language) IN THE DEPARTMENT OF FORESTS, Sarawak, for general forest administration—The Director of Recruitment,

Department of Technical Co-operation, Great Smith Street, London, S.W.1, quoting Ref. TRC324/128/01.

Assistant Lecturer (with an honours degree and industrial experience, and preferably a qualification in telecommunications) in the Department of Electrical and Control Engineering—Clerk to the Governing Body, Battersea College of Technology, London, S.W.11.

Head (with good academic qualifications with teaching and/or industrial experience, and able to organize research in the department) of the Electrical Engineering Department—Clerk to the Governors, Woolwich Polytechnic, London, S.E.18.

Nematologist (male, with an honours degree in zoology or entomology and at least one year's postgraduate training or experience, preferably in the study of nematodes) in the Ministry of Agriculture, Uganda, to undertake a survey of the occurrence of harmful nematodes on crops; to develop techniques for testing host reactions and for controlling nematodes of economic importance—The Director of Recruitment, Department of Technical Co-operation, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting Rev. CI/RC.213/153/07.

Oil Palm Agronomist (between 26 and 45 years of age, with a degree in agriculture or natural science, followed by two years postgraduate training, and experience on an Oil Palm Research Station as an Agronomist) in North Borneo, to deal with the general agronomics and detailed field experimentation of oil palms in North Borneo and in particular at the Oil Palm Research Station—The Director of Recruitment, Department of Technical Co-operation, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting Ref. T/RC.213/107/04.

Publications Officer (preferably male or female graduate with some knowledge of languages), to be responsible for the publication of research papers, reports and the quarterly journal—The Director, The British Ceramic Research Association, Queens Road, Penkhull, Stoke-on-Trent.

Radioisotope Officer (with an honours degree in chemistry or physics and experience of the use of radioisotopes as tracers in biological research), to supervise all work with radioisotopes and collaborate with other officers in research on diseases of farm animals—The Secretary, Animal Diseases Research Association, Moredun Institute, Gilmerton, Edinburgh 9.

Research Assistant (competent in quantitative chemical analysis and an interest in animal physiology), for various types of biological research, mainly biochemical in character, together with some preparation of material for advanced classes—The Administrator, University Laboratory of Physiology, Oxford.

Research Assistant, for work on the biochemistry of migraine—The Secretary, Institute of Neurology, The National Hospital, Queen Square, London, W.C.1.

Research Biochemist in the Department of Physiology, to work upon the isolation of radioactively labelled carbohydrates and derivatives in tissues (animal)—Prof. A. St. G. Huggett, St. Mary's Hospital Medical School, Paddington, London, W.2.

Scientific Officer for Microbiological Assay Unit (Vitamin B12 and Folic Acid)—The Hospital Secretary, City General Hospital, Sheffield 5.

Senior Technicians and Technicians, for general duties in the physics laboratories to assist with research, lecture preparation and photography—Professor of Experimental Physics, Physics Laboratory, University of Sussex, Falmer, Sussex.

Smith and Nephew Research Fellow (preferably with research experience in the field of protein biosynthesis) in the Empire Rheumatism Council Research Unit at King's College Hospital Medical School—Dr. M. J. H. Smith, Chemical Pathology Department, King's College Hospital Medical School, Denmark Hill, London, S.E.5.

Superintendent (with a degree in biological science or equivalent qualification, for example, F.A.T.A., and experience in some branch of animal work) to take charge of the Physiology Department's goat and small animal houses—The Secretary, National Institute for Research in Dairying, Shinfield, Reading, Berks, quoting Ref. 63/2.

Technician (Male) in the Department of Anatomy—Prof. D. V. Davies, Anatomy Department, St. Thomas's Hospital Medical School, London, S.E.1.

Technicians (2) (preferably with experience in a hospital laboratory) in the Biochemistry Department, for work largely of a clinical nature, but including participation in research projects—J. S. Leahy, Huntingdon Research Centre, Huntingdon.

ORGANIZING SCIENTIFIC AND INDUSTRIAL RESEARCH IN BRITAIN

THE report of the Council for Scientific and Industrial Research for 1962* records a year of continued expansion in which gross expenditure for the year ended March 31, 1962, was almost £2·25 million above the gross expenditure of £14·5 million in 1961–62, while further expansion is contemplated in the near future. This growing effort of the Department in industrial research, like the Government's programme of expansion in technical and higher education, is related to the objectives referred to by the National Economic Development Council in its recent report *Conditions Favourable to Faster Growth* (*Nature*, 198, 1123; 1963), as the Parliamentary Secretary for Science said in the House of Commons on May 28. On that occasion Mr. Freeth also said that the Research Council was to consider further the section of the latter report relating to the extension of the use of civil development contracts to industry and to co-operation between Government and industry. According to the report of the National Economic Development Council, the Council for Scientific and Industrial Research has already suggested that Government and industry should co-operate to identify promising fields for research and development. Recognizing the importance of the scale of Britain's research and development effort being appropriate to the needs of the programme for growth, the National Economic Development Council has undertaken to examine and consider these various matters together with other related questions. Included would be the supply of technicians and scientific manpower generally, the contribution which the social sciences could make and the effective integration in civil industry of any patented benefits from defence research.

It could not have been expected that in its present report the Council for Industrial and Scientific Research could make more than passing reference to its consultation with the National Economic Development Council, but it is curious that although the report discusses two general aspects of expansion which are mentioned in *Conditions Favourable to Faster Growth* the National Economic Development Council is not mentioned. Of the first of these matters, that of establishing the right priorities since there are always new ideas for research competing with one another and with the work in hand for limited resources, the Research Council observes that it must take the initiative in establishing these priorities so that no important research project or programme is neglected. Hence, the research effort on behalf of different industries and in different scientific disciplines is brought into balance. Secondly, the Research Council comments on the extent to which, as the part played by science in national life grows and research and development become more complex, more organizations are concerned with the planning, execution and application of research, it is called on to play a part in the necessary co-ordination.

These twin functions of co-ordination and initiation serve two main purposes: they ensure that the whole research field is covered without overlap, and they present a coherent scientific picture as a basis for executive decisions. Obviously, the Council for Scientific and Industrial Research has a vital part to play in both functions, but it is a limited part. The other Research Councils have their own contribution to make, but the major responsibility for co-cordination surely rests with the Advisory Council for Scientific Policy.

These two functions, as they affect co-operation within the Government, with industry and with universities and colleges, are discussed in the opening part of the Research Council's report, which represents the main contribution of the report to the discussion of industrial research and development generally. Reference is also made to: (1) the completion by the Economics Committee of studies of the marine engineering industry in the United Kingdom and of research and development in foundry engineering and equipment; (2) the approval of arrangements with the Manchester College of Science and Technology for the study of the structure and economy of the building industry; (3) the establishment, in May 1962, of the committee to consider the present standing of mechanical engineering design in relation to the United Kingdom engineering industry and practice overseas, and to recommend any changes likely to result in improved design of British products. Comment on the work of the Department's own research stations is limited to that of the Building Research Station, the programme of space research at the Radio Research Station, the National Physical Laboratory on standards of measurement, the Government Chemist's Laboratory on the fluoridation of water supplies, the Forest Products Research Laboratory on the stress grading of timber, and the Torry Research Station on the quick freezing and low-temperature storage of fish at sea. The position of the research stations in relation to research and development generally is not considered, and the paragraphs dealing with the research associations likewise—apart from a reference to foreign membership of the associations—do not refer to general problems. The work of the Information Services is discussed in a page and a half, and the international activities and responsibilities of the Department are described in another two pages.

Apart from the Information Services, reports are published separately by most, if not all, of the research stations and research associations supported by the Department. With the further reports covering the Department's support of universities and colleges by research grants and training awards and on the research associations as a whole, it is understandable that the Council's own annual report should no longer deal in any detail with these individual activities. That, however, makes it the more desirable that the Council's own report should be careful to fill any lacuna in these other reports.

There is, in fact, a brief comment on the report of the Gibb–Zuckerman Committee on the management and control of research and development, in which the Research Council reaffirms its belief in the value of a steering committee as a normal feature in running a research establishment contrary to the view of the Gibb–Zuckerman Committee. However, two notable omissions are the absence of any discussion of the Department's responsibilities in regard to overseas research or any indication that the suggestions advanced at the British Association for the Advancement of Science meeting last September regarding the reorganization of research along technological lines

* Department of Scientific and Industrial Research. Report of the Research Council for the Year 1962. Pp. 62. (Cmnd. 2027.) (London: H.M.S.O., 1963.) 4*s*. net. (See also p. 233 of this issue of *Nature*.)

rather than that of individual industries are being examined (see *Nature*, 197, 222; 199, 106; 1963). Concerning the latter, despite the obvious inherent practical difficulties of the suggestion made by Mr. L. Holliday, it offers possible advantages that might well be worth the effort. It would have been encouraging to find evidence in this report that the Research Council was aware of such new potentialities and prepared to explore them. With its silence in regard to overseas research and to the National Economic Development Council, the present report is disturbing. If not exactly dragging its feet, the Research Council is not so alert as it might be and may be missing opportunities.

Nevertheless, much of the report is unexceptional. The Research Council aims to take a more positive part in the influence which science exerts on the operations of government, seeking to anticipate, so far as possible, the questions to which practical answers will be needed. The leading part played by the Department of Scientific and Industrial Research in the study of the medical and meteorological aspects, as well as the physical and chemical aspects is instanced as one example. Since 1955 an inter-departmental committee of which the Department provides the chairman, and, including representatives from the appropriate executive department and the Ministry of Housing and Local Government, has co-ordinated the whole subject. Water supplies are a further example, and while for many years the Geological Survey and Museum has been co-operating closely with the Ministry of Housing and Local Government in this field, a Hydrological Research Committee has now been set up to perform a co-ordinating function parallel to that of the inter-departmental committee on air pollution research.

Again, in co-operation with the Ministry of Health, the Research Council has recently established a Committee for Research on Dental Materials and Equipment to investigate the use of materials of greater strength and other improved physical properties which could offer considerable savings in conservative and prosthetic dentistry. Besides the Ministry of Health and the Department, the Medical Research Council is represented on the Committee, which also includes prominent academic and other research workers in this field. Care is also taken, through a Committee established in 1945, for which the Department provides a chairman and secretariat, and of which the Chairman of the University Grants Committee is a member, to ensure that each Department placing research contracts with universities is informed of contracts placed by all other Departments, so that all the contracts are placed on similar terms and there is no overlapping or duplication. This Committee is thus well placed to see that the proposed researches do not distort the pattern of university research.

All this organization must clearly be considered in any review of the structure of civil research, and there can be little doubt that while the Council for Scientific and Industrial Research has not the range of responsibility of the Advisory Council for Scientific Policy, it plays a much larger part than the other Research Councils. In co-operation with industry, the Department is, of course, a natural instrument, and while the pattern of co-operation varies, the Department appears to be functioning effectively. A steering committee has now been established, on which industry is represented, to guide co-operation in industry and Government laboratories in research and development in computers, and the report also cites an instance in research into methods of automation. An experimental project at the Parc Mine, near Llanwrst, North Wales, seeks to provide the basic data for the automatic control of mineral processing, notably the separation of valuable minerals from naturally occurring ores, and it should also indicate whether existing machinery, instruments and control equipment are suitable for use in automatically controlled, continuously operating plants.

As regards co-operation with universities and colleges, the Council of Scientific and Industrial Research observes that it is increasingly required to consider carefully how funds should be allotted between and within the scientific disciplines, and, in particular, what steps are necessary to ensure that neglected subjects are duly encouraged. It is, of course, in this connexion that Mr. Holliday's suggestion regarding the interaction of technologies and the concentration of research associations is important. In its present report, the Council expresses its view that more fundamental and technological research on engineering materials should be encouraged, and it instances the fundamental study of brittle fracture of which the Department is to act as the focal part, and the establishment by its Research Grants Committee of a new Sub-committee in Metallurgy and Materials. A Machine-Tool Research Co-ordinating Committee has also been set up, on which are represented the main laboratories in which the Department is financing research in this field.

The Council's latest report thus amply illustrates the widespread ramifications of the work of the Department of Scientific and Industrial Research and the key position which the Council occupies in the structure of Britain's civil research effort. If the report no longer supplies the conspectus of that work which earlier reports used to do that is almost inevitable, and provided that such reports as *Research for Industry* (*Nature*, 196, 97, 115; 1962) and the reviews of the Department's support for universities and colleges are comprehensive and up to date, that need not be material. It is, however, essential that the Council should ensure that all aspects of the Department's work are adequately carved in some such way and that it should be alert not only to see that its own report makes good any unavoidable gaps in the current year but also that any lack of prospective is corrected. Further, relieved, and justifiably so, from reporting on much detail, it is reasonable to expect that the Council should be concerned in its own report not merely to supply that wider perspective but also the forward look and especially to see that the significance of present-day developments is brought out to the fullest possible extent. It is in these respects that the present report falls short of what might have been expected.

NUCLEAR RESEARCH REACTORS

Programming and Utilization of Research Reactors

Proceedings of a Symposium held in Vienna, October 16–21, 1961. Vol. 1. Pp. xvi + 328. Vol. 2. Pp. xviii + 528. (London and New York: Academic Press. Published for the International Atomic Energy Agency, 1962.) Vol. 1, 63*s*.; Vol. 2, 105*s*.

AT the 1955 Geneva Conference on the Peaceful Uses of Atomic Energy most nations of the world presented statements of their possible needs for nuclear energy in the decades ahead, and many indicated the

great educational effort which would have to be devoted to training in nuclear science and engineering to prepare their countries for the advent of nuclear power. A few countries had built large research reactors for the production of isotopes and to study the behaviour of nuclear fuel, but the small training reactor had not been developed. Since then, research reactors have been constructed all over the world, and now more than 250 are in use. The 1961 Vienna International Reactor Conference was devoted to an overall review of problems of organization of research reactor centres, selection and training of staff, experience gained in operation and on the scientific use of research reactors. More than a hundred papers were presented and are published here in three volumes: the first on the organization of reactor centres of research, the second on experiences gained in the use of research reactors, and the third on more detailed statements about research programmes planned or being carried out in such reactors; but the classification is not very rigid, and there is much in Vol. 2 which concerns the subjects of Vol. 1. The present review deals only with Vols. 1 and 2. All reactor organizations should possess these volumes, for they contain a wealth of experience bought at great cost, and careful study might avoid waste and perhaps accident. Reactors can be dangerous: some accidents indeed have been serious and the utmost care is called for; constant vigilance and rehearsal of safety drills are essential as generations of students take over the controls. Hazard evaluation must be completed before a reactor reaches criticality and the right kind of operators must be chosen: as the Massachusetts Institute of Technology has found, "alertness is the primary requisite for a safe operation and by encouraging this quality problems are caught and rectified before serious consequence can develop".

The first requirement for a research reactor centre is to decide on the appropriate power output; 10–100 kW reactors can be permitted in built-up areas, those in the MW range must be in sparsely populated areas because of the danger from the iodine fission product if released from well-irradiated fuel elements. The papers from the U.S. Atomic Energy Commission, Associated Electrical Industries of Great Britain, the Technical Hochschule of Munich, the Atomic Energy Commission of Austria, and the Atomic Energy Commission of Australia deal with the health and safety aspects of the large research reactors, and it is clear that ensuring safety is an expensive item in the cost of a research centre. These reactors are capable of a large volume of research output; for example, as many as 100 simultaneous investigations are envisaged for the Munich reactor. For the training of students, the 10-kW reactor such as the *Triga* or *Argonaut* is ideal and very many of them are installed in universities with no special precautions about siting: their declared goal is the increase in national scientific manpower versed in nuclear science and engineering and, as Dr. Bradley of the U.S. Atomic Energy Commission pleads, these ought to come as additional tools to existing nuclear research and teaching and not be the main justification for the setting up of a national centre. Somewhere in between lie the group of reactors which can operate at 100-kW: rather large for training, rather small for extensive research into the damage created by fast neutrons. There are, however, many of these and more are planned like those for the universities in Great Britain, Queen Mary College, Imperial College of Science and Technology, and the Liverpool and Manchester colleges; the authors believe these will be mainly devoted to research, and many programmes are listed in the relevant papers.

From a long experience with the setting up of centres for training and research, Dr. Bradley pleads for a more careful assessment of the programme for which the reactor is required and then of the cost, staff and ancillary apparatus: many of the papers will help newcomers to make this assessment more comprehensive than they might have done; the great experiences of Oakridge and the Argonne Laboratories are given in detail. All the questions posed by General Atomics based on the sale of a score of reactors should be answered before deciding on a certain type of reactor.

There are good descriptions of the organization of the large reactor centres in Munich, Denmark, Australia and Canada, where 5- or 10-MW reactors are in operation, some on a basis of three shifts per day. It is a fairly common experience, specially mentioned in the paper from Lucas Heights, that initial assessment of the magnitude of the research programme which can be attempted with a given staff is over-optimistic, and the magnitude of maintenance is stressed by the Chalk River paper.

In Vol. 2 the experiences gained from some years of operation are listed in considerable detail. The Massachusetts Institute of Technology has high- and low-intensity beam tubes and has found that investigators prefer to wait their turn for the high flux from the 5-MW reactor rather than expose for long times at the lower intensity port. As the Massachusetts Institute and the Battelle Institute have tried to balance their budgets, they have given great thought to efficient operation and they emphasize the need for planning the experiment and testing the jigs most carefully before the reactor is ready to accept them. One penalty of arranging an enormous number of experiments to proceed simultaneously is the frequency with which the reactor 'scram' has been found to operate; greater care in design of safety circuits can alone cure this fault. There are many cost figures which appear to be very realistic, not extravagant, but not tinged with the familiar over-optimism associated with university ideas of costs. Another point of great value is the emphasis on space required: it has been found at Lucas Heights that congestion around the reactor is too great. To overcome this, the *Merlin* type reactor was designed to have a core capable of being raised to a second operating position; but experience with *Merlin* and with the modified *Merlin* called *Herald* weighs against this flexibility for sound technical reasons. The *Herald* paper draws valuable conclusions about the use of light water versus heavy water moderator for a pool reactor. Both these British reactors being pioneers of their kind contained features which would have been eliminated if more reactors of the same general pattern had been built. Emergency schemes for the higher powered reactors must be carefully planned and constantly rehearsed. A few papers deal with this, but only one boldly. In fact, in the discussion on operating experiences one author replied, "Normally, one does not bring the existence of emergency problems out into the light of day" (at least not in isolation, but only when mentioning advantages as well as risks !); other speakers and papers took the opposite line and referred to co-operation with police and Civil Defence. This seems to be the accepted policy, especially as pool-type reactors up to 5-MW do not need to operate in a pressure-proof building when built in the country.

This volume lists the many experiments performed with these powerful research reactors, including the medical therapeutic use of neutron beams in the Massachusetts Institute of Technology, the *Triga*-pulsed source at Brookhaven, and the thermoelectric generators at San Diego. These are necessarily brief accounts but they have the advantage of being listed all in one volume. They are too numerous to summarize or even to classify. It may be that from the numerous small reactors overseas little contribution to basic knowledge will come, but Dr. Hoffman, of General Atomics, rightly says, "Many of the human problems . . . arising in societies which are changing from an agricultural to a technological way of life are subject to an attack through an interdisciplinary approach; a handful of men working in this way with a research reactor may bring about a major human advance in those fields which directly affect the welfare of humans".

HAND-BOOK OF CHEMICAL ANALYSIS

Official, Standardised and Recommended Methods of Analysis

Compiled and edited by S. C. Jolly. Pp. xx+577. (Cambridge: W. Heffer and Sons, Ltd., 1963. Published for the Analytical Methods Committee of the Society for Analytical Chemistry, 1963.) 126*s*.

THIS book from the Analytical Methods Committee of the Society for Analytical Chemistry contains in its first section a collection of well-tried analytical procedures which are judged to be the most reliable and unequivocal methods available for each determination described, while the second part of the text is devoted to an extensive classified bibliography of selected literature references for the analysis of diverse technical materials.

The procedures adopted and formulated carefully in Part 1 bear behind them the weight of opinion and expert knowledge of the leading analytical chemists and analytical laboratories in the United Kingdom, and do not represent the chosen or preferred procedures of any one individual or laboratory. Not unnaturally, a very great part of this first section is concerned with the analysis of organic materials; but the text opens with an account of the determination of metallic impurities, principally arsenic, copper, lead and zinc, in organic materials. Chief attention is directed, however, to the methods used for destruction of the organic substance since this is the most obvious point of difficulty in dealing with such analyses. Next the text concerns itself with the determination of vitamins in various matrixes such as green-plants, cereals and meat, making extensive use of column and paper chromatography for separation and identification followed by spectrophotometry for determination. The analysis of essential oils is a less well-defined area, and warning is given at the outset that even slight variations in the adopted procedure are responsible for significant differences in results. Accordingly, very detailed instructions are given for these particular analyses, practically all of which are titrimetric in nature following initial saponification, etc. Methods are also outlined for the determination of the principal physical constants required with these determinations.

The analysis of milk products for solids, fats, sucrose, etc., appears to rest on a more satisfactory basis. Here, the analytical methods range from sedimentation and optical rotation measurements to chloramine *T* titrations. A thorium nitrate procedure is recommended for the determination of fluorine in foodstuffs following a steam distillation separation. Details are also given for the determination of fibre in 'national flour' and for water (oven-drying) ash, chloride, nitrogen, creatine, etc., in meat extracts, and for fatty acids in oils and fats. The methods requisite for the analysis of unsaponified fat, free alkali, etc., in domestic and silicated soaps are also outlined. A large section is next devoted to the analytical problems associated with trade effluents. These involve sampling, *p*H, suspended and dissolved solids, titratable acidity or alkalinity, hardness, organic matter, oxygen-level, etc. This is followed by more specific analyses for seventeen inorganic cations, and ten non-metals, including organic substances such as phenols, formaldehyde, synthetic detergents and organic nitrogen, and others such as cyanide, fluoride, etc. In these analyses the procedures adopted are largely those of micro- or trace analysis, and range from biochemical assay and spectrophotometry (principally) to flame photometry and classical titration.

This most valuable section of the book ends with the determination of a few selected pesticide residues such as DDT, benzene hexachloride, malathion and mercury (extraction, chromatographic clean-up, dechlorination or nitration, etc., followed by colorimetry), and a final chapter on the assay of crude drugs, for example, aconite, ephedra, gelsemium, jaborandi, rauwolfia, etc. These last-mentioned methods are mainly spectrophotometric or titrimetric following extractive separation.

Part 2 (pp. 235) provides a well-set-out tabular summary of the literature with regard to official, standardized and recommended or tentative methods of analysis for a very great range of materials as diffuse as antibiotics, paper and cellulose materials, cement, dairy products, disinfectants, explosives, fertilizers, solid fuels, hormones, ferrous metals, paints, rubber, soils, starches, wood, etc. This is undoubtedly a most valuable compilation. At a glance the reader can find the literature key to innumerable analyses with guidance ranging from the choice of an adequate sampling procedure, without which any analysis is largely meaningless, through to the opening-out treatment and a range of analytical 'finishes'.

At times one may feel that the Committee has been rather conservative in its selection of analytical methods, but this is probably inevitable where co-operative committee work is involved. There are, for example, instances where one feels that the use of radiotracer technique, activation or polarography could profitably have been used. The burden of analysis is by spectrophotometer and burette throughout, and it is, of course, appropriate since many of these analyses require to be done in reasonably equipped small independent laboratories, not backed by the huge resources of major industrial concerns.

Undoubtedly this is a serviceable and invaluable compilation which reflects credit on the individuals who undertook the tremendous amount of work involved, and on the Society for Analytical Chemistry, which devoted so much of its time and energy to the production of this handsome and well-produced volume.

GAS CHROMATOGRAPHY

Gas Chromatography

By Dr. Howard Purnell. Pp. vii+441. (New York and London: John Wiley and Sons, Inc., 1962.) 90*s*.

THE author of this new text on *Gas Chromatography* is already well known as a physical chemist and as an expert on the theory and practice of packed gas-liquid chromatographic columns. The book reflects these interests, but also gives a complete and up-to-date coverage of a technique which is still rapidly expanding.

It begins with a fairly full treatment of the essential physical chemistry relevant to gas-liquid and gas-solid chromatography, the thermodynamics of solution, adsorption, partition and vaporization and the kinetics of diffusion and of gas-flow. This section should be especially valuable to those who use gas chromatography but feel that their understanding could be broadened by greater knowledge or revision of the physico-chemical principles. The second section is an extensive account of the theory of gas chromatography and the manner in which parts of this have been or may be tested. The discussion is lively and great care is taken to relate the theory to practice. Points of present dispute are clearly brought out, and although, as in other parts of the book, the views of the author are emphasized, it is made quite clear where this is done.

The third and largest section is concerned with gas chromatographic practice; equipment and materials, detectors and analytical and non-analytical applications. Constructional details are given of all types of gas chromatographic and ancilliary apparatus. Stress is laid on katharometer (thermal-conductivity) detectors and on simple yet effective equipment such as may be constructed in the laboratory. Again the author draws extensively from his personal experience.

The description of the application of gas chromatography to various problems is deliberately curtailed,

although the main principles are well set out as is the influence which the various experimental parameters will have on the choice of method for a particular type of problem. Each chapter has its own bibliography and there is a helpful subject-index, but the treatment does not lend itself to an index of chemicals. A collected list of symbols would be an improvement in subsequent editions. The style is clear and vigorous, and the text is full of interesting speculations. All workers in gas chromatography will find it stimulating reading, and with its emphasis on principles it should be particularly suited to students.

C. S. G. PHILLIPS

REVIEWS OF PHARMACOLOGY

Annual Review of Pharmacology

Vol. 2. Edited by Windsor C. Cutting, in association with Robert H. Dreisbach and Henry W. Elliott. Pp. vi+477. (Palo Alto, Calif.: Annual Reviews, Inc., 1962.) 7 dollars.

THE second *Annual Review of Pharmacology* adheres to the form which has been so successful in the longer established series of *Annual Reviews* in biochemistry, in physiology and in medicine. There can be no question of the value of *Annual Reviews* to research workers and to teachers; however, there are those who would prefer a slightly different presentation. The lists of references given at the end of each review article are numbered, sometimes in alphabetical order sometimes in the order in which they appear in the text; standardization would ease the reader's task. In the text the references are given sometimes as the author's name followed by the number of the reference and sometimes by the number alone; if the reader wishes to know who was the author in the latter case, it is necessary to turn to the end of the article. The question of dates of publications is important, particularly when the reviewers refer to a number of related investigations. Although these are *Annual Reviews*, by no means every field is covered annually, in fact, the literature cited usually covers periods of 5–20 years: in one article the earliest publication cited is 1821 while in another it is 1959.

There is much to recommend to the publishers of *Annual Reviews* another commonly used system of citing references: to give in the text the names of the author(s) followed by the year of publication, and to arrange the list of references alphabetically. Since library facilities for most readers are far from perfect an additional convenience would follow if the titles of the papers were given, preferably in their original language, or if translated, with the original language indicated.

Of the articles in the present volume, Dr. Gaddum's history, "The Pharmacologists of Edinburgh" is the only one that can be read with enjoyment by the non-specialist. Chancey Leake's "Review of Reviews" is also of general interest. The reviews on the pharmacology of China, India and Central Europe are valuable in diverting attention outwards from the American–Western European pharmacological nexus. It is to be regretted that the international situation is such that Chinese pharmacology was not reviewed by a pharmacologist working in China. Dr. Chen's review was heavily weighted towards practical medicine, presumably reflecting the Chinese literature; perhaps this is as it should be in a rapidly emerging nation.

Each of the remaining thirteen review articles deals competently with various specialized aspects of pharmacology. Most of the contributors admit to some degree of selection in referring to the literature: clearly this is unavoidable if *Annual Reviews* is to be more than another abstracting service. On the other hand, a critical assessment of published literature has been attempted by only some of the contributors. If the objects of *Annual Reviews* are to collect together the most important recently published work in given fields, but to avoid presenting the opinion of the reviewers, they have been successfully achieved.

M. J. RAND

SCIENCE AND DEFENCE POLICY

The Rise of the Boffins

By Ronald W. Clark. Pp. xix+268+16 plates. (London: Phoenix House, Ltd., 1962.) 25*s*. net.

MR. CLARK, who was a war correspondent with the Canadians, gives us in this book a vivid account of the influence of science on defence policy, and more particularly of the relations between scientists themselves in that field and between scientists and the Services. It is far more than a competent piece of journalism; while he is concerned largely with personalities, they are not allowed to become obsessive, and the Tizard–Cherwell clash is handled with fairness and judgment in which the author's own leanings are obvious but not allowed to obscure the issues. It may not be a scholar's book, and it is written in a style which should deservedly commend a popular as well as scientific audience. Nevertheless, although Mr. Clark relies in this book very largely on unpublished material, including the archives of the Royal Society, and the help of many of those concerned with the events with which he deals, his book is better documentated than many more pretentious works. Apart possibly from Tizard's own Haldane Memorial Lecture and Messel Memorial Lecture, his brief bibliography omits scarcely a major reference although, admittedly, as regards the development of relations between scientists and the Services during the First World War, much material is scattered through autobiographies and biographies of the type of Sir Frederick Sykes's *From Many Angles*, on which it is a matter of opinion as to whether it should or should not be included.

As a piece of exposition, the book could not easily be bettered, and scientists themselves would do well to note this demonstration of the practicability of easy communication free from jargon; even the curse of abbreviations is held tightly and reasonably in check. It is also a useful contribution to the study of the interrelations between the scientist and public affairs, correcting, for example, a certain imbalance in Lord Hailsham's recent book, *Science and Politics*, and not the less effectively because Mr. Clark never assays specifically to discuss such general issues. From his brief initial account of interrelations during the First World War his chapters describe successively and fluently the development of relations during the inter-war years to the establishment of radar and the first crude attempts to mobilize Britain's scientific resources at the onset of war. Specific contributions of science, both defensive and offensive, are clearly described as the account continues into the war years, and technical details are not allowed either to daunt the general reader, or to cover weaknesses or failures in system or personality at various levels. It underlines much that is soundest in Sir Charles Snow's lectures on "Science and Government" and in Lord Hailsham's more recent book, illustrating, for example, the crucial importance of the three desiderata which the Minister for Science lays down for Britain's educational system. It is not for a book of this character to describe, much less prescribe, the means, or the mechanism of decision; there could, however, be no more effective demonstration of the imperative necessity for reason to be at the cutting edge, and the suggestion that reason indicates that the best solution to most defence problems often lies in not going to war at all in no way detracts from that demonstration.

It is a pity that the author uses the vulgar expression 'boffins'.

URGE AND MOLECULAR BIOLOGY*

By Dr. PETER T. MORA

National Institutes of Health, Bethesda 14, Maryland

LIVING entities, at all levels and in almost all their manifestations, have something of a directed, relentless, acquiring and selfish nature, a perseverance to maintain their own being and a continuous urge to dominate their surroundings, to take advantage of all possible circumstances, and to adjust to new conditions. The more 'vital' a living thing, the stronger this urge. Often this domineering, this taking advantage, this fighting is directed against other living entities; but the acquisition or absorption of metabolites, the urge of self-continuance goes on also in the absence of other living entities, for example, when a bacterial or mammalian cell is growing and multiplying in a nutrient medium.

Although life is relentless when it can express itself, it is not necessarily active all the time, but may alternate active with dormant periods when rest is more favourable or necessary. Periodic or cyclic activities are quite common in living processes.

Of course, all this urge and activity is temporal so far as any individual living entity is concerned. It declines with age and ceases with death, but its existence, while it lasts, makes living entities recognizable and distinct from non-living.

Biochemistry and molecular biology are unravelling nowadays more and more of the fascinating molecular details of living processes. We know, for example, that in reproduction complex macromolecules participate in a sequence of events: DNA, RNA, proteins, various enzymes using the energy supplied by certain phosphates (ATP) build up and down the recognized units of living material, the molecules of various sizes and complexity. We are beginning to know something about the sequences, the complex interrelations of such processes, and to recognize certain of the signalling and guiding elements, all as expressed by changes in molecules. It is natural for us to think in terms of molecules, since molecules are our tools of investigation and means of expression, or more exactly, symbols of our understanding of the physico-chemical processes of life.

The question raised here is: Are present molecular approaches sufficient to lead us to the understanding of the difference between the living and the non-living, or more explicitly, of what I call the 'biological urge' ?

I shall proceed first by defining this urge, and then by attempting to show it to be distinct from other biological phenomena now under successful investigation by molecular approaches, such as selection and evolution through random mutation, some form of adaptation, etc. I also shall mention briefly what other approaches, such as cybernetics, the principles of control and communication, feedback mechanisms in biochemistry, especially in microbial genetics, etc., may or may not offer toward the elucidation of the phenomenon of biological urge. Then an attempt will be made to show that the traditional approaches of physics or chemistry, be they thermodynamic or kinetic-statistic or, so far as I understand quantum mechanics, do not seem to be adequate. After that the modern scientific approach or method, as developed since the Renaissance, will be examined to see if it is capable of dealing with the problem of life. Finally, further personal and general opinions will be presented about what we should do in order to be more successful; but I am afraid I cannot be very definite, because I cannot see clearly the nature of the new method, or the extension of the physical methods, I feel it is desirable to find in biology.

* This article was prepared while I was assigned to the Virus Research Unit, Agricultural Research Council, Cambridge, England, and was read during a colloquium in the Department of Biochemistry, University of Oxford, on February 4.

Definition of Biological Urge and Delineation of the Problem

Living entities have several characteristics which make them distinct from non-living. They are autonomous; the individuals are similar but not exactly alike; they group in hierarchical systems; their mature state is more or less invariant, but still they are in continuous flux. They are self-maintaining; they build a complex and highly improbable structure necessary for the fulfilment of their function; they restore this structure when worn out, and repair it when damaged. They continuously adjust themselves to their environment, and they may adjust to even completely novel conditions, which they or their predecessors never could have faced before. Most important of all, a certain urge or drive towards self-fulfilment characterizes the living organism in all its activity and at all levels, from the simplest to the most complex.

Several words have been used for describing at least certain aspects of the last-mentioned attribute. Unfortunately, almost all the words available are anthropomorphic and therefore have some unwanted associated meaning; moreover, they often include properties which can be explained by evolutionary selection. Some of the words, such as 'wholeness'[1,2], 'directiveness'[3], 'orientedness'[4], are not very useful for my purpose, and others, such as 'purposiveness'[5], 'consciousness'[6], 'entelechy', or '*vis vitalis*', are clearly unsuitable, because they imply more than the materialistic approach I intend. I choose 'conatus', which, used in this context (Spinoza[4]), means drive, effort or urge. I hope the word urge is unpretentious enough (actually it is almost vulgar) to prevent my being labelled a metaphysician. At the same time it best indicates to me the most important and peculiar attribute of the living, the relentless striving to survive, to absorb, to expand, to dominate.

The assimilation of metabolites, the continuous use of energy for the sake of the living entity, is an example of the urge. A living entity (for example, a cell in tissue culture) does try to expand, organize the elements around it (the random mixture of molecules in the medium) and, so to speak, subjugate or dominate its vicinity, regardless of whether it encounters other living units or not. Now consider the formation of a clone from a single cell. Replication, and generally reproduction and progeny formation, may be thought of as an extension or even a consequence of the urge of the individual living unit towards self-continuance and a spreading over or overwhelming of the available suitable space. So far as I know, no good reason has been advanced on a molecular level for the occurrence and perpetuation of both these processes. The fact that we now are learning about the key molecules (intermediary metabolites, DNA, enzymes, ATP, etc.), their structure, and some of the details of the mechanism of metabolism and of replication on molecular level (the complicated schemes of intermediary metabolism, DNA strand separation, complementariness of nucleotide bases and the pertinence of this to replication, etc.) does not explain why metabolism and multiplication

occur at all, or why living systems build their improbable but functional structure, or what keeps them living.

The problem I raise of how to approach such obvious phenomena by scientific research is not helped by saying that this is just in the nature of living matter, an inherent attribute[7], the way mass or gravitational attraction, etc., is an attribute of matter[8]. But mass, gravitational attraction, and other physical properties are inseparable attributes of all physical matter, and they are not restricted by time to a certain period. The urge is a peculiar attribute, restricted only to the matter of the living while the living is alive. Fundamentally, I am indeed asking what the difference is between the living and the non-living matter, and whether molecular science as we know it is capable of dealing with this question.

This question then asks why is living matter alive, and actually involves really not the 'how' but the 'why'. One may say that the purpose of science is not to answer the 'why' but the 'how', and the question of 'why' should be left to philosophy or to belief. However, I do not question why living matter exists at all, as this would be a part of a philosophical problem of existence in general; but how to approach scientifically the problem of to what extent and why living matter is different while alive from the non-living matter.

We know, of course, that living matter consists of nothing but molecules. But are not these molecules only agents, means of practical expression of the urge, simply units of the complex interrelated functions in living processes ? In contemporary biochemistry, as Paul Weiss said[9]: "there seems to be a predilection for identifying agents and charging them for responsibility of action". I will make a qualified exception to this, when later discussing viral DNA.

It would be pertinent to my question to consider the functional interrelationships of molecules, their mutual influence, the information transfer between the molecules. Cybernetics and other related approaches claim to give such methods to biology. Indeed, theoretical considerations, such as in cybernetics, or experimentally found details of feedback, such as in metabolic cycles, or in the function of genes controlling some enzymes in micro-organisms[10–13], represent important advances in our understanding of the control of living processes and show how information can be co-ordinated on a molecular level for the benefit of the living entity. For example, the expression of a series of structural genes appears to be controlled by the cytoplasmic product of a regulator gene, called the repressor. The repressor can be either inactivated (induction) or activated (repression) in a medium deficient in metabolites, allowing the bacterium to adjust its enzymatic mechanism to the medium[11]. But this does not answer the question of why such processes occur, and what drives the processes. In other words, I cannot see how cybernetics and details of feedback processes, etc., can give the reason for the continuous drive, the urge of the living entity for self-continuance and reproduction. Furthermore, cybernetics does not claim to say anything about the origin of such processes. Still, cybernetics and the recognition of details of information transfer, of feedback, etc., in dynamic biochemical processes seems the most suitable of the available methods to examine the problem I pose: in living processes, even in the simplest living unit, such as a cell, millions of molecules participate, and their interrelation, their mutual influence or control, their co-functioning is essential in space and time.

Let us consider a process, the virus cell interaction, which is in a borderline area. Viruses, of course, in themselves, do not manifest any urge or any special attribute of the living. They are merely stable macromolecular complexes consisting of nucleic acid surrounded by protein. However, when they are brought by random mechanical forces, such as by Brownian motion in a liquid medium, to the vicinity of a host cell, a whole sequence of complicated molecular processes start in a very directed manner, and the sole objective appears to be to produce a large number of viral progenies. In their resting phase, without the host, viruses might be considered analogues of the living entities in their dormant phase; however, viruses have absolutely no metabolism without the host. Their life-cycle, and the factors influencing or favouring the different cyclic phases (temperature, deuterium oxide) are under investigation[14]. When viruses collide with a host cell, and the conditions are right for the manifestation of their potential, then a whole sequence of amazing, interrelated events begin. For example, the tail sheet protein of the *T*2 phage contracts, probably triggered by fresh SH groups freed after oxidation of thiolester bonds by a metal ion present in the receptor *E. coli* cell-wall. This leads to the penetration of the bacterial cell-wall by the tail core. Then a single[15] molecule of DNA is injected, together with a small amount of internal protein[16–18] and certain amines[19]. Then the cellular processes in the bacterium completely change[20,21]. The synthesis of bacterial DNA and RNA almost immediately stops, there is a breakdown of the bacterial chromosomes by an activated DNase, and a new kind of intermediate hybrid DNA–RNA complex is produced[22]. This is followed by further very complicated and little understood changes in the metabolic processes of the *E. coli* leading to the formation of a considerable amount of fresh phage DNA in the double helix structure, which is eventually packaged in a particular folded form together with the internal protein and the amines, and then this is surrounded by newly formed phage head protein and the complex tail is attached[20]. About 200 identical progenies are produced within 20 min. The progenies are then released automatically, as the bacterial cell is lysed by a freshly synthesized lysozyme.

Similar reproductive processes can be initiated by the nucleic acid of a virus, when conditions are such that bare nucleic acid without the presence of the virus protein will penetrate into the cell; for example, when facilitated by changes in salt concentration. Infection[23] of *E. coli* protoplast by a single stranded ring form[24] of ΦX 174 DNA, or by λ DNA (ref. 25), or of cells of a mouse embryo in tissue culture by the DNA of polyoma virus[26] are such examples. Thus, DNA alone, and apparently only one molecule of DNA, either in double helix or in a single stranded form, has inherently all the information necessary to initiate progeny formation. Truly, it appears, this molecule is a full cause of initiation; but it is not responsible alone for all the processes which happen inside the bacterial cell. Host enzymes, the whole metabolic and energy-yielding apparatus of the host cell and the interrelationships inherent in the host bacterial, plant, or mammalian cell are necessary for the production of viral progenies. The viral nucleic acid represents only a 'misinformation', which starts the host cell on a new and often disastrous path[27] ending in cell disruption, or in lysogeny, which is a form of a symbiosis, or in neoplastic transformation[28], which is probably associated with sufficient alteration in the antigenic make-up of the cell[29] to allow it to escape contact inhibition by other cells[30]. Thus, the initiating cause and full information for the particular direction of metabolic activities of the cell are supplied by the DNA.

Recently, systems simpler than a cell were found to exhibit certain aspects of building up of organized structures which resemble or copy the biologic macromolecules. I am referring, for example, to the polynucleotide synthesizing enzyme system of Kornberg *et al.*[31], and to the ribosome extracts containing *s*RNA and fortified with ATP and all essential amino-acids which were found by Nirenberg[32] to support the polymerization of amino-acids as directed by added polynucleotides. Both systems use biologically preformed macromolecules and specific structures (the DNA polymerase[31] or various other enzymes together with soluble RNA and the ribosomes of *E. coli*[32]) which then intereact so that a polymer, a polynucleotide

or a polyamino-acid is synthesized from the existing pool of the monomers. The synthesized polymers resemble in structure the natural polymers or follow the information supplied by the added template. The Kornberg system can produce homopolymers (a simple polynucleotide) or regularly repeating copolymers (cf. *d*AT copolymer[33]) in the absence of a primer polynucleotide, or can produce a polynucleotide or a DNA with the expected sequence and of biological function (cf. transforming activity[64]), determined by the primer. In the Nirenberg system the *E. coli* extract on addition of synthetic polynucleotide (synthetic 'messenger' RNA) can produce polymers of amino-acids with the frequency of the amino-acids (and presumably also the sequence) determined by the information contained in the base frequency (sequence) of the synthetic messenger. In fact, on addition of virus RNA a certain amount of virus-like protein can be produced. For example, on addition of tobacco mosaic virus (TMV) RNA the newly synthesized protein weakly cross-reacts in serological tests with the TMV protein, and also recombines to an extent (about 10 per cent) with TMV RNA[35]. However, these synthetic processes are limited in two respects: (1) they come to an early halt; (2) they represent only isolated small portions of the synthetic processes which occur in living cells. Although they produce a certain amount of absence of randomness, because of the preformed specific directing biological macromolecules (enzymes, templates) and other, still intact, more complex cell components (ribosomes), basically these are polymerization processes which produce polymers and copolymers, some with a specific sequence, using ATP as the energy source, and the initiation and the orientation of which are controlled by the intact biological polymers present.

The purely chemical polymerization or polycondensation processes which give polymers resembling biological macromolecules are more primitive models. Some are random processes, such as the heating of ammonium cyanide in aqueous solution[36], heating of amino-acids[37], sugars[38] or ribonucleotides[39]. Others are polymerization processes in which certain chemical bonds are favoured: Khorana's method of polymerizing thymidylic acid[40], certain forms of amino-acid anhydride polymerization which produce polyamino-acids[41]. In all these cases, however, the restrictions with regards to the particular bonds to be broken or formed, and thus the structure of the resulting polymers, are inherent in the bond energies and structures of the monomers and in the treatment applied (heat, catalyst, initiator, etc.). These polymerizations are only exercises in synthetic organic chemistry. They use similar monomers, but they do not really resemble a self-perpetuating, co-ordinated process, and they do not lead to the synthesis of a living unit with the characteristic urge. They do not even produce functional polymers with specific structure.

But could not similar polymerization processes add up to this, and life be synthesized one day ? Is it not claimed by some, and indeed believed by the majority of scientists that life originated from a suitable mixture of molecules in the distant past in some similar way ?

These are two questions to be argued according to one's disposition; but I do not believe they can be answered at the present time.

The first question will be taken out of the realm of opinion if and when the first living unit with the characteristic urge toward self-maintenance, assimilation and reproduction is synthesized. Until then, it is a matter of one's preference or belief whether this can be achieved or not. Obviously, all the necessary molecules when added together do not function, as in a cell homogenate, where we have destroyed the specific interrelationships and controls. Biochemists will agree that we are very far from knowing how this interrelationship and control comes about in space and time, and we do not, at least not yet, foresee the synthesis of a functioning, living unit from a molecular level. Claim to the contrary comes from insufficient biochemical knowledge or from a belief that the present molecular biology will supply the information imminently. The last tenet is exactly what I am questioning. Characteristically, such claims come more frequently from physicists or chemists who examine biological macromolecules, than from biochemists, and scarcely ever from those biologists who work with a small living unit, such as a cell.

As to the second question, how life originated, I am afraid that, since Pasteur, this question is not within the scientific domain, at least if we consider provability as an essential part of a scientific statement. Some light might be thrown on this problem, however, if we find a certain form of life outside the Earth, and if we analyse that form of life. Scientists nowadays are inclined to expect this, probably because of their pre-occupation with statistical or chance processes and their preference for accounting for facts by existing knowledge, and also from their disinclination to consider the Earth as a singular part of space. They expect that in other parts of space where favourable conditions similar to the Earth's have existed, that is where there was available for a long time a high concentration of complex molecules from polyvalent atoms[61], a self-maintaining, matter-acquiring, energy-producing, reproducing, living unit also appeared.

Even if we find this (and in my opinion we have a better chance to find an answer to this on Venus or Mars, before we synthesize a living unit), we still will not know why this continuous urge exists to maintain and extend life against disrupting, randomizing physical forces, without careful examination of the new type of life. In fact, we might have doubled the problem I pose. However, the statistical, or chance theory for the origin of life certainly would receive very strong support, provided, of course, that a common origin of life (by meteors or by other 'infection' of planets) can be excluded.

In his book on the origin of life, Oparin[5] elaborates on the concept of selection on molecular level as the key process which tips the balance over from the complex aggregates of molecules which continuously build up toward a certain level in the direction of a functioning biologic unit, but break down because of the random physicochemical forces before they cross a theoretical borderline and form the first self-maintaining, absorbing, reproducing, etc., living unit. 'Selection', as Oparin and other biochemists use it in this context, includes a tacit assumption of acquisition, of positive action, of building up the improbable, more complex from the more probable, less complex, and actually increasing stability as complexity increases.

It is more than a passive and statistical phenomenon, common in chemical processes, where molecules are selected or rejected, for example, according to whether they fit or not when they happen to collide. Otherwise, the result would not be a self-maintaining, absorbing, reproducing unit, which will always tend toward more and more complexity as it evolves, but could be only a metastable temporary complex which will tend to disperse more and more as its complexity increases. That the word 'selection' in this context means something different from what it means in a chemical process is not often recognized. One reason might be that each biochemical process, when considered *in vitro*—for example, an enzyme-substrate or antigen-antibody interaction—is controlled by selection, in the passive, traditional physicochemical sense. However, such isolated processes will cease eventually; the molecules will disperse and degrade. There is no justification for expecting selection, on the basis of physicochemical principles, to operate in the positive sense, and there is no justification for involving it to account for the origin and continuance of living processes.

To me it appears that this is an extension of Darwin's use of the word selection in a third sense, which explains evolution of the living, but the Darwinian 'selection' and evolution concept was arrived at empirically, by observing

the reproduction and the balance of dominance of progenies of already-living units, and the spectrum of the living species.

We believe that Darwinian selection and evolution of living entities occurs because of random mutation. Mutation occurs as consequence of a chance phenomenon, and it is explainable statistically on the molecular level: for example, one or more nucleotide base in the DNA of a chromosome may be altered because of radiation, a mistake or other chance effect. The ingenious present work on microbial genetics is indeed very suggestive that selection and evolution occurs because of statistical phenomena on the molecular level.

Then, it appears to many molecular biologists, there is no need to invoke anything further. Living units are those which are selected because they are capable of survival and reproduction under the given conditions and any of their particular functions evolved exactly because of this selection. Any specific property of a living unit such as a certain metabolic activity of a bacterial cell is considered to be a direct consequence of the principles of selection and evolution; unspecific broad statements, such as about urge, etc., are meaningless when considered in this light. There was a high concentration of suitable molecules available and for a very long time before the first living unit appeared; a unique occurrence, probably, as suggested by the similarities in fundamental biochemical processes (ATP as a common energy source, etc.). Then, the aforementioned molecular-statistical-genetic processes led through selection to the evolution of the different forms of life.

The foregoing hypothesis is probably the best that can be proposed at this time, but when one thinks about it, shortcomings are evident. First of all, selection and evolution in the Darwinian sense occur only in the living and because of being alive. To invoke statistical concepts, probability and complexity to account for the origin and the continuance of life is not felicitous or sufficient. As the complexity of a molecular aggregate increases, and indeed very complex arrangements and interrelationships of molecules are necessary for the simplest living unit, the probability of its existence under the disruptive and random influence of physico-chemical forces decreases; the probability that it will continue to function in a certain way, for example, to absorb and to repair, will be even lower; and the probability that it will reproduce, still lower. Statistical considerations, probability, complexity, etc., followed to their logical implications suggest that the origin and continuance of life is not controlled by such principles. An admission of this is the use of a period of practically infinite time to obtain the derived result. Using such logic, however, we can prove anything, including that, after a suitably long time, everything will repeat itself exactly, and I will write again these same lines under exactly the same conditions. When, in statistical processes, the probability is so low that for practical purposes infinite time must elapse for the occurrence of an event, the statistical explanation is not helpful.

There is another escape clause in the statistical hypothesis of origin and continuance of life as coupled with the statistical selection and evolution theory. The simplest, earliest and most labile forms of life, it is explained, are extinct, and this is why we are unable to see exactly how life originated. One may argue that alternative hypothesis that one or a few similar, self-reproducing, living units were brought or appeared on Earth in some relatively advanced stage of evolution. If life appears because of statistical causes, it should continue to appear no matter how rarely, unless conditions have drastically changed, and we should have a chance, no matter how small, of finding surviving units in all stages of development, including the earliest ones. Also, as already mentioned, the similarity of fundamental biochemical processes suggest that life appeared only once; in a statistical theory it is very difficult to explain why it did not happen at least twice, or if it happened more than once, why it happened exactly the same way.

Of course, the alternative hypotheses still do not say how life originated or why it continues. I would like to show that speculations on the origin and continuance of life are in such a vague state that they are not amenable to proof. There is a semantic confusion in the indiscriminate use of the word 'selection' which has at least three different operational uses in these contexts and this then leads to an illusion that it operates in another sense in another field. Our speculations are generally dominated by our present statistical orientation, which is prevalent and successful in physical sciences and in certain aspects of genetics. To invoke statistical and probability concepts to explain the origin and continuance of life does not appeal to me when I consider that the expression and the consequence of life, from which we detect the presence of a living unit, is exactly opposite to what we would expect on the basis of purely statistical and probability considerations. (I refer to the creation of order on a very complex level.) I do not have a scientifically more satisfying theory to suggest in its place, and I beg only ignorance.

However, Darwinian selection and evolution of already living entities is probably under statistical control; it is a consequence of mutability, and so are apparently some aspects of cellular regulatory mechanism[13,65].

In certain cases it is recognized that changes in the cellular regulatory mechanism are the direct consequence of mutation, such as when bacteria mutate so that constitutivity becomes dominant, and the operator becomes insensitive to the repressor. An example of this mutation is when the mutant bacteria will synthesize β-galactosidase and permease in the presence of the repressor. Generally, it was found that the cellular regulatory mechanism reaches back to the gene-level. For example, it is assumed that in the case of β-galactosidase and permease synthesis a regulating gene produces an apo-repressor, and a repressor is synthesized from this only in the presence of a co-repressor, which may be a product of metabolism of the energy source, for example, glucose; while lactose, which is the inducer, competes with the co-repressor and prevents the formation of the repressor. When no repressor is present, the operator gene instructs the structural genes to synthesize the enzymes of β-galactosidase and the permease. However, cellular regulatory mechanism, to some extent, may operate below gene-level. For example, part of the regulation of histidine biosynthesis proceeds through the specific inhibitory activity of the end product, histidine, on the first enzyme of the biosynthetic pathway, and the enzymes in the later stages of the pathway are deprived of their substrates[66]. This is negative feedback mechanism, and the control is corrective.

Another type of regulatory mechanism may depend on the states of aggregation of a certain enzyme protein, for example, glutamic dehydrogenase in the disaggregated state will lose its specific activity, but will acquire a new enzymatic activity, that is of L-alanine dehydrogenase[66]. The ability of a cell to synthesize or not to synthesize this or that enzyme, or to adjust by this or that mechanism to a change in the environment, whatever is the mechanism, is generally looked on by molecular biologists as a consequence of mutability, thus purely of chance. However, chance, while it operates to select the varieties of the mechanism of the existing living organism, is not a sufficient cause.

One may consider evolutionary selection as a passive aspect of the activity of organisms, which are already living and which are capable of reproducing, in the sense that they are under the control, or more properly at the mercy, of the external physical conditions which might lead by chance mutations to progenies more suitable for the changing conditions. To allow selections by mutations, there must be present an ability of the organism to reproduce persistently.

The difficulty in accounting by probability for the occurrence of the first reproducing unit was mentioned earlier. Now we need to account for a persistent ability to reproduce, so that beneficial mutation can occur to select the organism which is more suitable for survival. We know that the frequency of mutation of simple present-day organisms is rather low, and, in any event, mutations may well be deleterious or lethal; as a matter of fact mutability was used to account in a hypothesis for ageing and death of multi-cellular organisms[37]. Mutability should be considered as a consequence, and not the cause, of the persistent ability to reproduce.

A certain amount of selection of macromolecules occur in biology, but again only when living units operate. Anfinsen[42] has presented a plausible story of why we find differences in structures of important proteins, such as in the sequence of insulins in different species, and how complicated enzymes, such as RNase or lysozyme, may have evolved from simpler molecules. This type of evolutionary process might be based on the selection of a macromolecule according to whether it had the best structure for enzyme activity under the given circumstances. But again selection, although macromolecules are selected, occurs within the living unit. Thus selection on a molecular level should not be used as a reason why living units appeared, or explain why a living unit maintains and expands itself in spite of the random disrupting physical forces, or why it reproduces.

It is thought that compartmentalization through membranes, higher concentration of enzymes, different kinetics of enzyme reactions in gel[43], etc., occur in living cells so as to increase efficient enzyme concentration, etc. and thus favour certain processes. Reorientation of linear macromolecules in membranes was proposed as a unifying principle, underlying cellular selectivity[44]. These are, of course, useful concepts, and the latter theory especially might be useful in explaining the details of initiation of many biological phenomena by selective molecular interaction. It is a peculiarity of the living systems, however, that the local concentrations, permeability, etc., are produced and changed continually as benefits the cell. This is not molecular control of cellular activities, but "cellular control of molecular activities"[9]. Even if there was once a favourable selective concentration of molecules, in the primæval coacervate of Oparin, producing the first reproducible unit, why should continuous reproduction occur to allow development of organisms through selection so that they have an ability to control rate processes to take place exactly so as to benefit the living unit at that moment? This is another way of putting the problem, which to me cannot be answered by invoking selection on a molecular level. Keep in mind that Darwin's selection principle is a necessary but not sufficient condition for explanation of development of different forms of living processes.

I am aware that the properties of the building blocks of matter may inherently contain the information necessary to automatic formation of the resulting unit of higher hierarchy with a specific or single structure. For example, amino-acids under certain conditions will polymerize to form an α-helix[45], poly I and poly C will form a DNA-like double helix[46,47], a reduced RNase with sulphydryl groups in the random coil will reassemble into the original tertiary structure with S–S links and recover the full activity of the enzyme when gently oxidized[48], collagen will aggregate[49] *in vitro* with a characteristic spacing of 640 Å, TMV protein and RNA recombines to a normal virus structure with 16 1/3 sub-units of proteins per turn in a helical arrangement with an RNA coil joining them up in their groove[50], etc. These are, however, limited processes, similar to crystallization; an end is always in sight and the organization stops at the next hierarchical level. Most important of all, there is no resulting continuous function, continuous rearrangement or change, or any expression of the urge.

Organization of cells also may occur *in vitro*, apparently controlled by their physico-chemical (surface, etc.) properties. For example, a single cell suspension of a tissue may reassemble in culture to show certain of the characteristic features of the tissue from which the cells came. Again, the information was biologically pre-formed and the reorganization occurs only to a certain level (next hierarchy) and there is no continued function without the control of the whole (in this case the organism). Obviously, this is not the full story in processes such as wound healing, or differentiation, or dedifferentiation. I do not intend to go into these problems, since I do not know enough about them. I simply propose that there are problems in biology on all levels where some kind of urge is evident characteristic of the living; but in detail, so far as we know, it always operates through the well-known physical forces and elements of matter.

Thus, the paradox: well-known molecular forces, exactly the same which operate in the physical realm, appear to operate inside the living units when considering any particular detail, but they are under the control of the total living unit, and in final analysis this is a consequence of an unexpected perseverance of the living unit to maintain of its own being, of an urge of self-continuance, expansion, and reproduction. Living processes persist to a degree improbable in a physical system.

Scientific Approaches

One may approach this problem by several methods useful in dealing with the physical world. One is thermodynamic.

The second law of classical thermodynamics postulates an overall increase of entropy. Of course, certain local areas where the entropy is decreasing are common, such as in crystallization. In crystallization, the full process is determined by the valency, the molecular structure of the components, whether atoms, molecules or polymers. Crystallization occurs because it leads to the lowest energy state, and to the most stable arrangement of atoms or molecules under the given conditions. Crystallization leads to simple, very uniform repeating structures, which are inert. These structures do not function, and are not designed by function. (An exception to this is the case when biologically pre-formed molecules re-combine, such as the aforementioned example of reconstitution of a functioning virus from its protein and nucleic acid component.) In contrast, living structures are organized under the control of other living units, when the molecular conditions alone would not favour their formation; their structure is far from simple or stable. They are designed to function, and indeed they do function; they continuously absorb, expand, reproduce.

Living organisms continuously draw negative entropy from their environment and do this so consistently that this was considered to be their main difference from the non-living[51]. When they die, they lose this ability, and simple molecular forces take over, leading normally to dispersion, but also sometimes to crystallization of certain components. It is possible to crystallize out amino-acids from a cell homogenate, but not from a living cell; actually prevention of crystallization of water and other molecules is necessary to maintain the viability of small organisms or of tissues, when cooled to very low temperatures.

It is fitting to apply the thermodynamics of irreversible processes[52] to biological systems[62]. This thermodynamics considers 'open systems', which continuously exchange both energy and matter with the exterior. In such systems, in the 'stationary state', as Prigogine showed[53], internal irreversible processes always operate in such a way that their effect is to lower the value of the entropy production per unit time. When a system is in a state of minimum entropy production, it cannot leave this state by a spontaneous irreversible change. If some fluctuation

cause deviation, internal changes will take place and bring back the system to its initial state. This would correspond to the tendency of the living organisms, in their fully grown state, to maintain their structure against external perturbation, and it also means that there should be a tendency toward minimum metabolism in this state. The entropy of the matter entering the system has to be smaller than the entropy of the matter given off by the system to the external world. The system 'degrades' the matter it receives, and the stationary state is maintained by this degradation. All the foregoing pertains to the stationary state. Now consider the evolutionary state towards a stationary state, which corresponds to growth. While it was shown by Prigonine that often the entropy of such a system itself may decrease, in other cases, however, it may increase. Actually the latter would always be the case for isolated systems if it were not for the fact that such systems cannot be in stationary non-equilibrium state.

While from the point of view of the thermodynamics of the open and stationary systems the behaviour of organisms is not contradictory with regard to the change in entropy, the problem is far from being fully resolved. There remain the questions why living processes operate as irreversible processes so that the entropy content decreases invariably in the system in the growing state, and why do they immediately revert to increase of entropy on death ? There has been regrettably little research on these important problems, and I have seen no present experimental work pertaining to biological systems.

So far as some aspects of the kinetic approaches are concerned, I expressed myself in a recent article, on "Directiveness on Molecular Level ?"[53]. The gist of the article was a query: whether by the methods of molecular kinetics we can describe the phenomenon of directiveness, or more exactly, prove the full efficiency of an interaction, evident when observing an individual living entity. The term directiveness may encompass much more than directed interactions, and may be used to include phenomena I group under the term 'urge', as E. S. Russell did in a brilliant book[3] in which he surveyed directiveness in the field of animal physiology and behaviour. I must say, however, that many of the phenomena Russell described could very well be described by evolutionary selection.

In my article I considered only the problem of interaction. My approach was to go down the scale from obvious examples in our visible world (an animal goes toward its food or shelter, etc.) to molecular dimensions. The attachment of a bacteriophage on to its bacterial host is a process in which every collision appears to be successful, or, more properly, where infection of the bacterium with DNA occurs every time a bacteriophage happens to collide with the bacterium, and results eventually in progeny formation. This occurs in spite of the fact that only a small percentage of the bacterial cell-wall surface is suitable for penetration and injection of the DNA by a particular phage. Of course, purely physico-chemical factors are responsible for this process when the details are considered: the tail fibres might be complementary to certain areas on the bacterial cell-wall, the rotational diffusion of the head-heavy *T*2 bacteriophage must be greater than the translational diffusion, so that the tail tip or the fibres on the tail tip should have a much better chance of touching the cell surface than, for example, the head protein. Then irreversible attachment follows only when the complementary molecular structures meet. The neutralization of the tail tip of the bacteriophage with its antibody also seems on first sight to be a process where the collisions are fully effective.

In studying interaction on a molecular level, observation is necessarily restricted to the sum total of the effect of a very large number of molecules (as in an enzyme assay, for example), and it becomes clearly impossible to conclude that the process has full efficiency. We can qualitatively demonstrate that, to a certain extent, directed or oriented interactions may occur between molecules: an enzyme such as RNase may attract its substrate, RNA, *in vitro*, so that collisions may be more efficient than they would be when the collisions occurred at random without the attraction caused, for example, by suitably distributed opposite charges on the two molecules[54].

Unfortunately, in neither of the foregoing cases is it possible to prove collision efficiency even within a few orders of magnitude because of inherent theoretical and experimental limitations[63]. Thus, on or near the molecular level, the kinetic approach does not appear to be suitable for dealing with efficiency of collision, while full efficiency of interaction may be obvious on a larger scale, when the fate of each biological entity can be followed unambiguously.

Calculations by classical quantum mechanical methods by Wigner[6] resulted in zero probability of self-reproducing states provided, of course, that those approaches and assumptions which Wigner made are accepted. Wigner noted that his crucial assumption, that is: "a Hamiltonian which governs the behaviour of complicated systems is a random symmetric matrix", is analogous to another assumption, that is "in no system of any complexity is there accidential degeneracy", which was used by von Neumann to arrive at the second law of thermodynamics by quantum mechanical methods. I am impressed that an eminent quantum physicist, like Wigner, concluded that the classical methods of quantum mechanics are not valid so far as living systems are concerned. Thus, Wigner concludes that either quantum mechanics as it stands has to abandon its claim that it comprises a valid explanation of all that exists (and let us remember that the aim of the biochemistry or molecular biology through chemistry and physics is to put understanding of living processes eventually on quantum mechanic basis), or quantum mechanics has to consider aspects not thought of previously, or not necessary when dealing with the purely physical world[6] (see also ref. 34).

Such new aspects, according to Wigner, should include consideration of 'consciousness', which apparently "controls much of the living process, and thus in reverse. living process might be also controlled by it. . . . The description of this phenomenon (consciousness) clearly needs incorporation into our laws of nature of concepts, which are foreign to the present laws of physics". He suggests, that the situation might be analogous to the understanding in the past century of the relationships between light and matter. We had known that matter influences light, but we were so immersed in the investigation of macroscopic phenomena that until the discovery of the Compton effect we had not suspected that light also influences matter. Obviously, Wigner uses the word consciousness differently from its usual anthropomorphic meaning.

Another way out of the deadlock could be the recognition of some kind of law specific to biological systems, a 'biotonic' law, so-called by its proponent, Elsasser[55].

Thus the problem is recognized: the methods of (atomic) science are not sufficient, and they lead to contradiction when we try to explain the peculiar essence of living systems, and when we consider a living system as a whole. Why is this and how did we get into this position ?

The Methods of Science

In a recent book[56] Waddington contrasts the atomistic approach versus a continuum approach in biology, using as an analogy the dualistic approach of dealing with certain manifestations of the elementary particles in modern physics. I believe, however, that there is a different and deeper schism here, one which does not offer an alternative approach, but if we consider the evolution of scientific methods in modern ages, virtually excludes any but simplifying type of approach, which then leads

into a cul-de-sac so far as the description of the total living system is concerned. May I outline here my understanding of this development ?

In the Middle Ages, man's mind was oriented, and to a certain extent restricted, to consider eventual purpose as the principal aspect of each action or phenomenon, or even of any material entity. Scientific investigation and thinking was subjugated to consideration of purpose, and the minds of many eminent natural philosophers struggled with the complexity which is inherent in such a teleological approach: each phenomenon was but a small part of a very complex world, striving towards its final purpose, and had to be considered as such. Any negation of this attitude and seeking of a new approach was difficult and unwelcome.

No wonder that natural philosophy, or physics, was so unsuccessful for centuries during this teleological orientation; everything was so complicated, so much part of its surrounding and of the past, it was so difficult to see clearly the purpose, and there was so much written and thought already that one had to be aware of.

There was no real progress, until slowly, first tentatively and only in part, but later in its full force, the new scientific method emerged: Let us not consider purpose, especially not why things exist. Let us use, as our criterion of validity, the experiment or the observation, fully available to all. Thus the empirical approach, the principle of verification evolved. Let us examine only a limited aspect at one time: let us exclude disturbing influences (cf. Torricelli's experiment of the falling bodies in vacuum) and best, let us examine how only one variable affects a process (the angle of the incline and the roll of the ball; cf. J. S. Mill's *Canons of Inquiry*[57]). This is, in essence, the second and third of the basic principles of method of Descartes[58] which state, that one must divide each of the difficulties under examination into as many parts as possible, and then proceed always from the simplest and easiest to the more complex.

By this three-pronged approach, of: (1) avoiding teleology; (2) verification by observation; (3) simplification, a highly successful natural science was built up in the past three or four centuries. The physical world responded marvellously to our enquiring efforts.

By these methods we have achieved some success also in biology, drugs, antibiotics, the understanding of molecular details of this or that biochemical processes. We may ask, Is it then worth while to abandon this path; would not everything solve itself when all the details are known, and would not the pattern show itself ? Clearly this is the attitude of most scientists nowadays.

I do not advocate abandoning this successful molecular method in the investigation of any particular detail of a biological process. Molecules and the physico-chemical forces between them are the only agents and the only forces, so far as we know, which participate in the living processes. I suggest only that for the understanding of the behaviour of the total biological unit, for the examination of the essence of living, the present scientific method used in physics might not be sufficient. In the simplest living cell the complex interplay between thousands of molecules makes the living cell different from the non-living. A certain kind of exchange of matter and energy within and between the living units and with their media makes the process recognizably biological, and its past history, and the information transfers which exist within the living unit and with their suroundings make it possible to continue to function. This is well recognized, and investigations of enzyme induction, of intermediary metabolism, of cellular regulatory mechanisms[59], etc., pay attention to exactly these aspects, and modern biochemistry is not confined by the principles of Descartes. Indeed, modern biochemistry might lead to a new method of science. Still, the simplifying and analytical approach is generally dominant, and we physical scientists are often afraid, or unable, to deal with too much complexity.

In one respect, in the consideration of purpose, we seem to have a complete mental block. One who brings teleology into science might expose himself to a little ridicule, if not to a gentle inquisitorial castigation by editors of scientific journals or to the expression of exasperation by fellow scientists. But are we not avoiding this consideration of purpose because of the bad memories teleology evokes ? Properly, we try to avoid metaphysics, and teleology has no place in physical sciences. But the 'purposiveness' of living beings (and I quote from Oparin's book[5]) "pervades the whole living world from the top to the bottom, right down to the most elementary forms of life" and it "is an objective and self-evident fact which cannot be ignored by any thoughtful student of nature". I do not propose that in science we think about the purpose or reason for existence. I only wish that we could think freely, and design theories, experiments, and do research keeping in mind a limited[60] and very materialistic purpose each living entity has, which probably is controlled by itself. We should allow teleological considerations to permeate research in molecular biology as it is now permeated with concepts of information transfer. Actually, teleological considerations already appear, although veiled, in molecular biology. For example, when one designs the (tertiary) structure of an enzyme so that it will fit the specific substrate and the specific function, then one sees how physico-chemical characterization data will support or disprove such structure. Research of this type, amenable to verification by observation, should be rich with suggestions for further experiments and knowledge, and thus should be within the scientific domain. But, whether this would bring us to the understanding of the biological urge, of course, I cannot say.

SYNTHESIS OF COMPLEX ORGANIC COMPOUNDS FROM SIMPLE PRECURSORS: FORMATION OF AMINO-ACIDS, AMINO-ACID POLYMERS, FATTY ACIDS AND PURINES FROM AMMONIUM CYANIDE

By Prof. C. U. LOWE*, M. W. REES and Dr. R. MARKHAM, F.R.S.
Agricultural Research Council Virus Research Unit, Cambridge, England

EXAMINATION of simple chemical systems, reacting under conditions comparable with those which may have existed at the time life on Earth began, has indicated that many amino-acids are synthesized from such simple precursors as methane, nitrogen, hydrogen and water. The relation of these experiments to the origin of terrestrial life depends for interpretation on two postulates proposed by Oparin[1]: (*a*) primitive life was heterotrophic, obtaining simple metabolic requirements from the environment rather than by internal synthesis; (*b*) the environment in which organic synthesis obtained was reducing in nature, a condition at variance with the present oxidizing environment. In contrast, hydrogen is still the principal constituent of space, and several distant planets appear to have atmospheres rich in ammonia and methane. A scheme to explain the evolution of an oxidizing atmosphere to replace the primitive terrestrial reducing environment has been proposed and correlative deductions reviewed in detail[2].

Synthesis of amino-acids under possible primitive Earth conditions appears to be successful so long as the medium is reducing[3–9]; but under oxidizing conditions the products are negligible whether a cyclotron generating 40 MeV (ref. 10) or a simple sparking device[4] supplies energy.

Miller[3] examined synthesis of complex organic molecules in a reducing environment under simulated primitive Earth conditions. A continuous 60,000-V spark was produced in a sealed vessel containing methane, ammonia, water and hydrogen, and after one week he found a variety of amino, hydroxy, and aliphatic acids in the reaction mixture. He demonstrated[7] that the first reaction products appeared to be hydrocyanic acid and aldehydes and that the synthesis of amino-acids could be directly related to the formation and subsequent disappearance of these. The significant role of hydrocyanic acid in this reaction was demonstrated experimentally, for added hydrocyanic acid led to a doubling of the yield of glycine.

* Present address: Department of Pediatrics, University of Buffalo, 219 Bryant Street, Buffalo 22, N.Y.

Recently, Kliss and Matthews[11] have proposed a unique role for hydrocyanic acid in the synthesis of complex biochemical molecules.

Oro *et al.*[8] examined the products formed by interaction between hydroxylamine hydrochloride and formaldehyde at 80°–100° for 50 h in the absence of sparking. They found that hydrocyanic acid and ammonia were produced and participated in the synthesis of many of the same amino and aliphatic acids identified by Miller. Afterwards, Oro and Kamat[9] investigated the compounds formed from hydrocyanic acid and 3 N aqueous ammonia maintained at 70° for 25 days. By use of paper chromatography they inferred the presence of glycine, alanine and aspartic acid. The identification of adenine in a similar reaction mixture has also been reported[12,13].

The geochemical speculations of Urey and Oparin suggest conditions under which complex organic molecules may have been synthesized and the experiments of Miller and Oro support their hypothesis. Nevertheless, the existence of organic molecules on the primitive Earth would not *per se* lead to organization of these molecules, a prerequisite for the appearance of complex systems of the types found in living organisms. Some evidence for polymer formation is available. Fox reported[14] that many amino-acids undergo spontaneous condensation at temperatures above 150° to yield polypeptides in the presence of an excess of acidic amino-acids. In contrast, the alkaline *p*H of aqueous ammonia is suitable for the polycondensation of both glycine amide[15] and glycine at 100° (ref. 16).

Using a variety of methods, we have examined the products formed when hydrocyanic acid reacts with aqueous ammonia at 90° for 18 h. Our results not only confirm the reports of Oro *et al.*[12–14] concerning the appearance of adenine, glycine, alanine and aspartic acid, but also extend considerably the number of products synthesized. The principal products are complex substances containing amino-acids and unidentified compounds in a bound form which can be released by either acid or alkaline

hydrolysis. After hydrolysis at least 75 ninhydrin reacting compounds appear.

In 9 experiments 1·5 moles of liquid hydrocyanic acid (commercial material containing 0·2 per cent oxalic acid as a stabilizer) were added to 1 l. 1·5 M aqueous ammonia. The oxalic acid produced no obvious effect on the reaction, for the types of products obtained did not differ substantially from those found in a single successful experiment with gaseous hydrocyanic acid.

On addition of liquid hydrocyanic acid to aqueous ammonia, the solution turned amber almost immediately and at the end of the heating period the reaction mixture contained a large amount of amorphous, dense, black material which was removed by centrifugation and amounted to 30–40 g/l. (This complex, and some subsequent complexes, are referred to in the text as polymers. This term is used merely for convenience and is not meant to imply knowledge of the intimate chemistry of these molecules.) The quantity formed appeared in part to be a function of the amount of liquid hydrocyanic acid added. A portion of the supernatant solution was taken to dryness in a rotary evaporator. The residue was extracted with warm water and any insoluble material discarded. Part of the aqueous extract taken to dryness was hydrolysed by heating in constant boiling hydrochloric acid for 24 h at reflux. This represented a 'total hydrolysate'. Another portion of the aqueous extract was placed on an 80 cm × 1 cm column of '*IR* 120' in H^+ form. The large polymers were eluted with water. The free amino-acids and small polymers were retained, and were eluted without fractionation by 2 N aqueous ammonia. After removal of ammonia these were refluxed with hydrochloric acid. Portions of these three fractions (the unhydrolysed aqueous extract, total hydrolysate, and the fraction retained by the resin column) were analysed on an automatic amino-acid analyser (Spinco-Beckman, model 120) by the method of Moore, Stein and Spackman[17]. The results of two experiments are presented in Table 1.

In the unhydrolysed sample the presence of a large number of small complexes interfered with resolution on columns but the positions of glycine, alanine and urea were sufficiently certain for estimation of quantity. In

§ Absorbed on charcoal; eluted and analysed by paper chromatography and by amino-acid analyser.

Exp. 1 about 7 per cent and in Exp. 6 about 14 per cent of the glycine formed was present as free glycine, the remainder occurred in complexes. The polymers present in the crude material contained molecules which on hydrolysis produced urea. For example, in Exp. 2, in comparison with the untreated sample, the hydrolysed portion contained more than twice as much urea.

A sample of a total hydrolysate was desalted electrolytically. One portion was chromatographed (Fig. 1) and another treated with urease. The ammonia evolved after 1 h represented about 50 per cent of the urea found to be present by column chromatography.

One total hydrolysate was treated on a 20 × 1 cm column of 'Dowex 2 × 10' in OH^- form; the material retained by the resin was eluted with N hydrochloric acid and was then fractionated on ion-exchange columns by volatile acids as described by Hirs, Stein and Moore[18,19]. Appropriate fractions were pooled, concentrated to dryness, and examined either by paper chromatography or the automatic amino-acid analyser using appropriate markers. Products identified by these means are listed in Table 2.

A total hydrolysate representing 50–400 ml. of original reaction mixture was sequentially treated on columns containing 'Dowex 50' in H^+ form, 'Dowex 2' in OH^- form and finally charcoal. The constituent amino-acids of the eluate could be resolved on the automatic amino-acid analyser. When an amino-acid was tentatively identified by the elution time, a second analysis with a known amount of marker amino-acid added was performed and the shape of the curves were compared for coincidence of the two samples. The amino-acids listed in column one of Table 2 were each identified in this manner. Paper electrophoresis in conjunction with special colour reactions, for example, Sakaguchi reaction for arginine and guanidine[20], were also used. Leucine and isoleucine were adsorbed on charcoal and could be eluted by 20 per cent acetic acid with 5 per cent (w/v) phenol. The amino-acids in the eluent from charcoal were identified both by paper chromatography and the automatic amino-acid analyser.

In several experiments, glycine or alanine labelled with carbon-14 (40 μc., containing 800 μg of carrier) were added to the aqueous ammonia before the addition of hydrocyanic acid. In large part, these were found incorporated into polymers that were not retained on a column of '*IR* 120' in H^+ form. The water eluate was fractionated and the tubes containing these polymers could be found by detecting radioactivity. In general, two radioactive peaks were observed, polymer I and polymer II. The effluent fractions containing these were pooled separately, and after concentration were further treated on a column of 'Sephadex, medium, *G*-25', 40 × 1 cm. The polymers were eluted with water and dried. A portion of this dry material was examined by paper electrophoresis, using a pyridine–acetic acid buffer, *p*H 6·5, at 36 V/cm. From 7 to 10 bands were shown to be present by chlorination[21,22], and those containing radioactive isotopes were located by autoradiography. Three distinct radioactive bands were found in polymer I. These were eluted from the paper with 1 N aqueous ammonia, dried, hydrolysed in 6 N hydrochloric acid and analysed for amino-acid constituents. Table 3 compares the composition of polymer I obtained from two separate experiments with that of the hydrolysed black polymer of the original reaction mixture and the three radioactive polymers separated by electrophoresis.

The black polymer contained several amino-acids, including glycine and a compound yielding urea on hydrolysis. Polymer I contained amino-acids such as serine and amino-acid *d* which were not found in the radioactive polymers resolved from it by electrophoresis. The three radioactive polymers differed from each other and had characteristic ratios of glycine to alanine.

When ^{14}C-methionine was added to the aqueous ammonia prior to the addition of hydrocyanic acid, it was incorporated into a polymer which corresponded in its behaviour on ion exchange and 'Sephadex' columns to polymer I. This suggested that formation of polymers occurred after synthesis of amino-acids and by implication that some dehydrating mechanism was operative in the reaction mixture.

The addition of hydrogen sulphide to the reaction mixture produced major alterations in the patterns of products and we are attempting to isolate sulphur-containing amino-acids.

Besides the ninhydrin reacting substances, other compounds were obtained and several identified. We were surprised at the complexity of the mixture as revealed by ultra-violet light (260 mμ) on a chromatogram run in isopropanol–ammonia; the combined absorbing and fluorescent bands numbered at least 50. Substances with the chromatographic behaviour and ultra-violet absorption spectrum of adenine and hypoxanthine could be found in the total hydrolysate. The position of adenine on a paper chromatogram was found by adding a small amount of ^{14}C-adenine on paper to the edge of a band of hydrolysate, prior to chromatography. The spot was identified by autoradiography and the region cut out,

leaving behind the marker. The eluted material was further purified by repeated chromatography and identified by means of absorption spectra and paper electrophoresis. The yield was approximately 1 μmol/l. of reaction mixture. By use of similar techniques several attempts to find guanine were unsuccessful.

An ether extract of a dried portion of the total reaction mixture was examined by paper chromatography using an ethanol–ammonia solvent system. At least three spots behaving as fatty acids were resolved. The presence of formic acid was inferred by mobility and reaction with ammoniacal silver nitrate.

These observations indicate that heating aqueous ammonium cyanide produces a variety of ninhydrin reacting compounds as well as polymers containing these compounds. It is probable that the amino-acids are a racemic mixture, since preliminary observations have failed to demonstrate optical activity. The final verification of these substances will be dependent on isolation and identification using classical chemical techniques. We have no data on the structure of the polymers nor knowledge as to whether they are linear. From a single specimen examined by infra-red spectroscopy the presence of peptide bonds could be inferred.

These experiments provide evidence for a consistent, if not exclusive, hypothesis for primitive Earth synthesis of complex organic substances and macromolecules. A major problem on the primitive Earth concerns persistence of the original organisms. Not only was it necessary to provide the constituent materials but also a medium suitable for survival and multiplication. If at any period in recent cosmic time appreciable quantities of ammonium cyanide existed in the Earth's atmosphere, it is obvious that there would have been ample supplies of organic components which would fulfil these functions.

SYNTHESIS OF ADENOSINE TRIPHOSPHATE UNDER POSSIBLE PRIMITIVE EARTH CONDITIONS

By Dr. CYRIL PONNAMPERUMA*, Dr. CARL SAGAN† and RUTH MARINER

Exobiology Division, National Aeronautics and Space Administration, Ames Research Center, Moffett Field, California, and Department of Genetics, Stanford University School of Medicine, Palo Alto

IT has been suggested that the pre-biological synthesis of nucleoside phosphates on the primitive Earth was a consequence of the absorption of ultra-violet light by purines and pyrimidines in an appropriate aqueous medium[1,2]. The basis for this suggestion is as follows:

Even the simplest living organisms are statistically unlikely aggregations of organic molecules. The improbability of contemporary organisms is extracted from the field of possibilities through natural selection. But before the advent of self-replicating systems, natural selection as we understand it to-day could have played no such part. The origin and subsequent replication of life must therefore have involved molecules preferentially produced in the primitive environment. Such a view is implicit in the early works of Haldane[3] and Oparin[4]. While it is possible that the fundamental molecular basis of living systems has itself evolved, the simplest working hypothesis holds that the molecules that are fundamental now were fundamental at the time of the origin of life. The production of amino-acids, purines, pyrimidines and pentose sugars under simulated primitive conditions during the past decade lends support to this hypothesis.

There are, however, still several molecular species the involvement of which in the origin of life remains to be demonstrated. Chief among these are the nucleoside phosphates. Adenosine triphosphate (ATP) is the 'universal' energy intermediary of contemporary terrestrial organisms, and one of the major products of plant photosynthesis. The need for its production in primitive times was first emphasized by Blum[5]. Guanosine triphosphate has recently been implicated as the energy source for peptide linkage[6]. The deoxynucleoside triphosphates are the precursors for contemporary DNA biosynthesis[7]. To the extent that the origin of DNA plays a fundamental part in the origin of life, the abiogenic synthesis of deoxynucleoside triphosphates seems indicated[2]. Several fundamental coenzymes of intermediate metabolism and plant photosynthesis (CoA, DPN, TPN, FAD) are nucleoside phosphates. All these molecules contain purines or pyrimidines which have strong ultra-violet absorption maxima near 2600 Å. The possibility then arises that the absorption of ultra-violet photons by purines and pyrimidines provided the bond energy for the synthesis of nucleoside phosphates in primitive times; and it is therefore of some interest to investigate the ultra-violet transparency of the early terrestrial atmosphere.

There is evidence from astronomy[8,9] that the Earth's atmosphere was reducing at the time life first arose. Laboratory experiments have shown that it is far easier to synthesize organic matter under reducing than under oxidizing conditions[10–12]. The molecules O_2 and O_3 are thermodynamically unstable in an excess of hydrogen, and the principal sources of the ultra-violet opacity of the present terrestrial atmosphere cannot have then been present. The ultra-violet absorption which did exist arose from intermediate oxidation state molecules, principally aldehydes and ketones. In experiments in which electrical discharges were passed through simulated primitive atmospheres, the only aldehyde or ketone

produced in high yield was formaldehyde[13]. Nevertheless, the production of some acetaldehyde[14] and acetone can be expected. Formaldehyde absorption extends longwards of about 2900 Å. Acetaldehyde and acetone absorb throughout the 2400–2900 Å region. Ammonia, acetylene, and other molecules absorb shortwards of 2400 Å.

Therefore, the question of the transparency of the primitive terrestrial atmosphere near 2600 Å turns mainly on the unknown early abundance of CH_3CHO and CH_3COCH_3. Because of the relatively low acetaldehyde and acetone yields in simulation experiments, and because of possible independent biological indications of high ultra-violet fluxes in primitive times[2], it seems likely that the early reducing atmosphere was at least slightly transparent between 2400 and 2900 Å. From models of the evolution of the Sun, and an integration of the Planck function, the ultra-violet flux of wave-length $2900 \text{ Å} \geqslant \lambda \geqslant 2400$ Å incident on the Earth's atmosphere 4×10^9 years ago is computed to be about 7×10^{14} photons cm^{-2} sec^{-1} (ref. 15). Even with substantial atmospheric absorption, ultra-violet radiation in this window will greatly exceed other energy sources for organic synthesis[16].

The synthesis of purines and pyrimidines which absorb in this wave-length region has recently been accomplished in a variety of primitive Earth simulation experiments. Adenine has been produced by thermal polymerization of 1·5 molar hydrocyanic acid in an aqueous ammonia solution[17]; by 5-MeV electron irradiation of methane, ammonia, water and hydrogen[18]; and by ultra-violet irradiation of a 10^{-4} molar solution of hydrocyanic acid[19]. Guanine also appears to be formed in the last experiment. Another guanine synthesis occurs in the thermal copolymerization of amino-acids[20]. Uracil has been produced by heating urea and malic acid[21].

The yields of purines and pyrimidines are sometimes quite high. In the electron beam irradiation of primitive atmospheres by Ponnamperuma, Lemmon, Mariner and Calvin[18], autoradiography indicates that the substance produced in highest yield is adenine. Thus it appears possible that ultra-violet light passing the 2400–2900 Å partial window in the primitive terrestrial atmosphere was strongly absorbed by purines and pyrimidines in the early oceans.

The production rates of organic molecules from reducing atmospheres suggest that the primitive oceans were about a 1 per cent solution of organic matter[2,9]. In addition to purines and pyrimidines the pentose sugars, ribose and 2-deoxyribose can be expected to be present. The laboratory production of 2-deoxyribose has been achieved through the condensation of formaldehyde and acetaldehyde, or of acetaldehyde and glyceraldehyde in aqueous salt solutions[22]. (Indeed, this is an example of a mechanism which keeps the atmospheric aldehyde concentration low.) Both ribose and 2-deoxyribose have been synthesized by either ultra-violet or γ-irradiation of dilute formaldehyde solutions[23]. Phosphates and other phosphorus compounds can be expected in the primitive oceans, even at very early times[24].

It therefore seems of some interest to attempt synthesis of nucleoside phosphates by ultra-violet irradiation of dilute solutions of purine or pyrimidine bases, pentose sugars, and phosphorus compounds, both because of our expectation that such syntheses were easily performed in primitive times, and because ultra-violet irradiation of dilute solutions of adenine and ribose has already produced the nucleoside adenosine[25].

Materials and Experimental Techniques

Adenine-8-^{14}C of specific activity 23·4 μc./mg, adenosine-8-^{14}C of specific activity 7·2 μc./mg, and adenylic acid-8-^{14}C of specific activity 3·1 μc./mg were supplied by Schwarz Bioresearch, Orangeburg, New York. The non-radioactive AMP, ADP and ATP used as carriers were supplied by C. F. Boehringer, Mannheim, Germany. The adenosine tetraphosphate was a gift of Dr. John Moffat of Syntex, Ltd., Palo Alto, California.

The ethyl metaphosphate used in the experiment was prepared by dissolving 150 gm of phosphorus pentoxide in 300 ml. of ethyl ether and refluxing the solution for several hours with chloroform[26]. The excess solvent was removed by evaporation under vacuum, leaving a syrupy residue of ethyl metaphosphate.

The method of irradiation and analysis has already been described[25]. Quantities of the labelled adenine, adenosine and adenylic acid, varying from $1{\cdot}5 \times 10^{-6}$ to $1{\cdot}5 \times 10^{-5}$ moles in various experiments, were sealed in aqueous solution in 'Vycor' tubes with approximately stoichiometric quantities of ribose, phosphoric acid or polyphosphate ester, as shown in Table 1. The final concentration of base nucleoside and nucleotide in each solution did not exceed 10^{-3} moles/l. The solutions were irradiated by four General Electric ultra-violet germicidal lamps, type 782*H*-10, which emit 95 per cent of their light in the mercury resonance line at 2537 Å. The 'Vycor' glass of which the tubes were made transmitted 80 per cent of light of this wave-length. During a 1-h irradiation, the sample absorbed a total of $\sim 10^6$ ergs. During the irradiation the ambient temperature of the samples was $40° \pm 2°$ C.

The reaction products were first analysed by paper chromatography, autoradiography and ultra-violet absorption studies. An aliquot of the reaction products was spotted on a Whatman No. 4 paper and the chromatogram run in two solvents, butanol–propionic acid–water[27] and isobutyric-acid–ammonia[28]. The positions of the carriers adenosine, AMP, ADP, ATP and A4P were detected by shadowgrams[29]. Coincidence both in position and in shape between the carriers on the shadowgrams and the radioactivity on the autoradiograph was the chromatographic basis for the identifications. The formation of adenosine has already been reported[25] A further aliquot was chromatographed in two other solvent systems, trichloroacetic acid–acetone[30] and butanol–formic acid–water[31]. Once again there was coincidence between the carrier as outlined in the shadowgram and the radioactivity on the film.

Separations effected using thin-layer chromatography, and ion-exchange chromatography confirmed the result obtained from paper chromatography.

Results

The results of the investigation are summarized in Table 1 and in Figs. 1–4. Four different categories of experiments were performed. In the first the starting material was adenine, in the second adenosine, in the third adenosine monophosphate, and in the fourth adeno-

Figures in brackets show conversion as percentage of starting material. With the techniques used in this experiment the lower limit of detectability was 0·001 per cent.

In Exp. 4 no quantitative estimates were performed as unlabelled ADP was used. The ATP in this case was located by shadowgrams.

sine diphosphate. The conversion of adenine to adenosine, adenosine to adenosine monophosphate, adenosine monophosphate to adenosine diphosphate, and adenosine diphosphate to adenosine triphosphate has been established. Experiments using adenine as the starting material have produced adenosine, AMP, ADP and ATP.

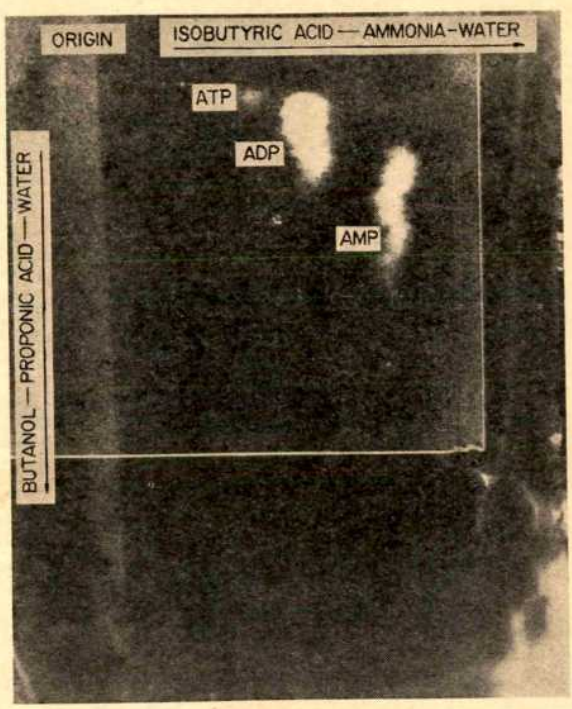

Fig. 4. Shadowgram illustrating the formation of ATP from ADP and ethyl metaphosphate by the action of ultra-violet light. The AMP is a photolytic product

The previously reported experiment showed that adenosine is not produced in detectable amounts in the absence of a phosphorus compound[25]. While adenosine is produced in the presence of both phosphoric acid and ethyl metaphosphate, the nucleoside phosphates were detected only with the use of ethyl metaphosphate. Phosphoric acid was chosen first in the attempt to synthesize the nucleoside phosphates. Ethylmetaphosphate was selected as a possible reagent because of a recent report[26] that it activates carbonyl, hydroxyl and amino groups in organic synthesis. Other phosphorus compounds may also be effective in this synthesis, but they have not yet been investigated.

The yields are given in Table 1 and are further discussed below.

Controls. Two general categories of control experiments were performed to assess two possible modes of biogenic contamination of the reaction products. To test the possibility that the relatively high temperatures (40° ± 2° C) attained by the 'Vycor' tubes during ultra-violet irradiation stimulated the metabolic activities of micro-organisms in the reactants, we placed control tubes at these same temperatures for comparable periods, but without ultra-violet irradiation. In all other respects they were handled and analysed similarly to the irradiated samples. In no case was any yield detected.

An alternative hypothetical source of contamination is the presence in the labelled reactants of micro-organisms which, under ultra-violet irradiation, are photolysed, introducing their metabolic products into the medium. To test this possibility, we introduced into 'Vycor' tubes which had been autoclaved for 45 min at 120° C reactants that had been passed through an autoclaved Seitz filter. These sterile samples were then irradiated with ultra-violet light and analysed. No change in yield was observed. We conclude that the microbiological contribution to the observed yields was negligible.

Discussion

The abiogenic non-enzymatic production of nucleoside phosphates and related molecules under simulated primitive Earth conditions is relevant to the problem of the origin of life. The expected availability of ATP in primitive times suggests that energy was then available in convenient form for endergonic synthetic reactions of large molecules. The question arises why adenosine triphosphate, rather than, for example, the triphosphates of guanosine, cytidine, uridine, or thymidine, were not produced in primitive times and utilized to-day as the primary biological energy currency. There are several possible responses. In primitive Earth simulation experiments under reducing conditions with low hydrogen content, adenine is produced in far greater yield than are other purines and pyrimidines[17–19]. Secondly, no biological purine or pyrimidine has a larger absorption cross-section between 2400 and 2900 Å. Thirdly, adenine is among the most stable of such molecules under ultra-violet irradiation. Finally, the ultra-violet excitation energy is readily transferred, especially by π electrons, along the conjugated double bonds of the molecule; the excited states are very long-lived, and thereby serve to provide bond energies for higher synthetic reaction. All but the first of these properties of adenine derive from the fact that it has the greatest resonance energy of all the biochemical purines and pyrimidines[32,33]. It thus appears that molecules ideally suited for the origin of life were preferentially produced in primitive times.

The yields achieved in these experiments, as shown in Table 1, are relatively quite high. In contrast, quite elaborate methods are ordinarily required for the laboratory synthesis of nucleoside phosphates[34]. For the production of adenosine from adenine, ribose and a phosphorus source, the quantum yield for a 1-h irradiation is $\varphi \sim 10^{-5}$. For production of AMP, ADP and ATP by the use of ethyl metaphosphate, the quantum yields are almost an order of magnitude greater.

It is not now known to what extent the experiments here reported accurately reproduce the environmental conditions in the primitive terrestrial oceans. It can be expected that ethyl metaphosphate was probably not the most abundant phosphorus source; but we do not know how well other, possibly more abundant, phosphate salts may efficiently substitute for ethyl metaphosphate. The irradiation period in these experiments was 1 h. Continued irradiation, with no removal of products, must, by the second law of thermodynamics, ultimately result in lower over-all quantum yields. The influence of inorganic anions on the course and rate of these reactions is largely unknown. Nevertheless, it is of some heuristic interest to compute the production rate of adenosine triphosphate in the primitive terrestrial oceans, where the conditions there were similar to those in the present experiments.

The production rate of ATP in the primitive reducing atmosphere will then be:

$$\frac{d\sigma}{dt} \simeq \frac{Q\varphi\mu}{4N_A} \text{ g cm}^{-2} \text{ sec}^{-1}$$

where Q is the ultra-violet photon flux for 2400 Å $\leqslant \lambda \leqslant$ 2900 Å, is the quantum yield, μ is the molecular weight of ATP, and N_A is Avogadro's number[15]. Taking $Q \sim 7 \times 10^{14}$ photons cm^{-2} sec^{-1}, [15]$\varphi \sim 3 \times 10^{-5}$, and $\mu \sim 550$, we derive:

$$\frac{d\sigma}{dt} \simeq 5 \times 10^{-12} \text{ g cm}^{-2} \text{ sec}^{-1}$$

A feeling for the magnitude of this figure can be obtained by computing the steady-state population of micro-organisms over the entire globe that could be maintained by this quantity of abiologically produced adenosine triphosphate. That is, we assume that the primitive Earth is populated by obligate heterotrophs that obtain all their energy from abiologically synthesized ATP. We will obtain a mimimum population if we assume that the number of ATP molecules required for each replication and the doubling time per cell have values characteristic of typical contemporary organisms. Taking values for *Eschericia coli* of 10^9 ATP molecules per cell for each doubling, and a doubling time of 1 h, we find the required ATP production rate to maintain one cell must be $2{\cdot}5 \times 10^{-16}$ g sec^{-1} cell^{-1}. The steady-state population of micro-organisms that can be maintained over the entire globe by the abiological synthesis of ATP is then 2×10^4 cells/cm^2 column of ocean. This estimate is, of course, extremely approximate. The assumptions that all the ultra-violet light is transmitted by the atmosphere, that it is all absorbed by adenine in the ocean and that the quantum yields used in the ethyl metaphosphate experiments are applicable to the primitive environment probably increase the derived steady-state cell population; while the assumptions that the ATP requirement and doubling time for organisms are the same as for *E. coli* probably decrease the derived steady-state cell population over the true value. Nevertheless, this calculation does suggest that abiogenic ATP production by ultra-violet light in primitive times may have supported quite sizable populations of micro-organisms on the primitive Earth.

Such abiogenic production of ATP is, in effect, photosynthesis without life. One striking conclusion that has emerged from recent work on the mechanism of terrestrial plant photosynthesis is that the production of ATP is the primary, and most primitive, function of the photosynthetic apparatus[35,36]. The experimental results of the present article permit us to understand why this might be so. With rather efficient abiogenic synthesis of so ideal an energy currency as ATP in the primitive environment, the transition from a reducing to an oxidizing atmosphere must have had profound results.

The transition was at least partially initiated by the ultra-violet photodissociation of water vapour in the high atmosphere, and the selective escape of hydrogen to space[8,37]. The ozone concentration of a planetary atmosphere depends approximately logarithmically on the oxygen concentration, down to a certain lower limit of the oxygen concentration[38,39]; thus the steady-state production of even 10^{-4} or 10^{-5} of the present oxygen concentration would have produced enough ozone to diminish the ultra-violet flux in the 2400–2900 Å partial window, and make the rate of ultra-violet synthesis of ATP decline. A premium was then placed on organisms with the ability to utilize visible light for ATP synthesis. One can imagine the metabolism of the primitive organisms to be so keyed to the availability of ATP that the first visible

photosynthetic apparatus evolved would be adopted by all subsequent life forms.

The precise mechanism of synthesis has not yet been investigated. Ultra-violet excitation of adenine accounts for the adenosine synthesis, but the participation of phosphorus compounds in the reaction is obscure. Synthesis of nucleoside phosphates must be more indirect, since it is difficult to imagine the excitation energy being transferred across the ribose molecule, which has no conjugated double bonds. Alternative possibilities, such as the production of activated adenine or ribose phosphates, remain to be investigated.

Further investigation of so far unidentified chromatographic features should both help clarify the mechanisms of synthesis and cast light on other possible prebiological organic reactions. Ultra-violet irradiation of solutions of deoxyribose purines or pyrimidines, and phosphate compounds may have some relevance for the problem of polynucleotide origins.

Bio-assay. To establish whether the ATP synthesized by us was biochemically active, a luminescence assay was performed using dehydrated firefly tails[39]. The method described by Strehler and Trotter was used. (Firefly tails were supplied by Schwarz Bioresearch, Inc., Mount Vernon, New York.) The intensity of luminescence was measured by a Turner fluorometer. The decay curve of the luminescence was identical with that of an authentic sample of ATP. The concentration of ATP in the solution used, as determined by this method, corresponded within the limits of experimental error to the value obtained by spectrophotometric measurements.

One of us (C. S.) thanks Drs. Joshua Lederberg, Matthew Meselson and Jerome Schiff for helpful discussions, and the partial support of his work by the National Aeronautics and Space Administration We also thank Dr John Moffatt for the gift of a sample of adenosine tetraphosphate.

PREDICTION OF FUTURE SUNSPOT CYCLES

By D. G. KING-HELE
Space Department, Royal Aircraft Establishment, Farnborough

THE dates and intensities of the next few sunspot maxima and minima need to be known in order to predict the lifetimes of present and future satellites (since upper-air density varies greatly with solar activity), to plan future telecommunications, to decide the best dates for international geophysical projects, and to forecast the years when astronauts who venture outside the Earth's atmosphere are least likely to meet lethal streams of charged particles from the Sun. Unfortunately, "no satisfactory method of extrapolating sunspot numbers beyond the present cycle has been found"[1], and predictions of the present cycle[2–5] have not been accurate. The object of this article is to direct attention to a 7-cycle recurrence tendency in rise-time and its possible use in prediction.

Since the regular cycle of solar activity, with period 8–15 years, has persisted for many centuries, the forces controlling the variation are likely to be partially determinate. If so, the time-interval which might be expected to show the greatest regularity is the rise-time t_R—the time for the rise from minimum to maximum activity. Fig. 1 gives values of t_R from ref. 6 for each of the past 15 cycles, from 1788 onwards, plotted against the year in which sunspot maximum occurred. (Records for earlier cycles are less reliable.) Fig. 1 shows that the values of t_R for 1788–1870 (broken line) have an identical up-and-down sequence to those for 1870–1947 (unbroken line), thus indicating a 7-cycle recurrence tendency. If the

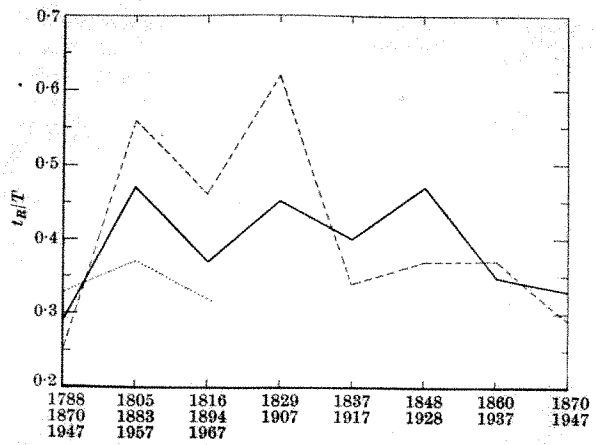

Fig. 2. Time of rise expressed as a fraction of the complete cycle
– – –, 1788–1870; ——, 1870–1947; ····, 1947–1967, predicted

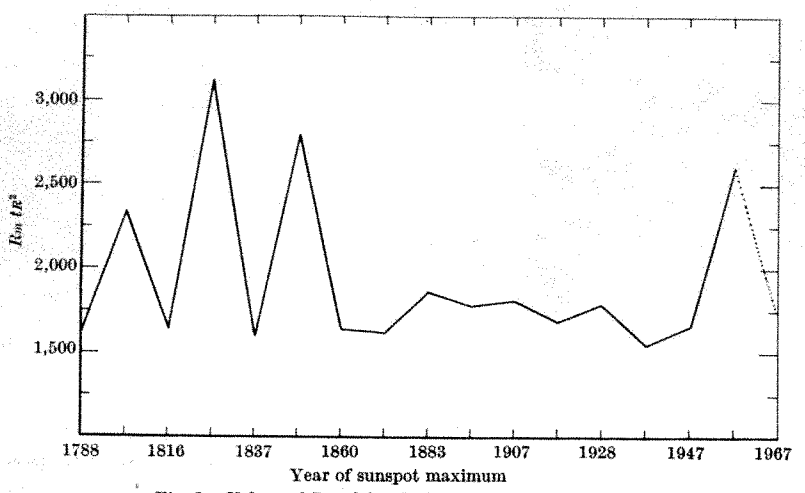

Fig. 3. Values of $R_m t_R^2$ for the last sixteen sunspot cycles
····, prediction

regularity apparent in Fig. 1 persists, the rise-time for the next solar cycle (maximum in 1967) should be about 3·4 years.

Fig. 2 shows t_R expressed as a fraction of the total cycle-length T. Again, the pattern for the years 1788–1870 is the same as for 1870–1947, except that the value of t_R/T for the 1860 cycle is equal to that for the 1848 cycle, instead of being lower. This semi-exception to the rule could, however, be eliminated by taking the 1856 minimum, which was rather indefinite, as a month or two later than the official date of 1856·0 (a change which would not be unreasonable, since sunspot numbers were zero throughout May 1856). If the regularity apparent in Fig. 2 continues, the values of t_R/T for the next two sunspot cycles should be near those indicated by the dotted line: if so, the present cycle would last 9·7 years, declining to its minimum at about 1964·0. This prediction (which makes no use of any information later than 1958) agrees quite well with present estimates, based on short-term extrapolation of current values, that the next minimum is likely to be in 1964. If the values in Fig. 2 are right, the next sunspot cycle should last 10·6 years, having a maximum at 1967·4 and a minimum at 1974·6. (The cycle after that should last 10·0 years, with maximum at 1978·3 and minimum at 1984·6).

The maximum number of sunspots during successive cycles varies widely and shows no such obvious recurrence tendencies as t_R: a 7-cycle recurrence tendency was suggested by Schove[5] on the basis of data given by Gleissberg[7], but failed to show itself in the current sunspot cycle; the 169-year recurrence tendency demonstrated by Anderson[2] also failed in the current cycle. The Zurich sunspot relative numbers[6] show that the highest smoothed monthly number R_m has increased almost linearly in the past four cycles, from 78 in 1928 to 201 in 1957: the 1947 maximum (152) was equal to the previous highest (in 1778) and the 1957 maximum was by far the highest ever recorded. If prediction is to be successful, the uniqueness of these last two cycles must be destroyed and a parameter which exhibits a more uniform trend must be found. Fig. 3 shows values of $R_m t_R^2$, which has the remarkable property of remaining almost constant, at 1700 ± 150, during 9 cycles from 1860 until 1947, though R_m varied by a factor of nearly $2\frac{1}{2}$. In 1957, $R_m t_R^2$ showed a large increase, but since such increases have never before been maintained for two cycles in succession, the value of $R_m t_R^2$ seems likely to return to about 1750 for the 1967 cycle, giving a maximum sunspot number of about $1750/3{\cdot}4^2$ or 150 in 1967—much the same as in 1947. This estimate is in agreement with that of Minnis[1].

These predictions are, of course, disputable. But independent estimates of this kind seem to be needed if the uncertainty which hinders planning in all solar–terrestrial sciences is ever to be dissipated: for example, it would not have been necessary to bring forward the date of the International Years of the Quiet Sun if it had so happened that some credence had been given to the foregoing predictions, which could have been made in 1958.

I thank Mr. W. R. Piggott, of the Radio Research Station, Slough, for suggesting relevant references.

THE ROYAL RADAR ESTABLISHMENT

ON May 24–26, the Royal Radar Establishment, Malvern, was opened to the Press and invited visitors from industry, universities and other Government organizations. The Establishment has not staged such a comprehensive display since, as separate Establishments before the amalgamation in 1953, Telecommunications Research Establishment and Radar Research and Development Establishment held open days in 1948 and 1949.

For administrative purposes the Royal Radar Establishment is organized into five technical groups covering physics, electronics, airborne radar, guided weapons and ground radar. In addition, there are supporting departments in engineering and experimental flying. The basic research activities of the Establishment, which form the main subject of this article, are carried out primarily (but not exclusively) in the physics and electronics groups.

It was possible to discern in the 45 listed exhibits some family resemblances to the Telecommunications Research Establishment of 1948, in spite of the revolutionary developments in electronics over the past 15 years. Thus,

Fig. 1. Map of England by sideways-looking radar. Note the major urban areas. Scale: 60 nautical miles

in 1948, 1 cm was a short wave-length and 3μ (the lead sulphide photo-detection limit) considered far infra-red, but the need to close the gap was uppermost in many minds. The gap is now closed. By the use of various doped semiconductors, notably indium antimonide in a magnetic field at helium temperatures, the Establishment has developed photoconductive detectors spanning the entire infra-red spectrum up to 1 or 2 mm wave-length while essentially conventional microwave receivers have been pushed down to 1 mm primarily by high-precision engineering of which the Establishment can be justly proud. Three decades of the electromagnetic spectrum now lie open for exploitation—for spectroscopy, for plasma physics, for radar. Instrumentation for far infra-red and sub-millimetre spectroscopy was on show, as was the use of high-speed sub-millimetre detectors in plasma investigations. The latter programme is in support of work at the Culham Laboratory of the U.K. Atomic Energy Authority and it was shown how plasma densities and temperatures, as a function of time, can be deduced from emission measurements on magnetically contained plasmas.

With this background, a significant effort at the Royal Radar Establishment on masers and lasers might have been expected. Microwave masers are now primarily a device development rather than a research activity, and formed part of an exhibit showing the impressive improvements made in radar receiver noise performance through the use of improved crystals, parametric amplifiers and masers. With lasers some exploratory applications work is under way—a rudimentary ranging set, using a *Q*-switched ruby laser, was shown—but most of the work is of a more basic nature. The Establishment research on lasers is concentrated on solid-state lasers, for example, ruby, CaF_2, $CaWO_4$, etc., where the problems are at least as much in crystal growth as in optics. The physics group has, over the past ten years, slowly built up a materials section to provide first semiconductor and now laser crystals to meet their various needs. The supply of high-quality crystals, however, throws up new research problems on crystal growth and the results from the investigation of, for example, constitutional supercooling and the 'facet' effect in melt grown crystals were on display, together with related work on vapour phase growth.

Perhaps no single development of the past fifteen years has influenced electronics as much as the miniaturization, and now microminiaturization, permitted by the use of solid-state devices. Two (working) transistors on a pin-head and a four-colour reproduction of the coat of arms of the Royal Radar Establishment by selective etching of an oxide film on a silicon crystal illustrated the power of available techniques. For military electronics at least, all future circuit assembly seems destined to take place under a microscope or in an evaporation chamber, and circuits must be designed with this end in view. An example of this trend —a 60-Mc/s bandwidth amplifier—was on show. Some of the recent developments in computer components—notably cryotrons, magnetic films and tunnel diodes—were exhibited, both as devices and for their basic physical interest. Thus the use of tunnel diode pairs in a time discriminator circuit for non-destructive interrogation of ferrite cores was shown, and an investigation of the effect of magnetic fields up to 150 kilogauss on InSb tunnel diodes. For computers, miniaturization is synonymous with high speed and low cost, at which evaporated devices such as cryotrons are aimed. The demonstrations included equipment for displaying switching transients in magnetic films for switching times of the order of 1 nanosecond, at which speeds the close proximity of components is essential.

The open days represented, in a sense, the baptism of the automatic computer of the Royal Radar Establishment which is a one-address machine with 36-bit words and, at present, an 8,000-word core store. Basic operations (for example, shifting) take about 300 nanoseconds each. The standard input language is *ALGOL*. In common with many modern machines *RREAC* can tackle three programmes simultaneously by time sparing, and this facility formed the basis of the exhibit: while working on a more serious problem, *RREAC* played the game of kails against all challengers.

Another large installation on view to the public for the first time was the High Field House, which contains Bitter solenoids for the production of steady magnetic fields up to 130 kilogauss and the associated equipment to provide power at a rate up to 2·7 MW. The energy is obtained from a large bank of submarine batteries. Present work, which was on show, includes the examination of those superconductors having a β-tungstate structure which show superconductivity even in high magnetic fields. Apart from the 130 kilogauss facility, the Establishment had a number of other large magnets on show. This magnet, which is limited by its core to about 35 kilogauss, is a good example of the work of the engineering department. At present, and for the open days, it is being used for magneto-optical investigations of semiconductors.

Radio-astronomy and satellite tracking proved popular exhibits in spite of the travelling (about 10 miles and 3 miles respectively) involved. The radio telescope at Defford, near Malvern (*Nature*, 190, 1150; 1961) has been used as an interferometer at 610 Mc/s on nearly 100 radio sources and very accurate positions have been derived for about 30 of these. Used as a radar, the Defford installation has been used to examine meteor echoes at 1,300 Mc/s, and more recently measurements have been made on incoherent scatter by electrons in the upper atmosphere. The satellite tracking equipment on show included a recently erected 45-ft. diameter precision radar tracker and its associated equipment. Though not yet complete, visitors were able to watch the aerial lock on to satellites *Allouette* and *Anna*. Included in the exhibit was a 24-in. diameter *F*1 Schmidt camera which can accurately record the position of a satellite or star down to magnitude 9.

An important series of exhibits illustrated the part that the Royal Radar Establishment is playing in the development of a fully integrated air traffic control system. The increasing quantity of air traffic of the present day demands techniques which will match the increasing demands without impairing safety, and it seems that a combination of modern radar with electronic computing techniques may meet the requirements. Experimental systems involving a number of automatic techniques are being investigated at the Establishment and the exhibits showed how simulated situations might be dealt with in a series of exhibits at once elegant and complex.

Many of the exhibits demonstrated the work being carried out to improve the resolution of radar targets against a background of clutter. Pulse compression techniques demonstrated the ability to simulate the effects of short pulses of embarrassingly high-peak power with, in fact, a long pulse of modest peak power. Another showed how it might be possible automatically to compensate for the distortion of a large aerial, for example, in high wind, or under load, and so preserve the accurate profile so essential to accurate angular determination of target direction.

Modern and refined techniques now being made available for airborne use for navigational purposes were on show. These included a new optical line scan technique for aerial photography in which the ground is scanned by a rotating mirror as the aircraft moves forward. The resulting images are transformed into electrical signals which can be used to form a strip photograph. The results obtained with sideways-looking radar techniques were shown, and Fig. 1 shows a map of England and Wales which has been built up from a series of flights which might well be over cloud or by night. High resolution reconnaissance requires high resolution display equipment. A fully resolved television picture measuring $2{\cdot}5 \times 3{\cdot}0$ mm and viewed through a microscope proved an eye-catching exhibit.

To conclude this brief account of the Royal Radar Establishment open day exhibits mention must be made of the Establishment's College of Electronics where students take, among other things, the Higher National Certificate and Diploma Courses in Electrical and Electronic engineering. The College was open for inspection, the demonstrations including a gas laser and a 3-cm marine radar. The College, now some fifteen years old, caters for some 180 student-apprentices, and about 100 craft apprentices and for day-release students.

OBITUARY

Prof. J. F. Piccard

The gentle giant, professor emeritus of aeronautical engineering at the University of Minnesota, Jean Felix Piccard, died of a heart attack on January 28, 1963, at the age of seventy-nine.

Prof. Piccard was born January 28, 1884 of French-speaking Swiss parents Hélène (*née* Holtenhoff) of Geneva, and Jules, head of the Department of Chemistry in the University of Basle, Switzerland. He is survived by his wife Jeannette (Ridlon) Piccard, three sons, Donald, John, and Paul, a sister Mme. Paul Lambert of Lausanne and a brother, Dr. Paul Piccard of Lucerne.

Jean and his twin brother, Auguste, attended the Obere Realschule, Basle. After graduation from that school in 1902, Jean Piccard enrolled at the Swiss Institute of Technology in Zurich, took his degree in chemical engineering (1907) and, like his brother, was awarded a doctorate in natural science (1909) from that institution. He received his doctorate in organic chemistry in 1901 as a result of his thesis "The Constitution of Meriquinonique Compounds" which brought him an Institute prize and the silver medal award. He taught at the University of Lausanne during 1914–16, when he was appointed assistant professor at the University of Chicago; but he returned in 1919 to join the staff of the University of Lausanne. Then he returned to the United States and was appointed instructor at the Massachusetts Institute of Technology, until 1929 when he entered private industry as consultant for various organizations. He became a United States citizen in 1931. Afterwards, he worked as head of the Chemical Service Department at the Hercules Powder Co. of Delaware (1929–32). He next assumed the post of research associate at the Bartol Research Foundation, Swarthmore, Pa., during 1933–36. In 1936 Prof. Piccard joined the teaching staff of the University of Minnesota as special lecturer in aeronautics, and attained professorial rank in 1937 from which he retired in 1952 as professor emeritus.

In 1957 Jamestown College, North Dakota, presented him with an honorary doctor of science degree; in 1959 he was honoured by the American Meteorological Society for his pioneer work in scientific stratosphere balloon flight. The University of Strasbourg conferred on him an honorary Ph.D. degree in 1932, and in 1960 he received the United States Distinguished Service Award. He had been named one of Minnesota's 100 "Living Great".

Named the "Mr. Up" of scientific exploration, Prof. Piccard's interest in balloons stemmed from collaboration with Auguste in 1913, when they made the first balloon flight together in Switzerland, and were the first to use a balloon as a physics laboratory. During the First World War, Jean and Auguste served as civilian consultants for the Swiss Army on captive balloons. The 1930's brought his contribution to the forefront when in 1933 Prof. Piccard designed a stratosphere gondola for the Dow Chemical Co., the basis for to-day's gondola design. The following year he ascended in a special balloon piloted by Mrs. Piccard. They took off from the Ford Airport in Dearborn, Michigan, and after attaining a height of 57,579 ft. landed in Cadiz, Ohio. In 1936 he sent up a balloon equipped with a radiosonde set from the University of Minnesota football field. This endeavour proved to be the first known experiment with a plastic non-extensible balloon. One of his helpers on this project was Robert Gilruth, now director of Manned Space Flight Program of the National Aeronautics and Space Administration.

In 1937 Prof. Piccard introduced another 'first' by successfully completing a flight over Rochester, Minnesota, testing the cluster idea of balloons. He made the ascent to about 10,000 ft. in an aerostat, *Pleades I*, using 98

rubber latex sounding balloons fastened to a metal gondola for lift. Of this flight Dr. Gilruth said: "It was a tremendous achievement. For one thing, he used electrically controlled blasting caps to blow off his ballast. Thus he was the first to use pyrotechnics to actuate devices. Now we have 73 such pyrotechnic devices for Mercury capsule".

His interest in high-altitude flight and balloons preceded that of Raven Industries in Sioux Falls, South Dakota; Winzen in South St. Paul; Schjeldahl in Northfield, and General Mills in Minneapolis. He later experimented with 'Cellophane' and other plastic balloons, and helped design the polyethylene *Skylark* series of high-altitude balloons with which the U.S. Air Force sent manned flights to altitudes exceeding 100,000 ft.

Prof. Piccard published many papers on ballooning, and in his earlier specialization, chemistry (organic, inorganic, and physical), and in aeronautical engineering.

His hobbies and interests included sailing, skiing, mountain climbing, riding in 'blimps' and aeroplanes. In regard to this he said: "But to me, riding in a free balloon is the most beautiful sport of all". During his retirement, he and Mrs. Piccard found pleasure in their cabin retreat of a four-acre island in Lake Vermilion. He and Mrs. Piccard were also part-time teachers at St. Paul's Episcopal Day School.

C. C. Chang

NEWS and VIEWS

Royal Society Research Appointments

The Royal Society has made the following appointments in original scientific research: The Tropical Research fellowship has been awarded to Dr. K. Vickerman, of the Department of Zoology, University College, London, to enable him to work on the mechanism of structural and physiological transformation in the life-cycles of trypanosomes. A Stothert Research fellowship has been awarded to Mr. C. N. Hales, of the Department of Biochemistry, University of Cambridge, to enable him to work on the immunochemical investigation of insulin. A further Stothert Research fellowship has been awarded to Mr. P. E. Reynolds, of the Department of Biochemistry, University of Cambridge, to enable him to work on cell-wall synthesis in bacteria, and the effects of antibiotics. The Head Bequest Committee of the Royal Society has awarded the Henry Head Research fellowship to Dr. J. S. Gillespie, of the Institute of Physiology, University of Glasgow, to enable him to continue his work on the automatic innervation of the gut. The appointments take effect from October 1.

Warren Spring Laboratory : Dr. C. C. Hall

Dr. Charles Hall has been appointed director of the Warren Spring Laboratory of the Department of Scientific and Industrial Research at Stevenage. Dr. Hall, at present deputy director of the Laboratory, will succeed the retiring director, Mr. S. H. Clarke, who will take up a post in the Department's Headquarters, with responsibility for supervising the careers of scientific staff in the Department. Both appointments take effect in January 1964. Dr. Hall was born in Croydon and was educated at Beckenham County Grammar School and at Sir John Cass College, University of London, where he graduated (B.Sc.) in 1929 with first-class honours in chemistry; he obtained his M.Sc. in 1930 and Ph.D. in 1934. He joined the Fuel Research Station of the Department of Scientific and Industrial Research in 1930 and was with that Station until it closed down in 1958. During most of the time, Dr. Hall was concerned with the chemistry and technology of the production of liquid fuels from coal. From 1939 until 1958 he was in charge of the Station's largest team working on the Fischer–Tropsch process. After the Second World War he played a leading part in the investigations into the development of the process in Germany. From 1953 until 1958 he was the deputy chief chemist of the Fuel Research Station. In 1959, Dr. Hall was appointed deputy director of the newly-formed Warren Spring Laboratory, which is engaged in research primarily on air pollution, mineral processing and chemical engineering. He was elected a Fellow of the Royal Institute of Chemistry in 1944, was a member of Council from 1957 until 1960 and chairman of the London Section from 1957 until 1959. He was elected a Fellow of the Institute of Fuel in 1954.

International Atomic Energy Agency's Research Laboratories : Prof. Leo Yaffe

Prof. Leo Yaffe (Canada) has been appointed director of the International Atomic Energy Agency's Division of Research and Laboratories. Prof. Yaffe, who took up his post on July 14, was born in 1916 at Devil's Lake, North Dakota. He studied at the University of Manitoba, gaining his B.Sc. in 1940 and M.Sc. in 1941, and received his Ph.D. from McGill University in 1943. He was director of the Radiochemistry Laboratory of McGill University and has been teaching since 1952, and Macdonald professor of chemistry at that University since September 1959. From 1943 until 1952 Prof. Yaffe was project leader in charge of Nuclear Chemistry and Tracer Research with Atomic Energy of Canada, Ltd., Chalk River. Prof. Yaffe was adviser to the Canadian Delegations for both United Nations Conferences on the Peaceful Uses of Atomic Energy at Geneva in 1955 and 1958. His predecessor as director of the Division of Research and Laboratories was Prof. Carlo Salvetti (Italy) until March 1962. In the interim period, Prof. Alexandre Sanielevici (Romania) served as acting director.

Academy of Sciences of the U.S.S.R.

At a general meeting of the Academy of Sciences of the U.S.S.R. a re-organization of the Academy has been approved. Fifteen specialized branches for the guidance of research in the main directions of science have been formed. Each of the previously existing eight branches had covered a very wide range of different fields of learning. Therefore, instead of one biological branch, for example, three new ones have been set up: biochemistry and chemistry of physiologically active compounds; physiology; zoology, botany and evolution. Four new branches, including a branch of nuclear physics and mathematics, have been instituted. A new branch has been set up for the science of the Earth, which unites geologists, geographers, oceanologists, geophysicists, specialists on the physics of the atmosphere, etc. Mstislav Keldysh has been re-elected president of the Academy. Nikolai Semenov, who headed the branch of chemical sciences, has been elected vice-president. Norair Sisakyan, who was the academic secretary of the biological sciences branch, has been elected senior honorary secretary.

Anglo-Russian Exchange of Scientists

Sir Bernard Lovell is visiting Leningrad at the invitation of the Soviet Academy of Sciences. On July 9 he met Vasily Isayev, the Mayor of the City, and other officials, and discussed with them scientific contacts between the Pulkovo Observatory and Jodrell Bank, which, he said, were very useful. Leningrad astronomers supported Sir Bernard's proposal that an exchange of junior scientific personnel should be started. Sir Bernard is planning to familiarize himself with the scientific

achievements of Pulkovo astronomers and to deliver a lecture to them on research carried out at Jodrell Bank. He will discuss with his Leningrad colleagues a programme of scientific exchange and individual observations of interest to both observatories.

Problems of Noise Abatement

THE Minister for Science, Lord Hailsham, said in the House of Lords on July 2 that he had now received the final report of the Committee appointed in April 1960, under the chairmanship of Sir Alan Wilson, to consider the problem of noise, and the Government had already given preliminary study to the recommendations in the report. The Minister of Transport proposed to give effect to nearly all the recommendations of the Committee's interim report on noise from motor vehicles, and new regulations had recently been circulated in draft to the organizations concerned. These regulations would lay down maximum permissible noise-levels for motor vehicles when used on the roads, and would also prescribe the instruments and conditions to be used for roadside tests. The Minister of Aviation would maintain the present strict control over movement of aircraft in and near airports and would continue to support research into ways of reducing aircraft noise at source and to investigate other aspects of the problem. The Ministers of Education and Health would seek to ensure that new schools and hospitals in the close vicinity of airports are designed to minimize noise inside the buildings, and would continue to seek to reduce noise in existing buildings, but the Government was not satisfied that the situation at Heathrow (London Airport) justified the recommendation for grants for sound-proofing private houses there. A number of recommendations relating to the need for additional research, for improved methods of disseminating information about the results of research, and for making industry and the public aware of the need to avoid making unnecessary noise had been accepted and were being implemented. The Medical Research Council and the National Physical Laboratory were co-operating in a joint project, sponsored by the Ministry of Pensions and National Insurance, to survey the effects of industrial noise on the hearing of workers by means of mobile laboratories which will visit factories of various types. Besides recommendations coming within the direct responsibility of the Government, others would be discussed with local authorities and others concerned, and some would require legislation. The necessary consultation would be undertaken as soon as possible.

Research in the Social Sciences

IN a written answer in the House of Commons on June 26, the Home Secretary, Mr. H. Brooke, stated that the other members of the Committee of Enquiry set up under Lord Heyworth's chairmanship (see also *Nature*, **198**, 1041; 1963) would be: Mr. Noel Annam, Prof. C. F. Carter, Sir Austin Bradford Hill, Dame Mary Smieton and Prof. Charles Wilson. The Committee's terms of reference were to review the work at present done in the field of social studies in Government departments, universities, and other institutions, and to advise whether changes were needed in and arrangements for supporting and co-ordinating this research, and it was intended that the Committee's investigation should cover social studies in Scotland as well as in England and Wales.

Output Capacity of Nuclear Reactors in Great Britain

IN a written answer in the House of Commons on July 4, the Minister of Power, Mr. R. Wood, stated that the present output capacity of nuclear reactors in Great Britain was 960,000 kW; by the end of 1964 this was expected to rise to 2,535,000 kW; 1965, 3,100,000 kW; 1966, 3,670,000 kW; 1967, 3,950,000 kW; and 1968, assuming 1 million kW of capacity will be commissioned at Wylfa, 4,950,000 kW.

Smithsonian Institution : Museum of Natural History

A NEW Department of Entomology has been established as the fifth major unit of the Museum of Natural History of the Smithsonian Institution, Washington. The other four Departments are Anthropology, Botany, Geology, and Zoology. Hitherto the entomological activities of the Museum have formed a division of the Department of Zoology. The new Department initially will consist of four divisions: the Division of Neuropteroids (caddisflies, mayflies, dragonflies); the Division of Coleoptera (beetles); the Division of Lepidoptera (butterflies and moths); and the Division of Myriapoda and Arachnida (centipedes, millipedes, and spiders). To-day, the entomological collections of the Museum comprise more than 16,000,000 insects, spiders, centipedes, millipedes, and related creatures. It is the most important and largest such collection in the Western Hemisphere, and, with that of the British Museum (Natural History), the Smithsonian collection is one of the two largest insect collections anywhere. Dr. J. F. Gates Clarke has been appointed head curator of the new Department. He will also serve as acting curator of the Division of Lepidoptera. The Division of Neuropteroids will be headed by Dr. Oliver S. Flint, jun., the Division of Coleoptera by Oscar L. Cartwright, and the Division of Myriapoda and Arachnida by Dr. Ralph E. Crabill, jun.

Abstracts and Indexes in Science and Technology

UNDER the title *Abstracts and Indexes in Science and Technology*, the Borough of Lewisham Library Service has issued an annotated guide to the abstracts, indexes and periodicals containing abstracts in science and technology provided by that Library Service (Metropolitan Borough of Lewisham Library Service. Scientific and Technical Information Service Publication No. 1, *Abstracts and Indexes in Science and Technology—an Annotated Guide to the Abstracts, Indexes and Journals containing Abstracts, provided by the Lewisham Library Service*. Pp. 12. Lewisham, London: Scientific and Technical Library, 1963.) The abstracts and indexes listed cover the bulk of the world's estimated output of 30,000 technical periodicals. A list of *Current Abstracts and Indexes in the Technical and Commercial Libraries of the Manchester Public Libraries*, with a preface by Mr. F. R. Taylor, librarian of the Manchester Technical Library, has also been issued (Manchester Public Libraries. *Current Abstracts and Indexes in the Technical and Commercial Libraries*. Pp. ii+42. Manchester: Technical Librarian, Central Library, 1963. 10*s*. 6*d*.). It contains 287 entries, which are annotated and give the library holdings, coverage, frequency of publication, etc. The entries are arranged alphabetically by title and there is a subject index.

British Cænozoic Fossils

THE first edition of *British Cænozoic Fossils*, published by the British Museum (Natural History) in 1959, was an immediate and deserved success. A second edition of this beautifully illustrated guide to the fossils most commonly found in Britain is now available (*British Cænozoic Fossils (Tertiary and Quaternary)*. Second Edition. Pp. vi+133 (44 plates). London: British Museum (Natural History), 1963. 6*s*.). The plates are unaltered and only minor changes have been made to the text. A useful addition is the provision of references to plate numbers in the fossil distribution lists, and the botanical nomenclature has been brought up to date.

Physics of Electronic and Atomic Collisions

THE third international conference on the "Physics of Electronic and Atomic Collisions" is to be held at University College, London, during July 22–26. Approximately 350 physicists from 21 countries will attend and

contribute 130 papers, relating to elastic and inelastic collision processes involving atoms, simple molecules, electrons and photons. The growth of interest in this field during the past few years, perhaps four-fold, is in part stimulated by power generation, magneto-hydrodynamics and fusion, by the discovery of lasers, and by the need to understand ionizing phenomena in the Earth's atmosphere and in space exploration, as well as problems in astrophysics. However, the central interest remains the development and testing of our understanding of the quantum theory of collisions. In this context it is interesting to note the present spheres of emphasis; the newly discovered narrow resonances in the scattering of electrons by atoms; the anomalous polarization of radiation excited by collision; the exploration of energy-levels in the continuum; the numerous inelastic processes undergone in energetic collisions between two atomic systems; the study of chemical reactions by refined scattering technique; the electron-ion recombination processes in highly ionized gases; and the conditions for the excitation of gases to a state where stimulated emission dominates and the production of coherent radiation by laser action becomes possible. Review papers will be presented by: Sir Harrie Massey, Dr. D. W. O. Heddle and Dr. M. J. Seaton (England); Prof. D. R. Bates and Prof. A. Dalgarno (Northern Ireland); Dr. M. A. Biondi, Prof. R. B. Bernstein, Dr. V. W. Hughes and Dr. C. K. Patel (United States); Prof. C. A. McDowell (Canada). Further information can be obtained from the conference secretaries, Dr. J. B. Hasted and Dr. D. W. O. Heddle, Department of Physics, University College, Gower Street, London, W.C.1.

The Night Sky in August

Full moon occurs on Aug. 5d. 09h. 31m. U.T. and new moon on Aug. 19d. 07h. 35m. The following conjunctions with the Moon occur: Aug. 5d. 23h., Saturn 1° N.; Aug. 10d. 02h., Jupiter 4° N.; Aug. 23d. 05h., Mars 5° S. In addition to these conjunctions with the Moon, Mercury is in conjunction with Regulus on Aug. 2d. 20h., Mercury being 0·6° N. Mercury, Venus and Mars are too close to the Sun for observation. Jupiter rises at 22h. 00m., 21h. 05m. and 20h. 00m. on Aug. 1, 15 and 31, respectively. It is in Pisces, its stellar magnitude is −2·3 and its distance from the Earth on August 15 is 400 million miles. Jupiter is stationary on August 10, after which its motion is retrograde among the stars. Saturn is above the horizon most of the night. It is in Capricornus, reaching opposition on August 13. Its stellar magnitude is + 0·5 and its distance from the Earth on August 15 is 825 million miles. There are no occultations of stars brighter than magnitude 6 visible at Greenwich. The Perseid meteors are active during July 27–August 17, with maximum on August 12, but conditions for observation are unfavourable.

University News: Aberdeen

Two additional chairs, of statistics and education, have been established and will be occupied by the present heads of the departments concerned, namely, Dr. D. J. Finney and Dr. J. D. Nisbet, respectively. The following promotions from lecturer to senior lecturer have been announced: Mr. P. W. Davis (forestry); Dr. W. E. Fraser (geology).

Sheffield

Dr. W. Bartley, at present University demonstrator in biochemistry in the University of Oxford, has been appointed to the chair of biochemistry from a date to be arranged. Dr. A. R. Entwisle has been appointed senior lecturer in metallurgy, and Dr. E. Rothwell senior lecturer in fuel technology and chemical engineering. Dr. I. O. Sutherland has been appointed lecturer in chemistry.

Announcements

Mr. A. Simpson, recently appointed lecturer in aeronautical engineering in the University of Bristol, has gained a Ph.D. degree at the University of Bristol. In so doing he becomes the first holder of the diploma in technology to obtain the Ph.D. of a university.

The second European Anatomical Meeting will be held in Brussels during September 1–5. Further information can be obtained from Prof. P. Dustin, 97 rue aux Laines, Brussels 1.

The conference of the Society for Folk Life Studies will be held in the University of Leeds during September 6–9. Further information can be obtained from J. Geraint Jenkins, c/o Welsh Folk Museum, St. Fagan's Castle, near Cardiff.

The fourth International Congress on Surface Active Substances will be held in Brussels during September 7–12, 1964. Further information can be obtained from the General Secretariat, Fourth International Congress on Surface Active Substances, 49 Square Marie-Louise, Brussels 4, Belgium.

The ninth conference on the European Meat Research Workers, organized this year by the Hungarian Meat Research Institute, will be held in Budapest during September 4–12. Further information can be obtained from the Hungarian Meat Research Institute, Herman Otto ut 15, Budapest 2.

The fourth international conference on "Non-Destructive Testing", sponsored by the British National Committee for Non-Destructive Testing and arranged by the Institution of Mechanical Engineers, will be held in London during September 9–13. Further information can be obtained from the Institution of Mechanical Engineers, 1 Birdcage Walk, London, S.W.1.

The fifth international Biometric Conference will be held in Cambridge during September 9–14. The programme will include sessions on: biometrical genetics; problems of experimentation, mathematical models in biology; multivariate analysis; medicine and bioassay; statistical methods. Further information can be obtained from Dr. R. C. Campbell, School of Agriculture, Cambridge.

The Centennial of Entomology in Canada, sponsored jointly by the Entomological Society of Canada and the Entomological Society of Ontario, will be held at Carleton University, Ottawa, during September 3–6. Further information can be obtained from the Centennial Executive Committee, Centennial of Entomology in Canada, K. W. Neatby Building, Carling Avenue, Ottawa.

A four-week practical course in "Administration and Management of Research and Development", arranged by the Comparative Administration Trust, will be held at Queen's College, Oxford, during September 1–28. The three main topics to be considered are: the nature of the individual and of the team; the teams in their wider context; special problems of science and technology. Further information can be obtained from the Comparative Administration Trust, 30 St. George Street, Hanover Square, London, W.1.

The International Union of Crystallography will be holding its sixth general assembly, international congress and symposia in Rome during September 9–18. The programme will include: a special congress discourse entitled "Crystallography: the Old and the New"; four general lectures; sessions for the presentation and discussion of contributed papers; an exhibition of apparatus and books; symposia on: problems and methods in crystallographic computing; phase transitions in solids; some aspects of lattice dynamics. Further information can be obtained from Dr. W. H. Taylor, Crystallographic Laboratory, Cavendish Laboratory, Cambridge.

GOVERNMENT EXPENDITURE ON SCIENTIFIC RESEARCH, 1962

THE report of the Council for Scientific and Industrial Research for the year 1962 * records gross expenditure in the year ended March 31, 1962, of £16,691,172, compared with £14,467,278 in the previous year, and reduced to £14,378,202 by various receipts from industry and other sources for services rendered, of which £1,120,677 was from other Government departments and £858,170 from industry, £214,143 being received by the National Physical Laboratory. The net increase on 1961 was £1,619,022, and of this, £258,922 is on account of the National Lending Library for Science and Technology, which figures for the first time as a separate item (gross expenditure, £304,249) in the summary of expenditure. The staff again increased, from 6,224 to 6,525. Grants for special researches rose to £2,275,060, compared with £1,495,469 in 1961, and contributions to the European Organization for Nuclear Research remained about £1,359,000, while receipts reduced the contribution of £198,800 to NATO and the Organization for European Co-operation and Development scientific schemes to £63,722.

Postgraduate training awards amounted to £1,289,903 (£1,105,415 in 1961) and the 1,604 new studentships, an increase of 9 per cent, brought the number current to 3,478. Research fellowships increased from 54 in 1961 to 92 in 1962, and there are now 133 current. Of 51 awards for study abroad taken up, 23 were studentships and 28 fellowships, while 8 studentships and 16 fellowships were awarded to assist young British scientists returning from North America; 35 candidates with the diploma in technology obtained awards, compared with 11 in 1961. Of the 3,019 current research studentships, 413 were in biology and biochemistry, 205 in chemical engineering and metallurgy, 899 in chemistry, 128 in electrical and 203 in other fields of engineering, 214 in geology, 57 in the human sciences, 260 in mathematics, and 640 in physics. The advanced course studentships were distributed mainly in mathematics (88), physics (75) and engineering (other than electrical) (70), with 39 in chemical engineering and metallurgy, 29 in human sciences, 28 in biology and biochemistry, 22 in geology, 20 in electrical engineering and 15 in chemistry. All the 73 first-year studentships were again in chemistry, and of the 115 research fellowships, 56 were in chemistry, 29 in physics and 25 in biology and biochemistry, with 10 in geology.

Grants for special researches totalled 724, of which 321 were new, amounting to £9,881,252 in the year ended March 31, 1962; of these, 59 in nuclear physics totalled £3,870,624, 17 in astronomy, £1,045,796, 121 in technology, £1,024,768, and 165 in chemistry, £957,551. The 79 grants in low-temperature and solid-state physics totalled £688,267, 100 grants in biology totalled £535,417, 33 in space research, £520,926, 58 in geology and geophysics, £469,689, 50 in the human sciences, £419,601, and 36 in physics, £328,162. During the academic year 1961–62, the Research Grants Committee considered 500 applications for grants with a total value of £4,204,000, compared with 447 applications valued at £3,156,000 in the previous year, and made 390 grants with a total value of £2,313,000, compared with 362 amounting to £1,961,000 in 1960–61. In addition, five grants were awarded for new major capital projects: £534,200 to the University of Cambridge for construction of a radio-telescope for research under Prof. M. Ryle; £301,000 to the University of Manchester for construction of a 125-ft. steerable radio-telescope for research under Sir Bernard Lovell; and three grants totalling £1,188,000 for nuclear reactors for the University of London as a whole, the Universities of Manchester and Liverpool jointly and the Scottish and Northern Ireland universities. The Human Sciences Committee considered 36 applications with a total value of £232,000 and made 27 awards to the value of £132,000.

With the exception of building research, which decreased slightly from £785,413 gross in 1960–61 to £781,037 gross in 1961–62, and the Geological Survey and Museum, which decreased from £586,640 to £578,969 gross, the increased expenditure was distributed fairly generally over all branches of the Department's work. However, an unexplained jump in receipts by the Tropical Products Institute from £22,300 to £399,472 converted the increased total expenditure on the Institute of £229,751 into a credit of £169,721, an anomaly that seems to call for comment. The major increases are in the expenditure of the National Physical Laboratory (£2,033,109 gross; £1,787,542 in 1960–61), the National Engineering Laboratory (£924,978; £811,164); the National Chemical Laboratory (£409,887; £384,073); road research (£970,403; £872,805); radio research (£320,413; £239,957). For fire research the corresponding figures are £164,438 and £156,130; for forest products research, £194,619 and £185,985; hydraulics research, £232,661 and £203,931; the Torry Research Station, £226,696 and £215,192; the Warren Spring Laboratory, £471,181 and £453,985; water-pollution research, £183,550 and £165,336; and for the Government Chemist's Laboratory, £491,215 and £460,257. Expenditure on headquarters administration decreased from £758,126 in 1960–61 to £615,536, or slightly below the 1959–60 figure.

EDUCATION IN MATERIALS SCIENCE

THE first conference on "Education in Materials Science" and technology in the United Kingdom was held in Banbury during May 18–19 under the general chairmanship of Mr. L. Holliday (Shell Chemical Co., Ltd.). The conference was arranged by the Steering Committee of the Working Party on Materials Science and Technology, set up by the Institution of Chemical Engineers. Some thirty representatives from universities, colleges of advanced technology and industry were invited.

The first session dealt with the situation in materials science in the United States and in Britain and went on to consider possible starting points for materials science courses and research in universities. Sir Harry Melville, secretary of the Department of Scientific and Industrial Research, introduced the subject of the conference and emphasized its importance not only in universities and colleges but also in industry and Government scientific establishments. It was of immediate concern to the Department of Scientific and Industrial Research, which

had to keep new developments in constant review so that finance could be found for worth-while proposals.

Although it was not known what the outcome of the Robbins Committee would be, Sir Harry thought that it was likely that Britain would continue with the three-year undergraduate courses, and because these were now so crowded it would be difficult to introduce in depth the concepts of materials science without risking superficiality in the courses. He thought that this problem would be least serious in metallurgy departments because they have done this kind of work in universities over the years. The limitations of existing courses could be met by the establishment of postgraduate courses, support for which was now provided by his department. Sir Harry considered that one of the serious problems of creating an interdisciplinary subject was to achieve something greater than the arithmetical sum of the parts. This was a problem of achieving real co-operation and co-ordination so as to influence the mental attitudes of the students. He was anxious that Britain should try to meet the developing situation by action now, so as not to be forced to act later under pressure from influences outside the country.

Prof. R. L. Sproull, head of the Materials Science Centre, Cornell University, and chairman of the Advanced Research Projects Agency activity there, reviewed the situation in the United States. He recalled that some six years ago many currents of opinion seemed to be running in the same direction pointing to the absence of adequate materials for the many new technological projects, in particular atomic energy and astronautics. The problems came to a focus within the Atomic Energy Commission and there was a proposal to form a National Laboratory for Materials. It was soon realized that there were not enough men with the right background and attitudes to staff such a laboratory and urgent decisions were taken to provide training to produce this type of man for the future.

It was noticed that in some of the big industrial laboratories in the United States it was possible to bring sophistication from various scientific fields to bear on problems and frequently the outcome from this approach was strikingly successful. It was also noticed that students are more readily attracted to those subjects that contain the word 'science' in their titles. Even so, a very high proportion of graduates who were working on problems of materials had in fact been trained in high-energy physics. This was recognized as wasteful, and it was decided to establish a series of interdisciplinary laboratories in several university institutions devoted to materials science. There are now twelve such interdisciplinary laboratories supported by the Advanced Research Projects Agency, with two more supported by the National Aeronautics and Space Agency and an additional one supported by the Atomic Energy Commission.

University departments had not, in general, been equipped with sophisticated apparatus of the type students would eventually use for research and development in Government and industrial laboratories. Therefore, one objective was that university departments should be equipped to about the same standard as some of the best industrial laboratories. In response to Government support, the chosen university institutions agreed to produce more Ph.D.s, to undertake research which would be broadly in keeping with the trends in materials development and to use an interdisciplinary approach to research. They were in fact trying to produce a new breed of man and not merely to achieve a simple addition of disciplines. Prof. Sproull was in favour of the development of materials science courses without reference to existing disciplines although this had not, in general, been possible in the United States.

Prof. E. W. J. Mitchell (University of Reading) described how he had tackled the problem of achieving depth while covering the essential fundamentals required in materials research work. This could be achieved by a fairly ruthless pruning of the conventional physics course, leaving out treatment in depth of such topics as high-energy physics, electronics and optics, and streamlining the teaching in some other subjects. The objective was to try to impart to the students an understanding of some of the structure-sensitive phenomena and an appreciation that they could be studied in an intellectually stimulating fashion. Prof. Mitchell's undergraduate course forms one of three options within the school of physical sciences at the University of Reading.

Prof. D. A. Wright explained that because there was much activity in high-energy physics at Durham it had been appropriate to introduce applied physics and to concentrate on electrical materials in teaching and research. The University hopes eventually to introduce postgraduate courses in this field.

Profs. A. G. Quarrell and V. N. Douglas emphasized strongly the interdisciplinary nature of all technology. They pointed out the distinctions between solid-state physics and activities such as physical metallurgy and glass technology, which could not avoid the complexities of real industrial problems. Prof. Quarrell warned against thinking that the study of materials science was specifically a new feature. At Sheffield this had been the case for some time where the Faculty of Metallurgy included glass technology and refractories as well as metallurgy. He thought that technological subjects should stand in their own right as university disciplines and that they could not be adequately imparted in short postgraduate courses given to people who had not previously had some understanding of the complex situations involved.

Prof. R. W. Cahn (University College of North Wales, Bangor) presided at the second session when the discussion embraced "the relationship between materials science and other disciplines, the problem of financing materials science teaching and research, and the problem of university recruitment".

Prof. T. K. Ross (Manchester College of Science and Technology), speaking for chemical engineering, said that the relationship between materials science and chemical engineering might at first sight appear slight but was by no means unimportant. The chemical engineer tended to think in terms of constructional materials for process plants and the problem of environment usually represented corrosion. In his opinion, the postgraduate field had most to offer.

Mr. A. Kennaway (B.T.R. Industries, Ltd.) contended that mechanical engineers required to be better educated in materials science. They should know more about the plastic range in metals, the criteria for failure and the technical properties in general in relation to structure. The properties of other materials such as plastics were often investigated by chemists and physicists with the result that the available information was not in a form that the engineer could use. Mr. Kennaway could see no case for the unification of the technologies, as compared with the science of materials.

Prof. A. J. Wildschut (Technical University, Delft), said it was surprising, on reflexion, how little was known about materials. The civil engineer was interested in a wide range of materials—the 'big volume materials' such as clay, soil and stone, which must be cheap, and the 'small volume materials' such as brick, metal and wood. He quoted a number of novel applications and emphasized the importance of durability in structural materials which were difficult to use up to their physical limit. Dimensional stability was important in metals, for example, and stiffness in structure, while a weakness in an expensive joint could impair the success of a major civil engineering project. Improved knowledge of all materials of construction was important to the civil engineer.

Prof. E. H. Rhoderick (Manchester College of Science and Technology) described the courses in materials

science designed for electrical engineers with a bias towards electronics interests, which included subtle and complicated techniques and involved, for example, superconductors and cryogenic techniques. The courses presumed that the materials scientist was not essential for inventions but he was required for the development of inventions. Third-year electrical engineering students at Manchester were given an extensive course in properties of materials, including new materials. A further course was available at postgraduate level. The stimulus came from linking the materials work to electrical engineering.
